The Japanese were able in 18 months to overrun the area around Peiping, the central Yangtze Basin, and most of the coast of southern China. By the end of 1938 they controlled the richest portions of the country and exercised sway over nearly half its population. In uneasy cooperation with the Communists the Chinese central government was organizing itself for prolonged resistance, and, in fact, war was to continue for more than eight years. Nevertheless, the Japanese aggression seemed at the time to have been an overwhelming success. And in view of the association of the Japanese with the Germans (and after Nov. 6, 1937, with the Italians) in the Anti-Comintern Pact, their triumph seemed another score on the side of the totalitarian states, another encouragement to them, another warning to the democracies.

The Axis and the Anschluss.—Even before the Sino-Japanese War the French and British had begun to take some action. Military authorities in both countries estimated (probably erroneously) that the Germans had a long lead in preparations for war. To bring themselves abreast the French decided in October 1936 to undertake a four-year rearmament program, and the British followed their example. The two governments also gave fresh thought to the possibility of redressing the balance by finding allies. Aware of the isolationism of the United States, suspicious of Soviet communism, and apprehensive that in any case the army purges of 1937 might have weakened the USSR, they turned inevitably to the idea of allying themselves with Italy—of recreating the *Stresa* front. Mussolini, however, had been drawing closer to Hitler. After both independently gave aid to Franco, discussion arose about the possibility of cooperation in wider spheres. Hitler, who had prophesied a German-Italian entente in *Mein Kampf*, made the first overtures. In October 1936, the Italian foreign minister, Conte Galeazzo Ciano, visited Germany and arrived at vague understandings on common action against international communism. On November 1, reacting viscerally to the British decision on rearmament, the duce made a speech. In it he spoke of a "vertical line between Rome and Berlin" that was "not a partition but rather an axis round which all European states animated by the will to collaboration and peace can also collaborate." Seizing on his words, commentators soon coupled Italy and Germany as the Axis powers.

They were not yet formal allies. Indeed, from the French and British standpoint, it seemed that they were far from being so. After the settlement of the Ethiopian affair, Italy's paramount interests appeared once again to lie in the Danubian region. And it was there that Hitler seemed most likely to make his next move. He had continued to give strong backing to the Austrian Nazis. In February 1938, through pressure on Chancellor von Schuschnigg, he forced the appointment of Nazis to key posts in the Austrian government. He and they talked openly of an Anschluss: a political union. It remained to be seen whether Mussolini would react again as he had in 1934. The Italian dictator did in fact sound out the British govern-

Wide World

ment on the possibility of an accord. He did not ask that Britain guarantee support against Germany, but merely that it recognize his conquest of Ethiopia and reach an entente with him on Mediterranean issues. This would be enough, he implied, to enable him to stand up to Hitler on the Austrian question. Whether he was in earnest or not remains doubtful. In any event, Foreign Secretary Eden took the view that an understanding with Italy was impossible without the termination of Italian intervention in Spain. Although the majority of the cabinet disagreed with him and he resigned, there was so much support for his position in the House of Commons that the government felt compelled to go slowly.

Meanwhile, Hitler moved. On Nov. 5, 1937, he had disclosed his thoughts to some of his principal political and military subordinates. The next six to eight years, he said, would bring Germany to the peak of her relative power. Thereafter rearmament by other nations, coupled with the obsolescence of German weapons, would mean that any change would be for the worse. "Germany's problem could only be solved by means of force," he declared, and "it was his unalterable resolve to solve Germany's problem of space at the latest by 1943-1945." The first steps would be the conquest of Austria and Czechoslovakia. After that the schedule would depend on circumstances. Morally sure that Italy would not resist, he had made preparations to act against Austria. His demand for the installation of Nazis in key posts in that government was a first step. When Schuschnigg made a sign of defiance, announcing a projected plebiscite in which the Austrian people would register their desire to remain independent, Hitler sent an angry ultimatum demanding its cancellation. Encouraged by Schuschnigg's compliance, he then demanded that a Nazi be installed as chancellor. When rebuffed, he directed Dr. Arthur Seyss-Inquart, Austrian Nazi minister of the interior, to proclaim himself head of a provisional government and invite German intervention. This was done. German troops crossed the border early on March 12. On the following day, Anschluss was proclaimed, and on March 14 Hitler himself was in Vienna. Having received no encouraging reply from London, Mussolini had acquiesced, telling Hitler's envoy that "Austria would be immaterial to him." Since the British had taken the position even in 1934 that Austria was not a direct concern of theirs, they contented themselves with a strong diplomatic protest. The French, embroiled in a domestic crisis and having only a caretaker cabinet, were incapable of even contemplating action. In the series of successes of the dictatorships the conquest of Austria was the most rapid, the most complete, and the most feebly opposed.

Czech Crisis.—It was clear to all the world that Czechoslovakia was now in peril. German garrisons ringed its western frontiers, and the German press and radio thundered about persecution suffered by the German minority there. In the Sudetenland, where most of this minority resided, a constant clamor was maintained by Nazi sympathizers whose leaders plainly took their orders from Berlin. Reacting to evidence of German troop concentrations, the Czechs on May 20, 1938, ordered the mobilization of reserves along the German frontier. Their French ally stood by them, warning the Germans not to attack. The British ambassador in Berlin added reinforcement by reminding the German Foreign Office that

Britain was an ally of France, and the Soviet government declared that it would live up to its alliance with Czechoslovakia. This so-called May crisis proved short lived, for on May 22, Hitler sent to Prague assurances that he was not concentrating troops and that he had no aggressive designs.

Although this episode was frequently cited later as an instance in which firmness by the other powers had forced Hitler to back down, the fact was that the crisis was illusory. While the führer intended eventually to move against Czechoslovakia, it had not been in his mind to act so soon after the Anschluss. On April 21, he had ordered the High Command of the Armed Forces (OKW) to bring up to date plans for a Czech campaign, but the work was not completed until mid-May. Hitler was, in fact, giving his approval to this document on the very day when the Czechs mobilized, and the first words of his covering letter were, "It is not my intention to smash Czechoslovakia in the immediate future without provocation, unless an unavoidable development . . . within Czechoslovakia forces the issue." If the May crisis had any result, it may have been to anger Hitler and incline him to advance his timetable. His associates testified later that he was furious at having to give assurances to the Czechs, and on May 30 he revised his directive to read, "It is my unalterable decision to smash Czechoslovakia by military action in the near future." Perhaps, too, the false sense of having been at the very brink of war had a palsy effect on the governments that had momentarily seemed so firm.

In succeeding weeks and months the British showed an increasing disposition to arrange some appeasement of the Germans. Neville Chamberlain was now prime minister, having succeeded Baldwin on May 28, 1937, and he was strongly of the view that the Germans had many legitimate grievances, that it would not be in the interest of the world for the powers to insist obstinately on maintaining the status quo, and that every conceivable step should be taken to avert war. His position in the May crisis had actually been a good deal less firm than it seemed, and he took pains afterward to make this plain. Through newspaper leaks he let it be known that Britain saw merit in the German position on the Sudetenland. On Aug. 3, 1938, he dispatched the 1st Viscount Runciman to Czechoslovakia to devise a formula that might satisfy Hitler. On September 7, in a widely noticed editorial that was probably inspired by the government, the *London Times* went so far as to suggest that the Sudetenland might be allowed to secede and unite itself with Germany. Hitler had meanwhile fixed October 1 as the date on which German forces were to move on Czechoslovakia. By early September, increased agitation by the Sudeten Nazis and the German press and radio gave notice that some kind of climax was approaching. At a party rally in Nürnberg on September 12, Hitler delivered a tirade against the Czechs. Observers reported infantry and armored units moving to the frontiers, and this time there was no question of the fact.

Berchtesgaden and Bad Godesberg.—To avert the impending crisis, Chamberlain resolved to meet face to face with Hitler. Although he was 69 years old and had never been in an airplane before, he telegraphed the German dictator offering to fly over at once, and on September 15, Hitler met him at Berchtesgaden. There the prime

minister asked if Germany would be satisfied by the cession to her of the Sudetenland. When assured that this was the case, he promised to press such a solution on the French and the Czechs. He returned to London sure that a basis for peace had been found and convinced, too, as he noted in a private memorandum, "that here was a man who could be relied upon when he had given his word." On September 18, the premier and foreign minister of France, Edouard Daladier and Georges Bonnet, came to the British capital. Although in the past they had said repeatedly that France would stand by Czechoslovakia, the question of whether or not to repeat this assurance had been debated in their cabinet throughout the day of September 13 without a decision being reached. Their military advisers had warned that the French armies alone could not carry out offensive operations, and that France would still be defenseless in the face of German air attacks. The Czech Army, though 800,000 strong, was not credited with ability to maintain prolonged resistance. Only Soviet troops were in a position to come directly to the aid of Czechoslovakia, and although the USSR had indicated that it would dispatch such troops, they could arrive only by way of Rumania or Poland. Both of these countries had indicated firmly that they would not grant rights of passage, and the Poles had said on September 12 that they would not honor their alliance with France if France were swept into war on account of Czechoslovakia. Daladier and Bonnet were eager therefore to explore any road that might lead to peace. They gave approval to the formula that Chamberlain had brought back from Berchtesgaden, and on September 19 the British and French governments joined in urging the Czechs to accept it.

The initial response from Prague was negative. The government of President Eduard Beneš was well aware that in sacrificing the Sudetenland Czechoslovakia would lose not only valuable resources and industrial plants but also her only natural defenses against Germany, and Beneš had thus far employed every device to prevent its loss. But this initial response was not the final one. Fearful as they were of the Germans, Czech leaders were even more frightened of the Russians. Further dispatches from London and Paris impressed on them the fact that even if the Western democracies went to war in their behalf, British and French troops would not come to Czecho-

slovakia. Soviet troops, on the other hand, might do so. There were persistent hints from Moscow that they would force their way through Rumania or Poland. The general feeling among Czech leaders was that, if so, they would never withdraw. The cabinet, or at least some part of it, decided that the course of wisdom was to accept the sacrifices urged by the British and French. Declaring that he was acting with the knowledge of Beneš, Premier Milan Hodža communicated secretly with Bonnet, requesting a statement that France would not defend Czechoslovakia if the Anglo-French proposals were rejected. With this in hand, he indicated, it would be possible for the cabinet to justify acceptance of them. Bonnet complied, and on September 21 the Czechs gave notice that they would agree to the terms which Chamberlain and Hitler had devised at Berchtesgaden.

Delighted, Chamberlain arranged for another meeting with the führer, this time at Bad Godesberg on the Rhine. When he arrived on September 22, however, he found to his dismay that the Berchtesgaden terms no longer satisfied Hitler. The German now demanded not only that the Sudetenland be ceded to Germany but that it be turned over to her immediately: before 2 P.M. on September 28. Since Chamberlain had envisaged a survey of the area by an international commission and German-Czech negotiations to determine new boundaries, this meant the ruin of all he had arranged. On September 23, he left for home, heavyhearted and doubtful that war could be averted.

Munich.—For the next few days, Europe seemed on the verge of war. The Czechs mobilized. Daladier and Bonnet came again to London, where they were assured more or less definitively of British support. They in turn promised backing to the Czechs. On September 26, Hitler spoke at the Sportspalast in Berlin, proclaiming in violent language that the Sudeten issue would be solved in a matter of days, if necessary by force. On the following day, the British cabinet ordered partial mobilization. Air-raid shelters began to go up in London. Chamberlain expressed his attitude in a radio address to the British people. "How horrible, fantastic, incredible it is that we should be digging trenches and trying on gas-masks here because of a quarrel in a faraway country between people of whom we know nothing!" Grasping at straws, he wrote again to Hitler and sent a message to Mussolini requesting Italian influence on behalf of a peaceful settlement. President Roosevelt on September 26 appealed to Hitler to negotiate with the other Europeans.

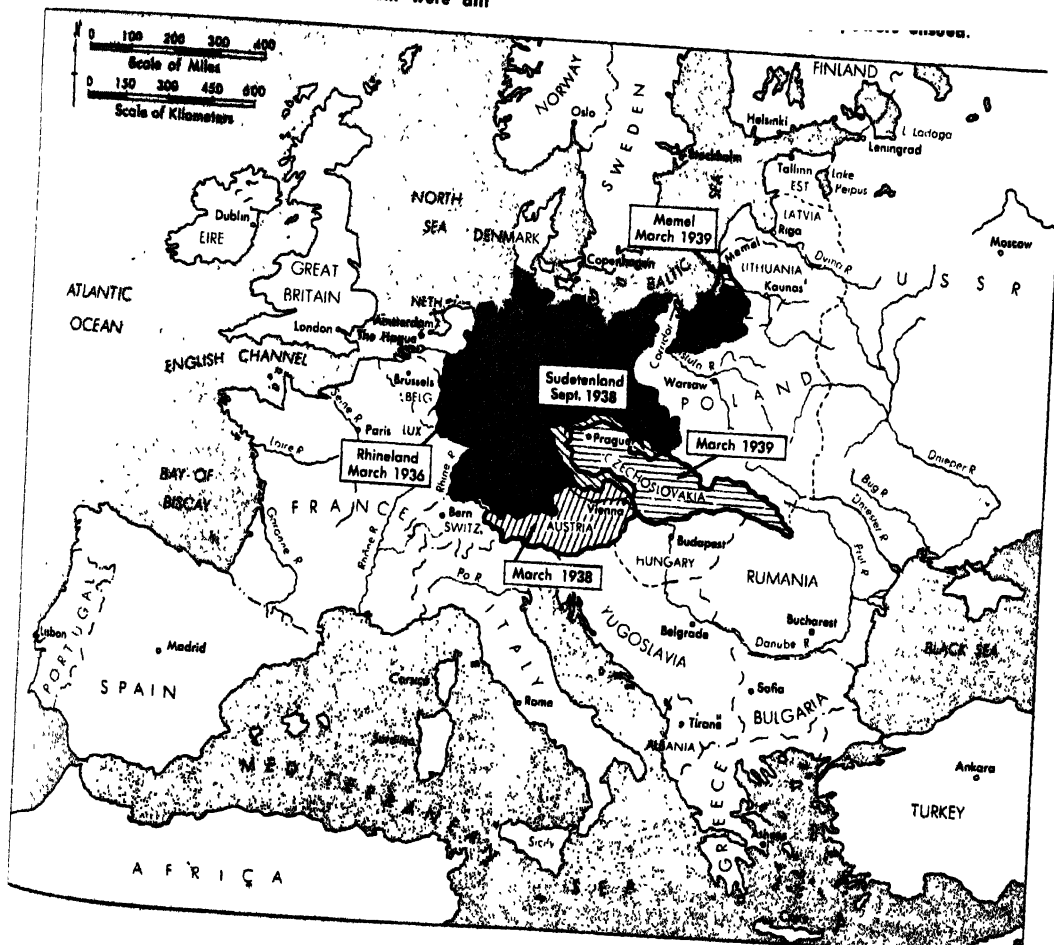

While the German leader had hoped that France would not act and had counted on the British not to do so, he told intimates that he was ready to make war if it proved necessary. His generals were almost unanimous in holding that Germany was not in fact ready to fight against Czechoslovakia, France, Britain, and probably the USSR, but Hitler appeared to have little regard for their opinions. On the morning of September 28, he seemed prepared to carry out his threat, come what might. Before the 2 P.M. deadline, however, he received Chamberlain's new message, a communication from the French ambassador which indicated that France would go to almost any length to avoid war, and a message from Mussolini proposing an Anglo-French-German-Italian conference to compose the issue. Informing the Western governments that he would post-

The conference met at Munich on September 29-30. A new plan was put forward by Mussolini. Since it had actually been drawn up in Berlin, Hitler said that he found it a satisfactory basis for negotiation. Chamberlain and Daladier accepted it with few amendments. The four leaders affixed their signatures, and Chamberlain returned to London to declare that he brought back "peace with honour," adding, "I believe it is peace in our time." The Munich agreement stipulated that the Germans should occupy the Sudetenland by October 10; that an international commission, representing the four powers and Czechoslovakia, should arrange the transfer and draw new boundaries not only there but also on the Czech-Polish and Czech-Hungarian frontiers; and that afterwards all four powers would guarantee these new frontiers. Dominated by the Germans, the commission awarded to Germany all the border area had been shown as German in the Austro-Hungarian census of 1910. This included approximately 10,000 square miles and 3,500,000 persons. The commission also approved Polish seizure of Teschen (Cieszyn, Těšín) region, which took place on October 2, and on November 2 awarded

In western European capitals, even while joy over Munich was at its height, there was some suspicion about Hitler's future intentions. Daladier was skeptical from the outset that the settle-

ment would last. Reports from intelligence sources soon aroused similar doubts in members of the British government. Official and public opinion in both countries veered toward the view that appeasement had been given its final trial—that the Munich accords were the last concessions that could be made, and that further demands by Hitler would call for forthright opposition. In March 1939, this changed mood was put to the test. Hitler had paid no attention to diplomats' warnings of it. The French had signed with him on Dec. 6, 1938, a joint declaration guaranteeing the Franco-German frontier and promising the settlement of future differences by consultation. The British had made overtures for economic accords. Though meant as earnestness of desire to make the Munich settlement work, these gestures were interpreted by Hitler as further evidence of spinelessness, and when he next acted, he did so more brazenly than on any occasion in the past.

Having given encouragement earlier to Slovakian separatists, on March 11, 1939, he sent Austrian Nazis to Slovakia to order the Slovaks to proclaim their independence and ask him to become their protector. In the meantime, the Czech president, Emil Hácha, asked to see the führer. He was invited to Berlin and given an audience in the early morning hours of March 15. An almost incredible scene ensued. Hitler told Hácha that there were only two choices: Czechoslovakia could ask to be occupied peacefully, or it could be invaded and its people made to suffer. The führer's deputies literally chased Hácha around a table, trying to force him to sign a proclamation requesting establishment of a German protectorate. When the aged Czech fainted, he was revived with injections. Finally he signed. Hitler immediately ordered his troops to move, and on March 16 he was in Prague, proclaiming that Czechoslovakia no longer existed. Both the Czech and the Slovakian regions became German protectorates. In accordance with a prior understanding the largest part of the Carpatho-Ukraine was turned over to Hungary.

The reactions in Western capitals were mixed. The fact that Hácha had invited German intervention made it hard for the French and the British to do more than protest the violation of the spirit of Munich. On the other hand, even the firmest believers in appeasement were shocked by Hitler's seizing new territory after having said so vehemently that he had no further ambitions and especially by his taking into the Reich 10,000,000 persons who were not of German nationality. The majority of the French cabinet now agreed immediately that, when he moved again, Hitler would have to be stopped by force. At Birmingham on March 17, Chamberlain declared that if the recent German action proved merely a prelude to other attacks on small states, Britain would join in resisting "to the utmost of its power."

The nation most likely to be Hitler's next target was Poland. On January 9, Hitler had renewed his demands with regard to Danzig, coupling with them a secret communication suggesting that Poland might in return obtain eventual cessions of territory in the Soviet Ukraine. On February 1, the Poles refused. On March 21, however, Hitler notified them in threatening language that the Danzig issue would have to be settled. Two days later, German troops seized Memel. The French and British had already indicated that they were prepared to negotiate an alliance with Poland. The chief stumbling block

was the question of whether or not the USSR should be included. Through the commissar for foreign affairs, Maksim M. Litvinov, the Soviets had expressed a desire to be a party to the alliance. Polish leaders, however, looked on this offer with apprehension fully equal to that which had been shown by the Czechs. While exhibiting eagerness for ties with the British and French, they still said firmly that they would not permit Soviet troops to cross their soil. Although most members of the French and British cabinet wanted to form a common front with Poland and the USSR, they concluded that it would be dangerous to wait for a change in the Polish stand. On March 23, as a warning to Hitler, the two governments had declared that they would defend Belgium, the Netherlands, and Switzerland against any attack. This pledge had been made without any *quid pro quo*, and Daladier and Chamberlain decided that their simplest course was to follow the same procedure with regard to Poland. The British prime minister asked if the Poles would have any objection. They said no, and on March 31, Chamberlain announced in the House of Commons:

In the event of any action which clearly threatened Polish independence and which the Polish government accordingly considered it vital to resist with their national forces, His Majesty's Government would feel themselves bound at once to lend the Polish Government all support in their power. They have given the Polish Government an assurance to this effect. I may add that the French government have authorized me to make it plain that they stand in the same position in the matter. . . .

On April 7, Mussolini, imitating Hitler's tactics, invaded Albania. The British and French governments on April 13 extended their guarantee to Greece and Rumania. Abandoning their earlier policies altogether, they now stood ready to go to war automatically if the dictators committed new acts of aggression.

Nazi-Soviet Pact.—The Western powers were still desirous of having the USSR on their side. All hope of attaching Italy to their cause had disappeared. On January 4, Mussolini had told Hitler that he was ready to negotiate a comprehensive alliance. Although this so-called Pact of Steel, pledging each nation to join the other immediately in war, was not completed until May 22, Mussolini meanwhile made no secret of where he stood. Chamberlain and Daladier had received some encouragement from the United States. Roosevelt had opened a campaign to repeal the Neutrality acts of 1935–1937 so that American supplies would be available to Britain and France if war came, but he was to find it impossible for the time being to carry Congress with him. In any event, there was no likelihood whatever of early American intervention in their behalf. If there was to be another power allied with them, it could only be the USSR.

Despite Polish opposition, the French and British had continued to discuss a pact with the Soviets. On April 15, the French suggested that the two Western powers and the USSR sign a treaty containing pledges of mutual assistance in the event of war. Thus, while the Soviets would not have any engagement with Poland, they would be obligated to fight for her if the French and British did so. After a long delay resulting partly from concern about Poland's role, partly from distrust of the Soviets, and partly, in all probability, from latent hope for a war between Nazis and Communists in which the democracies could stand aside, Chamberlain's cabinet agreed to the French plan. The proposal was made to

the Russians, and on May 27 negotiations began in Moscow. Troubled from the outset by the issue of whether or not the three-power agreement should explicitly recognize a Russian right of passage through Poland, the negotiations eventually foundered. They were finally suspended on Aug. 21, 1939.

In the meantime, other negotiations had been in progress between the Soviets and the Germans. After giving various subtle indications that Munich had undermined his hope of cooperation with the Western powers, Stalin on March 10 made a speech summarizing the principles of his foreign policy as:

(1) To continue to pursue a policy of peace and consolidation of economic relations with all countries.

(2) . . . Not to let our country be drawn into conflict by warmongers, whose custom it is to let others pull their chestnuts out of the fire.

On May 3, Litvinov was replaced by Vyacheslav M. Molotov, a man who had had no part in the effort to win alliances with the democracies. Speaking with the German ambassador on May 20, the new foreign commissar remarked that mutually profitable economic agreements might be reached if a suitable "political basis" were established.

Although Hitler understood these hints, he was slow to act on them. Not until late in May did he authorize exploratory conversations about a trade pact and related matters. After these went on for some weeks without result, on June 29 he abruptly ordered that they be broken off. On July 18, he learned of Russian proposals for resumption of the talks. Eight days later, his foreign minister, Joachim von Ribbentrop, spent an evening sounding out some Russian officials who were in Berlin. Encouraged by the results of these and other conversations, Hitler decided on a bold gamble. On August 14, he had Ribbentrop propose to the Russians "a speedy clarification of German-Russian relations . . . in due course clarifying jointly territorial questions in Eastern Europe." Now the supplicated rather than the supplicants, the Soviets raised a number of practical issues. In each instance, Hitler responded satisfactorily. By August 20, terms had been agreed on, and on August 23, Molotov and Ribbentrop signed a nonaggression pact in Moscow. The published text bound both governments to refrain from aggressive action or attack against each other, to lend no support to a third party should either "become the object of belligerent action" by one, and to join in no "grouping of Powers whatsoever which is aimed directly or indirectly at the other Party." A secret protocol stipulated that if "territorial and political transformation" should take place in northeastern Europe, the boundary between German and Soviet spheres should follow the northern border of Lithuania and the line of the Narew (Narev), Vistula (Visla), and San rivers in Poland.

Thus was a temporary diplomatic revolution effected. The Nazi and Soviet dictatorships became allies. Among the great powers only the British and French remained as potentially active opponents of German expansion. After the signature of the pact with the USSR, Hitler reportedly exclaimed, "Now, I have the world in my pocket!"

Final Crisis.—On April 3, Hitler had directed his generals to prepare a plan of campaign against Poland, with September 1 as its probable starting date. On May 23, in a conference with top-ranking officers, he disclosed that his intention

was to use the Danzig question as a pretext and "to attack Poland at the first suitable opportunity." Meeting Mussolini's foreign minister at Obersalzberg on August 12–13, Hitler stated that he intended to move against Poland before the end of the month, and that he was confident that Britain and France would not intervene. He expressed this conviction to others. After learning that the pact with the Soviets would become a reality, however, he convoked his generals at Obersalzberg and, in the course of a long, rambling speech, told them that while he did not foresee war in the west it was a risk that had to be run. In any event, he said, delay worked to Germany's disadvantage. If the British and French did nothing about Poland, he intended to strike against them soon after the Polish campaign was over. Economically and militarily, he said, they would profit from further respite while Germany would not. He ordered that the armies be ready on August 26 to move against Poland and, if necessary, to hold the western frontier against an Anglo-French attack. But on August 25, two days after the Nazi-Soviet Pact, the French warned him once again that they would stand by Poland, and on the same day Chamberlain announced the signature of a formal Anglo-Polish alliance. Hitler wavered. Saying that he needed time for negotiation, he ordered the postponement of the operation.

His chosen pretext had been alleged grievances of the German population in Danzig. Clamor there for annexation by Germany and for establishment of road and rail corridors had been augmented since July as a result of the dispatch to the city of several hundred Nazi *agents provocateurs*. Citing the evidence of this agitation, Hitler addressed to Chamberlain a long appeal for understanding and sympathy. Obviously hoping against hope that a peaceful solution would emerge, the British prime minister pressed the Poles to make every concession. They agreed reluctantly to negotiate about the issues Hitler raised. When their ambassador in Berlin gave notice to this effect, however, Hitler refused to deal with him unless he had full powers to reach a settlement on the spot. Exploiting this pretext, he declared to the British and French governments that it was not he but the Poles who were rejecting diplomacy. When the government in Warsaw ordered mobilization on August 30, the German press and radio cried that it was planning an attack. On the following day, there occurred a small incident on the German side of the Polish frontier. According to Hitler's subsequent speech, Polish soldiers attacked a German radio station at Gleiwitz (now Gliwice). Actually the attackers were Germans outfitted in Polish uniforms, commanded by an SS officer, and acting on orders from Berlin.

Hitler had already given the final directive for the invasion to begin at dawn on September 1. It was well under way before he delivered a radio address throwing all blame on the Poles and saying that he had had to meet force with force. When the French and British demanded that he recall his troops, he refused. On September 3, Chamberlain and Daladier gave formal notice to Germany that a state of war existed. The long armistice of 1918–1939 was over.

3. Early Campaigns

POLAND

Approach to Conflict.—On March 25, 1939, 10 days after he had completely dismembered Czechoslovakia, Adolf Hitler told the chief of the High Command of the Armed Forces (*Oberkommando der Wehrmacht* or OKW), Col. Gen. (later Field Marshal) Wilhelm Keitel, and the commander in chief of the army, Col. Gen. (later Field Marshal) Walther von Brauchitsch, that the time had come to consider solving the Polish problem by military means. A week later, on April 3, Part 2 of the annual directive for the German armed forces, drafted by Hitler himself, set forth a strategic outline for an attack on Poland to be prepared by Sept. 1, 1939. On April 28, in his first open move, Hitler abrogated the Polish-German nonaggression treaty of 1934 and declared that the issue of Danzig (Gdańsk) must be settled. Hitler's turning against Poland surprised no one. On March 31, the British government, attempting to forestall the German dictator, had given a unilateral guarantee of Poland's territorial integrity. (France had a military alliance with Poland dating back to 1921.)

Without hesitating, Hitler pressed forward. At a staff conference held on May 23, he stated that a repetition of the Czech affair was not to be expected. Further successes and the expansion of German *Lebensraum* (space for living) could not be achieved without bloodshed. There would be war. Observers had noted after the Munich Conference (q.v.) of 1938 that the negotiated settlement had angered Hitler. He had wanted a chance to test the new Wehrmacht in action, and he was now determined to have it against Poland. This was the new element in the crisis which Hitler carefully nurtured through the spring and summer of 1939. He did not wish another Munich, but he did wish to cajole, frighten, or simply confuse the British and French sufficiently to keep them from intervening in the neat, small war that he intended to have with his neighbor on the east.

Poland, not a great power, with a population of 35,000,000 was also not a minor nation. In maintaining its national existence against foreign threats, it labored under several handicaps: approximately 10,000,000 of its people were non-Polish, its industrial base was weak, and it included in its boundaries on the north (Polish Corridor, q.v.) and on the east territory to which Germany and the Soviet Union could lay strong claims on ethnic and historical grounds. Polish policy as conducted by President Ignacy Mościcki and Foreign Minister Józef Beck was to stand firm against all of Hitler's demands. The Polish government drew encouragement from the French alliance, the British guarantee, and, apparently, from an underestimate of German strength and an overestimate of its own capabilities.

In the game Hitler started, the Soviet Union could, if it wished, play the last trump. Fear of a two-front war haunted the German military, and even Hitler would not at this time have risked fighting both the Western powers and the Soviet Union. In mid-April 1939, the USSR began negotiations with both sides. The British and French courted the Russians, but Joseph Stalin was not

eager for trouble with Germany. The Russians made the overtures to Germany, first suggesting that the ideological conflict between nazism and communism need not be a bar to a general agreement, and then hinting that the Soviet Union would consider another partition of Poland. Hitler was cool toward these proposals until he realized that the Russians were not merely trying to make use of Germany to raise the price they could extract from the British and the French. His bargaining position was strong: the Soviet Union might have to fight for the Western powers, but all it needed to do for Hitler was to remain neutral and gather in the spoils. How well the Russians appraised the situation was demonstrated on May 3, when Maksim M. Litvinov, a Jew and a long-time advocate of international measures to restrain aggression, was suddenly dismissed as commissar of foreign affairs and replaced by Vyacheslav M. Molotov.

In July 1939, under the guise of conducting summer maneuvers, strong German forces moved into assembly areas on the Polish border. Others were sent to East Prussia on the pretext that they were to take part in celebrating the twenty-fifth anniversary of the Battle of Tannenberg (now Stebark). In the first three weeks of August, German-inspired civil disorders broke out in Danzig and the Polish Corridor, and the remaining units scheduled to participate in the attack moved up to the border. On August 22, Hitler assembled the generals who would command the larger units and told them that the time was ripe to resolve the differences with Poland by war and to test the new German military machine. He predicted that Great Britain and France would not intervene. He intended to begin the attack on August 26.

In Moscow on the night of August 23, Foreign Minister Joachim von Ribbentrop agreed to the final wording of the German-Soviet Nonaggression Treaty, later known as the Nazi-Soviet Pact. A secret protocol placed Finland, Estonia, and Latvia in the Soviet sphere of interest and Lithuania in the German. The border of the Soviet and German spheres in Poland was established on the Narew (Narev), Vistula (Visla), and San rivers. Because time was pressing for Germany, the treaty was to go into effect as soon as it had been signed.

In a last attempt to intimidate Hitler, Great Britain announced on August 25 that she had entered into a full-fledged alliance with Poland. On the same day, Hitler's ally Benito Mussolini informed him that Italy would not be able to take part militarily in any forthcoming war. These two reverses were not significant enough to deter Hitler, but they did cause him to hesitate. He canceled the August 26 starting date for the attack. For the next six days all of his moves were directed toward two objectives: the division of Poland and the West by various schemes and proposals for negotiations which he knew the Poles would not accept; and the undermining of French and British confidence by means of the recent agreement with the Soviet Union.

On August 31, Hitler signed Directive No. 21 for the Conduct of the War. During the night, SS units staged "incidents" along the border, of which the most notorious was an alleged raid on the radio station at Gleiwitz (now Gliwice) in Silesia. Before sunrise on the next morning, Sept. 1, 1939, the war began as the German armies marched into Poland. Two days later, when Great Britain and France declared war, Hitler said to

Motorized German soldiers take diverging paths near Bydgoszcz, captured on Sept. 3, 1939, in the Nazi invasion of Poland.

German War Plan.—The fundamental concept of the German plan was to fight a short war that would be over before the British or French armies could get into action—over, in fact, before the Western powers could even make up their minds to fight. The plan was given its final form in an operation order issued by the Army High Command (*Oberkommando des Heeres* or OKH) on June 15. The order provided for two groups of armies, Army Group North commanded by Col. Gen. (later Field Marshal) Fedor von Bock and Army Group South under Col. Gen. (later Field Marshal) Gerd von Rundstedt.

Army Group North was to strike eastward from Pomerania (Pomorze) into the Polish Corridor with one of its two armies, the Fourth Army. The other, the Third Army, would strike westward from East Prussia into the corridor and southward toward Warsaw (Warszawa). When the armies had made contact in the corridor, they would both turn their full strength toward the capital. Army Group South, with the Eighth, Tenth, and Fourteenth armies, was to advance to the northeast from Silesia and Slovakia. The Tenth Army, the strongest of the three, would strike directly toward Warsaw, while the Eighth and Fourteenth armies covered its left and right flanks, respectively. The junction of the Tenth Army with elements of Army Group North at Warsaw would complete the encirclement of any forces in western Poland that had not been destroyed before then. This presumably would end the war. Bock proposed extending the arms of the encirclement east of Warsaw to prevent Polish troops' escaping into the Pripyet (Pripyat) Marshes, but nothing was done about this suggestion until after the campaign had begun.

The strength of Army Group North was 630,000 men; that of Army Group South, 886,000. Army Group North was supported by the First Air Force, which controlled 500 bombers, 180 dive bombers (Stukas), and 120 fighters. The Fourth Air Force supported Army Group South with 310 bombers, 160 dive bombers, and 120 fighters. The Air Force High Command (*Oberkommando der Luftwaffe* or OKL) held in reserve 250 Ju-52 transports for paratroop operations. The navy intended to use the World War I battleship *Schleswig-Holstein*, 3 cruisers, and two flotillas of destroyers to bombard shore installations at Gdynia and Hel (Hela).

Polish Defense Plan.—The one chance that Poland might have had to counter the German invasion successfully was to fight a delaying action

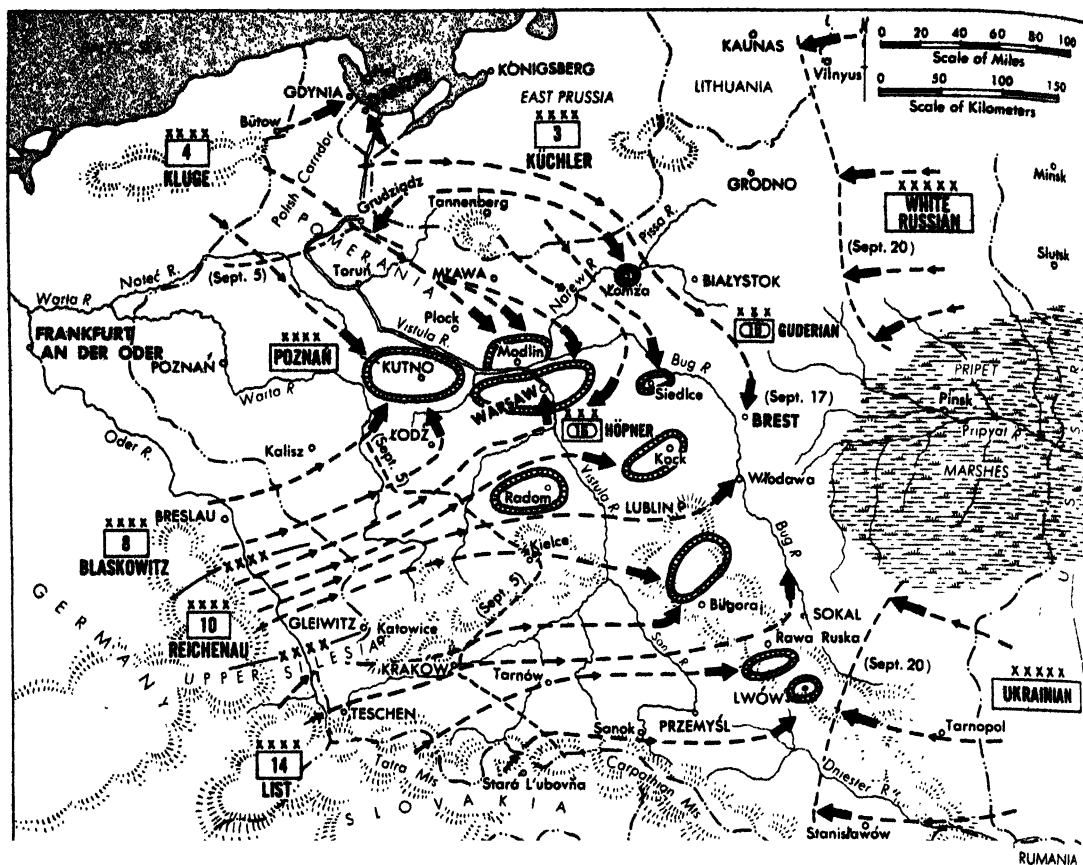

back to the Narew-Vistula-San line and to hold there until the Western powers could bring their forces to bear. This strategy would, however, have sacrificed the country's industrial base and so carried with it the seeds of eventual defeat. The Polish General Staff chose instead to defend all of its frontiers with seven armies and several smaller groupings in territorial deployment. It thereby eliminated at the outset the possibility of concentrating its strength at the most gravely threatened points. The planners apparently believed that the war, following older patterns, would begin with border skirmishes that would only gradually evolve into full-scale battles.

The Polish commander in chief was Marshal Edward Smigly-Rydz, inspector general of the armed forces. The army's full potential strength was about 1,800,000 men. Mobilization began in July, and apparently more than 1,000,000 men were called up, about 800,000 of them west of the German-Soviet demarcation line. Most of the weapons in the army's stocks dated from World War I, and its armor, except for a few light tanks, consisted of some companies of armored scout cars. The air units had 935 aircraft, less than half of which were modern. The navy consisted of 4 destroyers, 5 submarines, and some smaller craft.

Campaign.—On the morning of September 1, the Luftwaffe struck at the Polish airfields, destroying nearly all of the planes before they could get off the ground. It then set about systematically disrupting the railroads and lines of communications. Before the day ended, the Polish leadership was helpless. Mobilization could not be completed, and large-scale troop movements were impossible.

The first phase of the campaign, the breakthrough on the borders, ended on September 5. By September 7, the point of the Tenth Army was 36 miles southwest of Warsaw. The Eighth Army on the left had kept pace, executing its mission of protecting the flank, while the Fourteenth Army on the right had captured the Upper Silesian industrial area. By September 5, the two armies in Bock's Army Group North had cut across the corridor and had begun turning to the southeast, and two days later elements of the Third Army reached the Narew 25 miles north of Warsaw. The Poles fought gallantly, but cavalry was no match for tanks. On September 6, the Polish government left Warsaw for Lublin; later it moved close to the Rumanian border, which it crossed on September 16.

The second phase of the campaign completed the destruction of the Polish armed forces. According to the German plan, this was to have been

Map 2. CONQUEST OF POLAND (Sept. 1–Oct. 6, 1939). Adolf Hitler's occupation of Czechoslovakia exposed Poland's vital industrial complexes west of the Vistula and San rivers to German attack from three directions—north, west, and south. The extended Polish defenses along the border were easily pierced by the new German blitzkrieg. Though the Poles fought valiantly, they were forced to capitulate between the German pressure from the west and the Soviet advance from the east. The Ribbentrop-Molotov Line demarcating the German and Soviet areas of influence, mentioned in section 14. *Diplomatic History*, ran along the eastern border of Lithuania, thence along the Pissa, Narew, Vistula, and San rivers; the Curzon Line extended from the southern tip of Lithuania southward to the Bug River near Brest, thence southward along the Bug, turning west at Sokal, and then south-southwestward to the Czechoslovakian border.

accomplished in a single giant encirclement west of the Vistula. After intelligence reports indicated that the government and large numbers of Polish troops had fled across the river, the plan was changed in accordance with Bock's earlier proposals. The OKH, on September 11, ordered a second deeper envelopment, reaching eastward to the line of the Bug (Western Bug) River.

In the meantime, the closing of the inner ring at Warsaw had created the first and only genuine crisis of the war. The Polish Poznań Army, bypassed in the first week, at the beginning of the

second week felt the German pincers closing behind it. Turning around, it attempted to break through to Warsaw. For several days after September 9, staffs of the German Eighth and Tenth armies were put to a severe test as they swung some of their divisions around to meet the attack coming from the west. The Poles did not break through, however, and the ring gradually closed. On September 19, the Poznań Army, numbering 100,000 men, surrendered, ending the last resistance by a major Polish force.

The most spectacular feature of the outer envelopment was the advance of Gen. (later Col. Gen.) Heinz Guderian's panzer corps from East Prussia across the Narew to Brest (Brest-Litovsk), which it took on September 17. Elements of the corps then continued past the city to make radio contact with the Tenth Army spearhead at Włodowa, 30 miles to the south.

The war ended for all practical purposes on September 19. The fortress at Lwów (now Lvov) surrendered two days later. Warsaw itself held out until September 27. Modlin capitulated on September 28, and the last organized resistance ended on October 6, when 17,000 Polish troops surrendered at Kock. In the whole campaign the Germans took 694,000 prisoners, and an estimated 100,000 men escaped across the borders into

Lithuania, Hungary, and Rumania. The Germans lost 13,981 killed and 30,322 wounded; Polish losses will probably never be known.

Soviet Intervention.—Hastening to end the war before the Western powers could act, the Germans on September 3 requested the Soviet Union to move against Poland, but the Russians were not ready. The German speed had taken them by surprise. After the German ambassador in Moscow submitted a second request on September 10, the Soviet government apparently became concerned lest the war end before it could enter it and the Germans refuse to honor the secret protocol and evacuate the territory east of the demarcation line.

On September 17, two Soviet army groups, the White Russian Front in the north and the Ukrainian Front in the south, each with two armies, marched into Poland. They met little Polish resistance and concentrated their efforts on shepherding the Germans out of the Soviet zone. A last-minute German attempt to secure control of the oilfield south of Lwów in the Soviet zone had aroused suspicion. Approximately 217,000 Polish troops fell prisoner to the Russians. Many of them survived to fight Germany again either in the west or in Soviet service, but some thousands, mostly officers, found their graves in Katyn Forest.

Partition.—In formulating the secret protocol to the nonaggression treaty, both Germany and the Soviet Union had assumed that a truncated independent Polish state would be allowed to survive. On September 25, however, having made a hint to this effect six days earlier, Stalin proposed that the conquerors divide Poland between them. In Moscow, on September 28, Ribbentrop signed a Soviet-German treaty of friendship. A secret protocol revised the demarcation line. Germany received the Province of Lublin and the Province of Warszawa eastward to the Bug River, and as compensation the USSR included Lithuania in its sphere of influence. The Soviet Union also agreed to deliver to Germany 300,000 tons of crude oil annually, the estimated output of the Polish fields. The revision placed the Soviet border approximately on the Curzon Line (q.v.) and gave Germany nearly all of the ethnically Polish territory. On the same day, Ribbentrop and Molotov issued a statement claiming that the settlement had created a basis for a lasting peace in eastern Europe and calling for an end to the war between Germany and the Western powers.

FINLAND: THE WINTER WAR

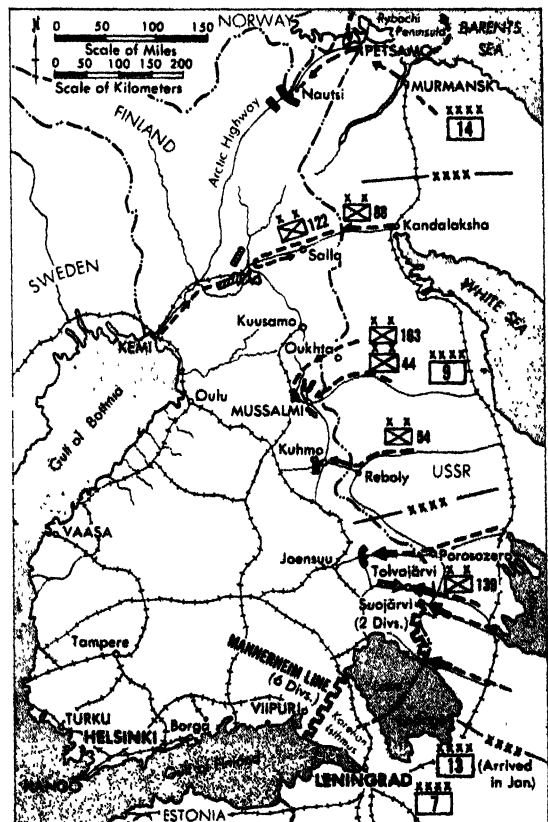

Beginning in the last two weeks of September 1939, the Soviet Union forced the three Baltic states, Estonia, Latvia, and Lithuania (qq.v.), to enter negotiations leading toward mutual assistance treaties granting rights to station Soviet troops and build Soviet bases on their territories. On October 5, the day Latvia signed its treaty, the Soviet government extended its diplomatic offensive to the north with a demand that Finland send plenipotentiaries to Moscow to negotiate political questions raised by the outbreak of the war. When the negotiations began on October 12, the Russians demanded a mutual assistance pact, a 30-year lease on a base at Hangö (Hanko), several islands in the Gulf of Finland, the western half of the Rybach Peninsula, and a broad strip of Finnish territory on the Karelian Isthmus. The

talks continued into November without producing agreement on the two main questions: Hangö and the Karelian Isthmus.

On November 26, the Russians staged an "incident," an alleged Finnish artillery attack, at Mainila on the Karelian Isthmus. Two days later, they abrogated their nonaggression treaty with Finland, and on November 30 opened the war with heavy air raids on Helsinki and strong attacks by ground forces at several points from the border north of Leningrad to the Arctic Ocean. On December 1, in (as it developed) an extremely premature move, the Soviet government announced that it had created a People's Democratic Republic of Finland under an old-line Bolshevik, Otto W. Kuusinen.

The lengthy preliminaries had given the Finnish Army ample time to complete the mobilization that it had begun on October 14. During the summer volunteers had started building field fortifications on the Karelian Isthmus, but nothing resembling the mythical "Mannerheim Line," which the Russians later invented to excuse their reverses. Finland mobilized 9 divisions and some single companies and battalions, or a total of 175,000 men. Plans had called for 15 divisions,

Map 3. SOVIET-FINNISH WAR (Nov. 30, 1939–March 12, 1940). The refusal of the Finns to accede to the territorial demands of the USSR brought on a Soviet offensive along the entire border. Though hopelessly outnumbered, the skillful Finns administered to the attackers several embarrassing reverses and frustrated them for several months. After a pause to reorganize and bring up additional forces, the Russians launched an attack by two huge armies up the Karelian Isthmus and against the Finnish Mannerheim Line. Overwhelmed by sheer power, the Finns were forced to capitulate.

but lack of weapons and equipment made this goal unattainable. In the course of the war, Finnish strength rose to about 200,000 men, and foreign volunteers, including a 300-man Finnish-American Legion, added another 11,000. The Lotta Svärd, an auxiliary force of 100,000 women, performed invaluable service in relieving men for frontline duty.

The Soviet High Command deployed four armies under the command of Gen. (later Marshal) Semyon K. Timoshenko on the Finnish frontier: the Seventh Army on the Karelian Isthmus, the Eighth Army north of Lake Ladoga, the Ninth Army in the Repoly (Repola)-Ukhta (Uhtua)-Kandalaksha (Kannanlahti) sector, and the Fourteenth Army on the Arctic coast. The total Soviet troop strength was about 1,000,000 men in 30 divisions. Approximately 1,000 tanks and 800 aircraft lent weight to the offensive.

The Finnish commander in chief, Field Marshal (later Marshal of Finland) Baron Carl G. E. Mannerheim, assembled 6 of his divisions on the Karelian Isthmus, stationed 2 divisions on a short line north of Lake Ladoga, and held 1 division in reserve. Nearly 600 miles of frontier northward to the Arctic coast could be screened only by scattered companies and battalions. Mannerheim had no choice but to mass his forces on the isthmus, the most direct route into the heartland of Finland, the narrow coastal strip between Helsinki and Viipuri (now Vyborg).

Most alarming for the Finnish High Command were the strength and speed with which the Soviet forces moved against the long frontier north of Lake Ladoga. In what at the time seemed a near miracle, two Finnish regiments under Col. (later Gen.) Paavo Talvela beginning on December 12 attacked and destroyed the Soviet 139th Division at Tolvajärvi (now Tolvayarvi), and then defeated the 75th Division. In a nearly month-long battle that began on December 11, a second small force under Col. (later Gen.) Hjalmar F. Siilasvuo encircled the Soviet 163d Division at Suomussalmi and destroyed the 44th Division, which had come to break the encirclement. These victories put an end to Russian attempts to sweep around Lake Ladoga from the north and to cut across the waist of Finland to the Gulf of Bothnia, and they also raised Finnish morale.

During the early fighting the Finns developed their celebrated *motti* (literally, a bundle of sticks) tactics. The *mottis* were small, tight encirclements suited to the heavily forested Finnish terrain. In one of the later battles the personnel of a single Soviet division was trapped in 10 separate *mottis*.

The Finnish divisions on the Karelian Isthmus fought a delaying action in early December, withstood a full-scale assault on their main defense line at mid-month, and on December 23 counterattacked. The counterattack failed to gain much ground, but it took the Soviet command by surprise, and during the entire next month the fighting on the isthmus subsided into positional warfare.

In January 1940, Marshal Kliment Y. Voroshilov assumed over-all command, and Timoshenko took command on the isthmus, where the Thirteenth Army had been moved in on the right of the Seventh Army. The Soviet setbacks had resulted from a combination of supply problems, a winter of record cold, rigid and unimaginative leadership, and a lack of coordination between the various services. Mannerheim described the So-

viet attacks in December as similar to a performance by a badly directed orchestra. In January, the Soviet High Command pulled out units and retrained them immediately behind the front.

On February 1, the Russians opened their final offensive on the Karelian Isthmus. By that time, Soviet propaganda had inflated the Mannerheim Line into something like a super-Maginot Line. The offensive made steady if not rapid progress. On March 4, Soviet units on the west side of the isthmus began attacking across Viipuri (Vyborg) Bay, where the ice had frozen thickly enough to carry tanks. A few miles farther, and the Russians would have reached the open country north of the isthmus. On March 6, the Finnish government sent a deputation to Moscow, and on March 12 the Treaty of Moscow was signed, ending the war. The Finnish Army was still holding well, but, since it had suffered casualties of 24,923 killed and missing and 43,557 wounded, lacked manpower to continue much longer. The Russians probably lost about 200,000 men killed in battle or by the cold.

The terms of the treaty were onerous. Finland was forced to cede the Karelian Isthmus, including Viipuri and a strip of territory northeast of Lake Ladoga, the islands in the Gulf of Finland, the western half of the Rybachi Peninsula, and territory around Salla (now Kuolayarvi) and Kuusamo. The Soviet Union also acquired a 30-year lease on Hangö for use as a naval base. Finland lost its most defensible territory and had to absorb 400,000 refugees into an already badly shaken economy.

NORWAY AND DENMARK

German Planning.—When the campaign in Poland ended, the Germans, contrary to widely held opinion at the time, did not have a clear idea of what to do next. In a conference held on Sept. 23, 1939, Hitler raised the question of measures to be adopted "in case" the war against Great Britain and France had to be fought to a finish. The possibility of unrestricted submarine warfare, to be proclaimed as a "siege of Britain," was considered.

If Hitler had decided on the siege of Britain, it would have had to be executed by the German Navy and Air Force. On October 3, the commander in chief of the navy, Grand Admiral Erich Raeder, told his staff that he believed the navy could operate more effectively against the British Isles if it were to acquire one or two bases in Norway, possibly at Trondheim and Narvik. His thinking reflected the opinion, common in German naval circles after World War I, that the German Navy would have made a better showing in that conflict if, instead of being bottled up in the North Sea, it had had Norwegian bases to use as sally ports on the Atlantic. When it investigated the question of Norwegian bases on Raeder's orders, the Naval Staff learned that the chief of the Army General Staff, Col. Gen. Franz Halder, was pessimistic. He did not think that the army could either take or defend bases in Norway. The Naval Staff itself concluded that it was to Germany's advantage to keep Norway neutral, especially since the navy lacked sufficient ships to use the proposed bases for full-scale sea warfare. By taking the bases, it decided, Germany might lose more than she gained. While Norway remained neutral, its territorial waters afforded safe routes

German soldiers pass through a burning village during their invasion of Norway in April 1940.

Wide World

for German blockade-runners and for ships bringing Swedish iron ore down from Narvik. The German war industry was completely dependent on Swedish ore, which in winter, when the Baltic Sea froze, could be shipped only via Narvik.

During October and November, Hitler devoted all of his attention to plans for invading France and Belgium. Raeder tried to interest him in the Norwegian bases but failed until December, when he persuaded Hitler to grant an interview to Vidkun Quisling, who led a Norwegian copy of the Nazi Party. Quisling claimed to know that the Norwegian government had secretly agreed not to oppose a British invasion. After talking to Quisling, Hitler, on December 14, ordered the OKW Operations Staff to investigate the possibility of occupying Norway.

That Hitler began to think about Norway was not entirely Quisling's work. Soviet aggression against Finland had aroused strong sympathy for the Finns and had unleashed a wave of anti-German sentiment in Scandinavia. While Germany took a neutral stand that favored the Soviet Union, the Allies had begun talking about sending troops to help the Finns. If troops were sent, the shortest route would be through Narvik and across northern Sweden, directly past the Kiruna-Gällivare ore fields so important to Germany.

In January 1940, the Foreign Political Office of the Nazi Party undertook to maintain contact with Quisling and provide financial support for his party. Ignoring Quisling, OKW continued its planning on a small scale and in secret. Hitler did not show any real enthusiasm for the Norwegian venture until after February 16. On that day the British destroyer *Cossack* entered Norwegian territorial waters and took 300 captured British seamen from the German tanker *Altmark*. The *Altmark* had been the supply ship for the ill-fated commerce raider *Admiral Graf Spee*. Hitler became convinced that the British no longer intended to respect Norway's neutrality. On February 21, he called in Gen. (later Col. Gen.) Nikolaus von Falkenhorst, commanding general of the 21st Corps, and gave him the mission of planning and (if it were to be executed) commanding an operation against Norway.

Signs that the British and French intended to use the Russo-Finnish War as an excuse to intervene in Scandinavia added urgency to German planning in late February and early March. On March 7, Hitler assigned 8 infantry divisions and a motorized brigade to Falkenhorst. Toward the middle of the month radio intercepts indicated that troop transports were loading in British ports.

Another intercept, on March 15, revealed that the Soviet-Finnish armistice had spoiled the Allied plans. The armistice also deprived Hitler of his excuse for moving against Norway, and some of the officers in the planning group began to doubt whether it was worthwhile to go ahead. On March 26, however, Raeder told Hitler that, although Allied landings need not be expected in Norway in the near future, Germany would have to face the question sooner or later. He advised that Germany act as soon as possible, because the nights in northern latitudes would be too short to afford good cover for naval forces after April 15. Hitler agreed. On April 2, after reviewing the plans and learning from the air force and navy that the weather would be satisfactory, he named April 9 as the day for the landings.

Allied Intentions.—A British-French staff paper of April 1939 on strategic policy recognized that in the first phase of a war with Germany economic warfare would be the only effective Allied offensive weapon. In the light of this fact and of World War I experience in blockading Germany, Norway inevitably assumed a special importance for the Western powers as soon as war broke out. Before mid-September, the British government had made its first attempt to secure from Norway a "sympathetic" interpretation of its rights as a neutral.

The Soviet attack on Finland at the end of November aroused the hope that Norway and Sweden, motivated by sympathy for Finland and by their duty as members of the League of Nations, might permit Allied troops sent to aid the Finns to cross their territory. Such an undertaking could be made to include the occupation of Narvik and of the Swedish ore fields almost automatically. After Field Marshal Mannerheim appealed for aid on Jan. 29, 1940, the Allied Supreme War Council decided to send an expedition timed for mid-March. The plan, while ostensibly intended to bring Allied troops to the Finnish front, placed its emphasis on Norway and Sweden. The main force was to land at Narvik and advance along the ore railroad to its eastern terminus at Luleå, Sweden. Only after two brigades were firmly established along that line would a third brigade be sent into Finland. The preparations moved slowly, and the two governments never quite faced the question what they would do if Norway and Sweden refused transit rights or decided to fight. After Finland accepted the Treaty of Moscow on March 12, the whole project collapsed.

On March 21, Paul Reynaud became the head

Map 4. CONQUEST OF DENMARK AND NORWAY (April 9–June 9, 1940). To circumvent a suspected Allied occupation of Norway and to obtain naval and air bases on the open seas, Adolf Hitler decided to occupy Norway. German forces, landed by air and by sea, quickly gained virtual control of the country. Denmark, in the path of the invasion, succumbed without opposition. Anglo-French relief forces, landed in central Norway in mid-April, were soon forced to withdraw by constant German air and ground attacks. Those forces landed at Narvik were evacuated early in June as the Allied front in western Europe collapsed. The German Navy suffered serious losses, but later German submarines and aircraft based in Norway were to exact a frightful toll from Allied convoys attempting to bring much-needed supplies to the Russians at Murmansk.

of a French government committed to a more aggressive policy, and a week later the Supreme War Council again raised the Scandinavian question. A new plan called for two related operations: the laying of minefields in Norwegian waters; and landings at Narvik, Trondheim, Bergen, and Stavanger, to be justified by the expected violent German reaction to the minelaying. After some delays the mines were laid on the morning of April 8, but by then the German Fleet was already advancing up the Norwegian coast.

German Landings.—The initial German invasion force for Norway totaled 10,500 men. Provisions were made to introduce an additional 18,700 men through Oslo in the first week and 40,000 more thereafter. The plan called for a peaceful occupation of the country, allegedly to protect Norwegian neutrality. Falkenhorst's staff concluded that landings at Narvik, Trondheim, Bergen, Stavanger, Kristiansand, Egersund, Arendal, and Oslo would place the major centers of population in German hands and effectively crush

Norwegian attempts to mobilize. The earlier planners had considered that it would be sufficient to extract several bases from Denmark by diplomatic pressure, but Falkenhorst decided that it would be safer to take military possession of the country as a land bridge to Norway. To this task he assigned, under Gen. Leonhard Kaupisch, the headquarters of the 31st Corps, 2 infantry divisions, and a motorized brigade.

The first plans had called for an attempt to sneak troops into the Norwegian ports aboard merchant ships. Falkenhorst's staff considered this project too dangerous and decided instead to transport all of the landing teams (except the one for Stavanger, which was to go by air) in warships. Merchant ships were restricted to carrying supplies and troops for landings on the Danish islands, where they would not have to venture outside the German-controlled Baltic Sea. The decision to use warships made the landings the most hazardous phase of the operation: if the vastly superior British Fleet had put in an appearance, it might have destroyed virtually the whole German Navy.

The first two groups of warships sailed on April 7, escorted by the battle cruisers *Scharnhorst* and *Gneisenau*; 10 destroyers were bound for Narvik, and the cruiser *Hipper* and 4 destroyers for Trondheim. Nine other warship groups sailed at intervals that depended on their speeds and on the distances they had to travel. They consisted of the heavy cruiser *Blücher* and the pocket battleship *Lützow* bound for Oslo, several older cruisers, training ships, torpedo boats, and a variety of smaller craft carrying landing parties to Denmark. A British aircraft sighted the first two warship groups six hours after they sailed, but Admiral of the Fleet Sir Charles Forbes, commander in chief of the Home Fleet, concluded that the battleships, cruisers, and destroyers were setting out on a raiding mission into the Atlantic and sent his own ships steaming northward behind them, leaving the North Sea open for the remaining German warship groups.

The landings were executed on time on April 9 everywhere except at Oslo. There the old guns (Krupp model 1905) of the Oscarsborg fort 18 miles south of the city sank the *Blücher* and held the rest of the ships off until the following day. The delay gave the Norwegian king, Haakon VII, and the government time to escape from the capital and made conclusive the failure of the plan to occupy the country without a fight.

In the case of Denmark everything went exactly according to plan. On April 9, one division and the motorized brigade advanced northward across the border into Jutland (Jylland), and the other division staged landings on the islands. Early the same morning, the German minister, Dr. Cecil von Renthe-Fink, presented himself at the Foreign Ministry in Copenhagen (København) with a demand for surrender and assurances that the country would be permitted to retain much of its internal sovereignty. After he added that planes were on their way to bomb the city, the Danish government capitulated at 7:20 A.M.

In executing the Norwegian landings, the German surface fleet achieved its greatest success of the war. It also suffered near-crippling losses. The cruisers *Königsberg* and *Karlsruhe* were sunk before they could leave Norwegian waters, and in two battles (April 10 and 13) British ships sank the 10 destroyers which had taken troops to Narvik.

Norwegian Campaign.—On the morning of April 9, Norwegian Foreign Minister Halvdan Koht told Dr. Curt Bräuer, the German minister in Oslo: "We will not submit. The battle is already in progress." But how to fight was another matter. The Norwegian Army's total strength was 15,320 men, and half of them were stationed in the Arctic as an aftermath of the Russo-Finnish War. On April 9, the Germans captured a good share of the army's equipment and all the key communications centers. Two days later, from his headquarters at Rena north of Oslo, the Norwegian Army's commander in chief, Gen. Otto Ruge, had effective control of only one division. With that he planned to delay the German advance north from Oslo and hold open a field of operations in the interior for an anticipated Allied expeditionary force.

The first problem for the Germans was to establish land contact between Oslo and the landing parties in the other coastal cities. By April 16, Falkenhorst had units advancing northward toward Trondheim through the two great valleys, the Gudbrandsdal and the Østerdal. Between April 18 and 23, two British brigades, totaling about 6,000 men, landed at Åndalsnes south of Trondheim. Another 6,000 British and French troops went ashore at Namsos to the north of the city. At Tretten on April 23, the Germans defeated one British brigade which had advanced southward into the Gudbrandsdal from Åndalsnes, and thereafter the British withdrew to Åndalsnes, where their last troops were evacuated on May 2. The German units coming from Oslo had made contact with their Trondheim detachment the day before. In the meantime, the British and French had decided also to evacuate Namsos, which they did on May 3. The last Norwegian resistance in the area south of Trondheim ended on the same day, when the 2d Division surrendered on the Dovrefjell.

At Narvik events at first took a different course. The city could not be reached by land except through Sweden, and it was not within easy range for the Luftwaffe. The German commander in Narvik, Gen. (later Col. Gen.) Eduard Dietl, had 2,000 mountain troops and 2,600 sailors, survivors from the sunken destroyers. Beginning on April 14, British and French troops joined the Norwegian 6th Division in a seven weeks' siege that eventually drove the Germans out of Narvik and back to the Swedish border. By the last week in May, Dietl's force faced 24,500 Allied troops, but by then the British and French armies in France were collapsing, and the Allied command had decided to withdraw from Norway. After destroying the port installations at Narvik, the Allied troops began boarding ship on June 4, and the rear guard sailed on June 8.

On June 9, the Norwegian Army command agreed to an armistice, which ended the campaign at midnight that day. Although Norway was not again a scene of active operations, except for Commando-style raids and resistance activity, it remained in the forefront of the war until May 1945. Hitler regarded it as the northern bastion of his Fortress Europe and maintained a 300,000-man army there throughout the war.

4. Fall of the Low Countries and France

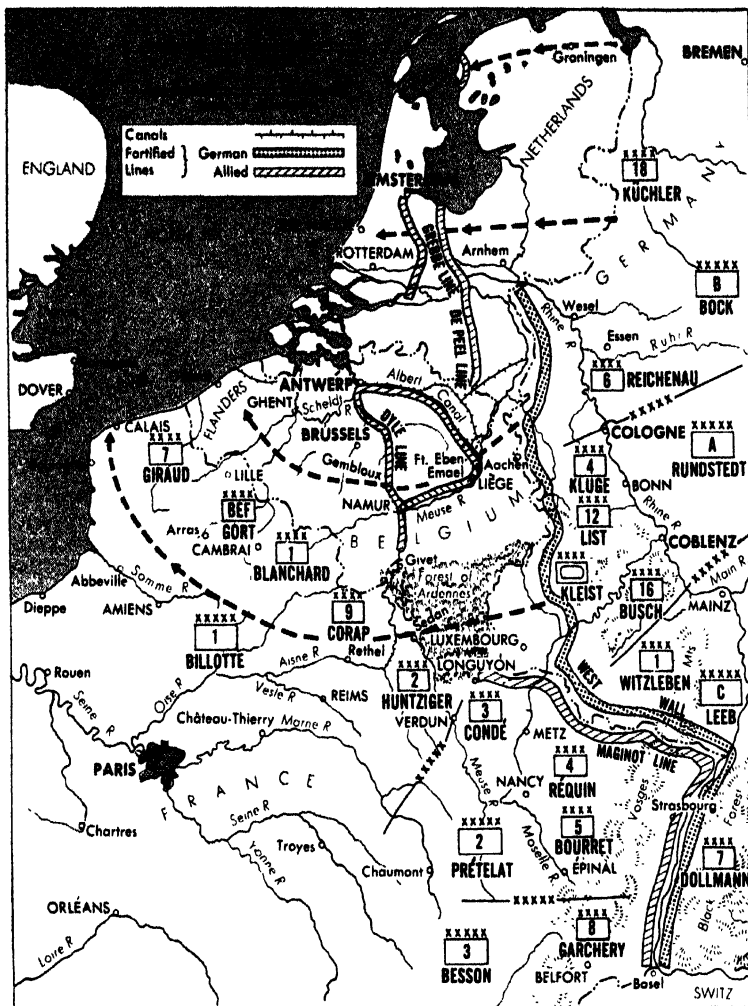

In October 1939, accepting the fact that the conquest of Poland, however impressive, would not prompt Great Britain and France to withdraw from the war, Adolf Hitler directed the High Command of the Armed Forces (*Oberkommando der Wehrmacht* or OKW) to prepare for an offensive in the west. Although the leading German commanders believed the better course to be to await an Allied offensive, he insisted on striking within six weeks in order to forestall further Allied preparations. The first version of the plan for the attack, called *Fall Gelb* (Plan Yellow), was modeled on the old Schlieffen Plan, which had received a modified test in 1914. It was based on a main effort through Belgium north of Liège. A total of 37 divisions was to make this effort, while a subsidiary force of 27 divisions moved through the Ardennes region of Belgium and Luxembourg.

This was exactly what the Allied commanders expected. An attack against northeastern France was improbable because of the existence of the Maginot Line, the formidable belt of fortifications built in the 1930's from Switzerland to Longuyon, near the junction of the borders of Belgium, Luxembourg, and France. Because of the barrier of the hilly, forested Ardennes, Allied commanders considered a major attack there also improbable. Thus only the Liège area, leading to the flatlands of Flanders and thence to France's northern frontier, was supposedly open to the Germans.

Though built originally merely to protect Alsace and Lorraine until France could mobilize against a surprise attack, the Maginot Line had engendered a false sense of security in the war-weary country. French commanders were nevertheless conscious of the great gap reaching from the end of the line to the English Channel. They accepted the fact of the gap on the theory that France could not afford to fight along this line. In the first place, battle in the industrial Lille-Cambrai region would destroy or deny two thirds of the nation's coal resources. Secondly, accepting battle there would mean acquiescence in the surrender of Belgium. This France, victor over Germany in World War I and still a major power with reputedly the world's strongest army, could not accept.

It was apparent to French and British leaders that once the Germans attacked, the Allies had to move into Belgium. To provide time for this movement the Allied leaders depended on a delaying action by the Belgian Army, reinforced by the barrier of the Ardennes and the Meuse River, the large forts at Liège, the deep cut of the Albert Canal north of that city, and Fort Eben-Emael near the Dutch-Belgian border. (This fort was said to be the strongest single fortress in the world.) The major problem was the lack of consultation and coordination with the Belgians and the Dutch. Although the Low Countries realized that Nazi Germany would include them in any pattern of conquest against the West, they continued to hope that a policy of abject neutrality would forestall the inevitable.

The Allies planned nevertheless to advance

Map 5. GERMAN PLAN FOR THE INVASION OF FRANCE AND THE LOW COUNTRIES (May 10, 1940). The Allies expected the coming German offensive to follow the same sweeping path through the Low Countries that the German invasion of 1914 had taken. Accordingly, it was their plan to move into Belgium at the opening of hostilities to reinforce the Belgians at the Dyle Line, and there to stop the German invasion. This time, however, the Germans planned to make their main effort through the difficult but lightly guarded Ardennes area, driving quickly to the English Channel ports, and thus to split the Allied armies and isolate those in the north.

into Belgium to the line of the Scheldt (Escaut, Schelde) River (Plan E). As the months passed without a German attack and the British Expeditionary Force (BEF) was increased to 10 divisions, this plan was replaced by a more ambitious decision to move to the Dyle River, a few miles east of Brussels (Bruxelles). Under Plan D, as the new concept was called, the Belgian Army was to fall back on the Dyle and the lower reaches of the Albert Canal to protect Antwerp (Antwerpen), the British were to defend the upper Dyle, and the French were to hold the Gembloux gap between the Dyle and the Meuse at Namur (Namen) and the Meuse itself where the river crosses the Ardennes. In the continued belief that the main German effort would be made in the Liège area, the supreme French commander, Gen. Maurice Gustave Gamelin, assigned to the Gembloux gap his strongest force, the mechanized First Army under Gen. Georges M. J. Blanchard. The second strongest force, the Seventh Army under Gen. Henri Giraud, ostensibly a reserve, was to move swiftly into the southern Netherlands to assist the Dutch. In keeping with the theory that the Ardennes itself was a considerable barrier, a weaker force, the Ninth Army under Gen. André Georges Corap, was to defend the Meuse from Namur to Sedan;

and another weak force, the Second Army under Gen. Charles Huntziger, was to serve both as a bridge between Sedan and the garrison of the Maginot Line and as a hinge for the wide-swinging movement of the Allied armies into Belgium.

As the Germans prepared for attack in November 1939, an invasion scare gripped the Allies, but bad weather forced postponement of the attack. After repeated postponements because of weather conditions, the attack was firmly scheduled for Jan. 17, 1940. A week before the target date, however, a German plane strayed off its course and was forced down in Belgium. On the two officers aboard the Belgians found orders for the air phase of the invasion. This prompted an alarm of even greater proportions than before, and some French forces began moving toward their assigned sectors along the Belgian border. German observers could not help but note the nature of the French deployment, particularly the weakness of the armies at the hinge near Sedan. Of even greater consequence was the fact that the information gained from the fliers confirmed General Gamelin's view that the invasion was to come through the Liège area and not through the Ardennes.

In the meantime, Hitler and several of his subordinates had begun to question the basic

concept of Plan Yellow. Indeed, even before the November target date, Hitler himself had forced change in plan that shifted the main effort from north of Liège to both sides of the city. Col. Gen. (later Field Marshal) Gerd von Rundstedt, commander of Army Group A, which was to drive through the Ardennes, insisted that the main effort be made through that sector with armored divisions to the fore. In an audience with the German leader, Rundstedt's chief of staff, Lt. Gen. (later Field Marshal) Erich von Manstein, apparently provided the final arguments needed to change Hitler's mind. After weather again forced the cancellation of the target date, Hitler postponed the offensive until spring and ordered a basic alteration in the plan. Army Group B, in the north, commanded by Col. Gen. Fedor von Bock, was reduced to 28 divisions, only 3 of which were armored. Rundstedt and Army Group A in the Ardennes had 44, including 7 armored divisions. With the main thrust moving in Sedan, Rundstedt was to drive to the channel, trapping French, British, and Belgian armies in Belgium.

Meanwhile, the Allies failed to profit materially from the eight months' respite that they had gained between the declaration of war and the onset of major hostilities in the west. They still felt no real sense of crisis, for they continued to consider the speed of the Polish campaign attributable less to German strength and to a new mode of warfare than to Polish weakness. Although some effort was made to extend the Maginot Line fortifications to the coast, it produced little more than a shallow antitank ditch and a few widely spaced blockhouses. Modern equipment for the French armies and the BEF remained a promise rather than a reality. Allied timetables for troop movements still resembled those of World War I. Corap's Ninth Army, for example, planned on five days for the move to the Meuse covering the Ardennes while only cavalry units sought to delay the Germans east of the river. The Allies, and particularly the French, still looked on tanks as servants of the infantry, wheeling them out to infantry divisions rather than massing them in hard-hitting armored formations in close liaison with tactical aircraft.

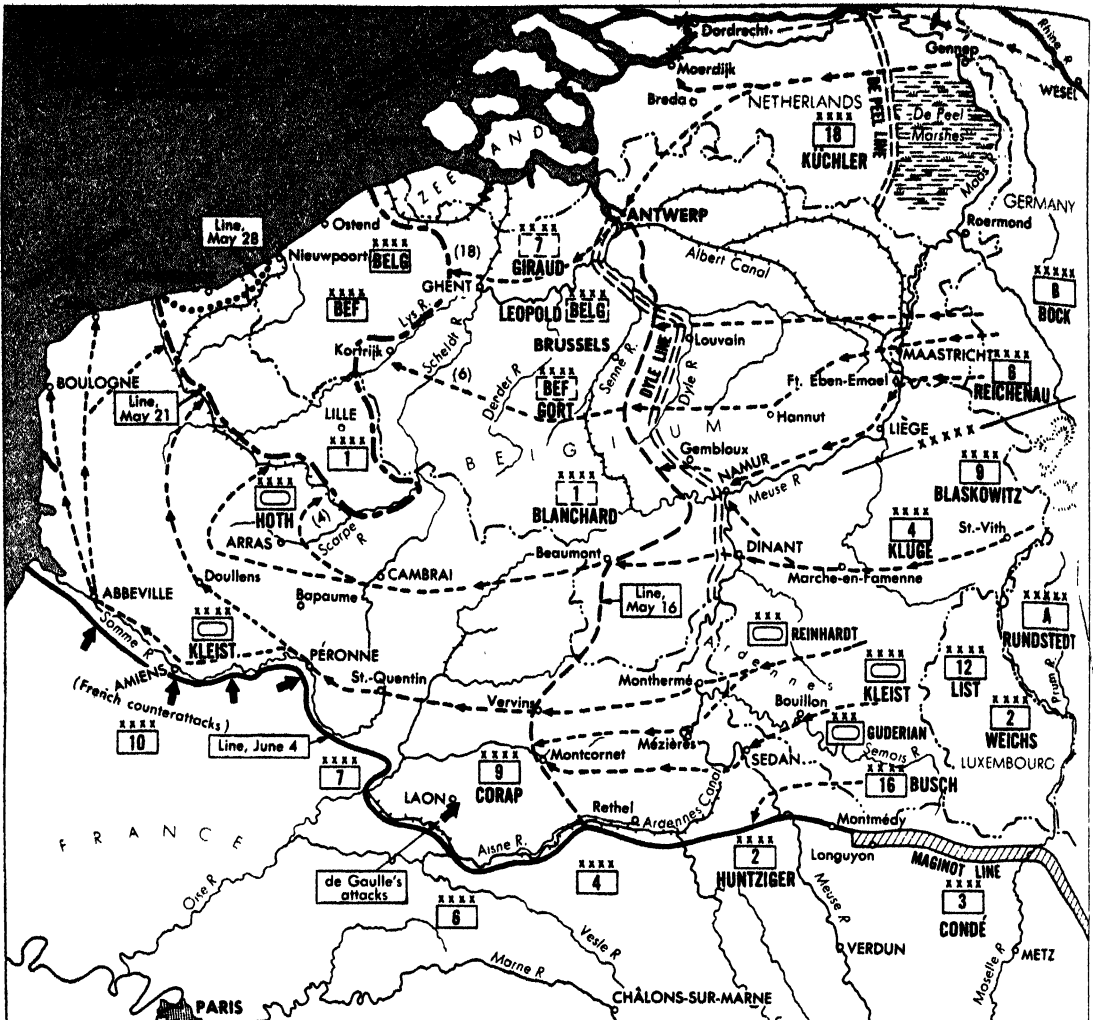

The Allies actually were superior numerically to the Germans. The French, Dutch, Belgians, and British together had approximately 4,000,000 men available, in contrast to about 2,000,000 Germans who might be used against them. As of May 1940, 136 German divisions were in the west, as opposed to 94 French divisions in northwestern and northern France, plus 10 British, 22 Belgian, and 9 Dutch divisions. In tanks, too, the opposing forces were relatively equal. The Germans had 2,439 tanks in the west; the Allies, 2,689. Nor were German tanks vastly superior except in speed. Created as infantry support weapons, French tanks were heavily armed and armored but lacked appreciable speed and cruising range. In aircraft the Germans enjoyed some advantage in over-all numbers, with about 3,200 planes to 1,200 French and 600 British planes, but in fighter aircraft alone the two forces were approximately equal. Only in antiaircraft and antitank weapons were the French markedly inferior. The difference in opposing forces thus was less a question of numbers and quality than of a variance in approach to modern warfare. The Germans had developed new methods based on quick breakthroughs by armor supported by

mobile artillery and aircraft, followed by rapid exploitation of the resulting gaps. In addition, a kind of war-weary lethargy still gripped both France and Britain, as is evidenced by their relatively slow industrial mobilization. Not until Hitler invaded Denmark and Norway in April 1940 was the full portent of the Nazi threat accepted in the two nations. By that time it was too late.

Defeat of the Netherlands.—It took the Germans only five days to defeat the Dutch Army, a force of about 400,000 men under Lt. Gen. Henri Gerard Winkelman. Before daylight on May 10, parachutists landed near Rotterdam and The Hague. They captured bridges vital to Dutch defensive plans and airfields where reinforcements could be landed from transport planes soon after daylight. There and elsewhere a sizable body of fifth columnists (German nationals or Dutch Nazi sympathizers) aided the invaders. By this daring, revolutionary strike from the air, the Germans in the first blow had pierced the perimeter of the final Dutch defense line, the so-called Fortress of Holland protecting Rotterdam and The Hague. The German Eighteenth Army, led by Gen. (later Field Marshal) Georg von Küchler of Bock's Army Group B, launched the ground attack at dawn, the main column striking through the southern Netherlands to envelop the Dutch south flank. This column captured a railroad bridge across the Maas (Meuse) River intact, forcing the Dutch to relinquish their first line of defense along the river that night.

Beset by German planes, advance guards of the French Seventh Army reached Breda on the second day, May 11, there to try to hold with the Dutch forces that had fallen back from the Maas. Two days later, however, on May 13, the French were forced to retreat toward Antwerp. Meanwhile a German armored division made contact with the airborne troops near Rotterdam. While Queen Wilhelmina and the Dutch government left for England, the remainder of the Dutch Army withdrew into the Fortress of Holland. On the morning of May 14, the Germans warned that if resistance continued, Rotterdam and Utrecht would be destroyed from the air. Two hours before the ultimatum was to expire, the Luftwaffe leveled the business section of Rotterdam, inflicting 30,000 civilian casualties. With the tiny Dutch Air Force wiped out, the nation's final defensive line already breached, and no hope of Allied aid from any source, General Winkelman surrendered late on May 14.

Onslaught in Belgium.—Elsewhere in Bock's Army Group B, the Sixth Army under Gen. (later Field Marshal) Walter von Reichenau attacked just before dawn on May 10 to jump the Meuse and the Albert Canal north of Liège and swing southwestward into the Gembloux gap. Taking out the guns of Fort Eben-Emael was essential to the army's progress. In a minutely planned operation, German parachutists and glider troops landed within the fortress and quickly seized key points. The garrison was forced to surrender around noon on the second day, May 11. The line of the Meuse and the Albert thus compromised, the Belgians began to fall back to the Dyle that night under cover of advance contingents of British and French troops. Meanwhile, strong German units advanced on Liège. They occupied the city on May 12, but although they seized a number of the big forts, others held out, the last falling on May 29, though without

Map 6. GERMAN INVASION OF FRANCE AND THE LOW COUNTRIES (May 10–June 4, 1940). The German offensive was conducted as planned and proved surprisingly effective. Though hindered somewhat by the difficult terrain in the Ardennes, German armored forces finally broke through and raced for the Channel coast. With their forces in movement into Belgium and without knowledge of the speed and power of the new blitzkrieg, the Allies could not muster major resistance to the armored thrusts. Such minor counterattacks as could be organized and launched were futile. In less than two weeks, Adolf Hitler's armored forces had reached the coast. There they halted, allowing most of the British and many French troops to be evacuated to England from their entrapment at Dunkerque. By early June, the Germans were prepared for a thrust southward from the Somme-Aisne river line to complete the subjugation of France.

influencing the general course of the campaign.

By May 15, the Sixth Army had been built up against the Dyle Line, while the main column of the Eighteenth Army in the Netherlands swung southwestward against the Belgian left flank near Antwerp. Although the French First Army fought valiantly in the Gembloux gap, by the morning of May 16 French armor had incurred disturbing losses. So strong was the Sixth Army's onslaught against the Dyle Line that the Allies had considerable justification for continuing to believe that the main German effort was in the north. But it would now be only a question of time before Rundstedt's Army Group A, its panzer columns shielded at first by the forests and valleys of the Ardennes, made its full weight felt in the south.

Army Group A controlled six armies, three in line and three in reserve. The northernmost army,

the Fourth under Gen. (later Field Marshal) Hans Günther von Kluge, pointed an armored corps at Dinant. In the center an armored force called Panzer Group Kleist after its commander, Gen. (later Field Marshal) Ewald von Kleist, was the equivalent of an army with two armored corps and a follow-up corps of 5 motorized divisions. The corps in the north under Gen. Hans Reinhardt had 2 armored divisions aimed at the Meuse around Monthermé; the other, with 3 armored divisions under Gen. (later Col. Gen.) Heinz Guderian, was aimed at Sedan. South of Panzer Group Kleist the Sixteenth Army under Gen. (later Field Marshal) Ernst Busch was to cover Kleist's south flank east of the Meuse. Once Kleist achieved his penetrations, three other armies were to move forward to protect the south flank of the drive to the sea.

On the French side the error of the high com-

mand in placing two mediocre armies in the Ardennes sector against what was to be the main German effort was compounded by the dispositions ordered by the army commanders. General Huntziger (Second Army) put his strongest divisions in the Maginot Line; his weakest (newly mobilized reservists), along his left boundary near Sedan. General Corap (Ninth Army) put his two weakest divisions along his right boundary near that city. Thus the main German thrust of Kleist's armor was destined to strike not only the two weakest French armies but their weakest portions as well.

As Rundstedt and his subordinate commanders learned on May 10, there was some reason for the French theory that the Ardennes is a difficult barrier for major attacks. It took all of the first day for the armor to cross the undefended northern portion of Luxembourg. Yet on the second day the columns picked up momentum, and the cavalry of the Belgian *Chasseurs Ardennais* and of Corap's Ninth Army could do little to stay the German tanks. French aircraft were absent, preoccupied with the presumed main effort in the Gembloux gap. By nightfall of May 11, Guderian's columns had reached Bouillon, on the serpentine Semois River only a few miles from Sedan. Although a blown bridge forestalled further advance for the night, the armored corps forced a crossing early the next day, and by nightfall it overlooked the great loop in the Meuse at Sedan that had played a vital role in the defeat there in 1870 of the army of Napoleon III. Meanwhile, Reinhardt's armor reached the Meuse near Monthermé and Mézières, north of Sedan. Although both Reinhardt and Guderian prepared to cross the Meuse on May 13, the honor of the first bridgehead fell to the 7th Panzer Division of the Fourth Army, under the command of Gen. (later Field Marshal) Erwin Rommel. A column of the division reached the Meuse at Dinant on the evening of May 12, narrowly missed taking a railroad bridge intact, and then sent a patrol across during the night over an old dam or weir. Under concealment of a fog soon after daylight on May 13, reinforcements crossed in rubber assault boats. Night fell with Rommel holding a bridgehead a mile deep.

Neither Guderian nor Reinhardt had yet built up sizable forces for an assault crossing of the Meuse near Sedan, but an attack was ordered for the afternoon of May 13 in the hope of catching the French before they were prepared for it. To compensate for the absence of heavy artillery, hundreds of fighters and Stuka dive bombers began to bomb and strafe French positions four hours before the assault began. Confronted with this terrifying new departure in warfare, some of the defending French reservists panicked. Nevertheless, the French made their enemy pay dearly in the actual assault. Artillery and machine guns cut down half of the German troops, but the other half got across the river. Three out of four attempted crossings succeeded, and by midnight a pontoon bridge spanned the Meuse. The next day, May 14, General Huntziger hastily counterattacked Guderian's south flank with a cavalry division, though without appreciable success. Guderian's 2d Panzer Division plunged on to the west, seizing two bridges intact across the Ardennes Canal. The spectacular drive from the Meuse to the Channel coast had begun.

In the meantime, Reinhardt's armored corps had greater difficulty. French artillery and small-

arms fire beat back two crossing attempts at Mézières and Monthermé. Not until almost nightfall, after tanks had arrived to deliver point-blank fire across the river, was a crossing achieved, and then only at heavy cost. All through the next day, May 14, the status of the bridgehead remained in doubt as the French mustered local reserves against it, but by the morning of May 15 Reinhardt's engineers had put in a pontoon bridge, and reinforcements poured across it. The French fallacy in failing to establish defenses in depth then became painfully apparent: by evening advance contingents of Reinhardt's armor were 35 miles beyond the Meuse, close to Guderian's flank. Army Group A had made a gap 50 miles wide in Second and Ninth Army positions. The breakthrough was complete.

Drive to the Channel.—The breakthrough in the south seriously jeopardized the main Allied forces in Belgium. The French Seventh Army on the extreme left had already lost some of its advance contingents in the Netherlands, and others retreated to the island of Walcheren between Antwerp and the sea (there to hold until May 17), while late on May 14 what remained of the army began to move southward under orders from General Gamelin to try to reinforce Corap's Ninth Army. The next day, Gamelin replaced Corap with the Seventh Army commander, Giraud. Meanwhile, the Belgians and the British were not particularly hard pressed in their positions behind the Dyle, and the French First Army at a continuing heavy cost in casualties maintained its positions in the Gembloux gap. In view of the breakthrough to the south, however, none of this mattered much. In midmorning of May 16, Gen. Gaston Henri Billotte, the army group commander in Belgium, ordered a withdrawal to the Scheldt River, the line originally contemplated in Plan E.

In the meantime, the French High Command had tried to muster reserves to eliminate the armored penetration near Sedan. There was a frenzy of improvisation—a division ordered here, another there, 7 divisions pulled out of the Maginot Line, the Second Army ordered to attack northward, the First Army ordered to attack southward—but none of it bore directly on the realities of the situation. In almost every case the scheduled times of counterattack showed that the French generals still failed to appreciate the speed of the new type of warfare. The only two counterattacks of any consequence were launched northeast of Laon by a newly created armored division, the 4th, under a general of brigade, Charles de Gaulle, who in the 1930's had raised one of the few voices urging French adaptation to the methods of armored warfare. Although de Gaulle gained initial successes on May 17 and May 19, he could not hold the positions he won without help.

Moving with impressive speed, Kleist's armor on May 18 took St.-Quentin, halfway to the Channel from Sedan, and by the end of the day had reached Péronne. The next day the tanks reached Amiens and Doullens, 40 miles from the coast. On May 20, Abbeville fell, and for all practical purposes German armor faced the Channel. The British line of communications, which had been based on Cherbourg and the Brittany ports in deference to German strength in the air, was severed. In 11 days the Germans had driven from the eastern frontier of Luxem-

bourg to the coast, a distance of more than 240 miles.

Allied attempts to stem the onrush north of the German penetration were almost as futile as the French efforts from the south. Although the BEF withdrew in good order to the Scheldt, arriving at the river during the night of May 18, the situation on both flanks had begun to disintegrate. Kùchler's Eighteenth Army hammered the Belgians in front of Antwerp relentlessly and took the city on May 18. By May 21, the Belgians were back on the Lys River protecting Ghent (Gent). Although the French First Army held a salient extending southeast of Lille, the fact that the Ninth Army had collapsed (the new commander, Giraud, was captured on May 18) left the French right flank and thus the British rear unprotected. The next day the BEF commander, the 6th Viscount Gort, created two makeshift commands, each somewhat larger than a brigade, as a first step in forming a so-called canal line from the Channel near Dunkerque to the vicinity of Arras.

Short of an attempt to withdraw across the Channel, the only hope for the Allies appeared to lie in cutting the German penetration and thereby establishing a firm line from the Somme to the Scheldt. This General Camelin ordered late on May 19, only a short while before the French government relieved him of command. The new supreme commander, Gen. Maxime Weygand, canceled the order pending consultation with the commanders in the pocket. Flying to Calais on May 21, Weygand talked with King Leopold III of the Belgians and with General Billotte, the army group commander, but he failed to see Lord Gort, who was delayed en route to the meeting. After ordering a combined British-French attack toward Bapaume and Cambrai with 8 divisions, to be met by a French attack northward across the Somme, Weygand departed. While returning from the conference, Billotte was killed in an automobile accident. Although Weygand ordered General Blanchard to fill the post of group commander, Billotte's death combined with Camelin's relief and Weygand's delay to deprive the forces in the pocket of strong central command for three critical days when a coordinated counterattack to the south might have succeeded.

Under orders from his government, Lord Gort had already attempted one counterattack on May 21. With the promise of considerable help from the French First Army, he intended to

drive southward from Arras, but as the French assistance materialized, it amounted to only 60 tanks, and unremitting German pressure forced the diversion of a substantial part of the British troops. The counterattack failed even to reach the first day's objectives a few miles below Arras, and as night fell, Gort pulled the troops back to Arras and the canal line. The next day, May 22, as the First Army mustered 2 divisions to counterattack, Gort was too hard pressed on his two fronts, the positions on the Scheldt and the canal line, to give any help. Although the French divisions almost reached the outskirts of Cambrai, German dive bombers forced their withdrawal. The French in the south then mounted an attack on May 23, but it failed even to cross the Somme. For all practical purposes, this ended the efforts to link the troops in the pocket, which still totaled 40 divisions, with the main French armies in the south.

Retreat to Dunkerque.—With the collapse of these measures, the forces in the pocket appeared doomed. Boulogne was about to fall, and Calais was under siege, leaving Dunkerque (q.v.) as the only port. German armor had already forced one crossing of the canal line, and a rapid thrust to cut the Allied troops from the sea seemed likely. Then, abruptly, the German armor came to a halt. In later years some German commanders tried to place full responsibility for the decision to halt the armor on Hitler, but contemporary records appear to indicate that even if the decision was Hitler's, the impetus for it came from Rundstedt. By May 23, Rundstedt's tanks had incurred 50 percent losses, and the terrain beyond the canal line, crisscrossed by waterways and flooded lowlands, was unattractive for armor. Furthermore, heavy tank losses at this stage would seriously endanger the pending attack southward across the Somme into the heart of France. In the early evening of May 23, Rundstedt ordered his armor to halt, ostensibly to reorganize before moving against the canal line. The next morning, however, after a conference with Rundstedt, Hitler sanctioned stopping the armor altogether and leaving the mopping up to the infantry divisions.

At almost the same moment a new threat developed from another direction against the forces in the pocket. On either side of Kortrijk (Courtrai) on the Lys River, Bock's Army Group B opened a major attack against the Belgians. Despite help rushed by the British and the French, the Belgian Army began to give way

The Times, London

on May 26. Concluding that his forces were too depleted and embattled to break away for withdrawal to the Yser River, King Leopold on the next day sent an emissary to the Germans to ask the terms of an armistice. Though the terms were unconditional surrender, he deemed that he had no choice but to accept, and the army surrendered on May 28. Anticipating the Belgian collapse, the British government, in the early evening of May 26, had authorized Lord Gort to withdraw the BEF to England. The French Command authorized one of three French corps to participate in the withdrawal, but the other two corps of 6 divisions, closely engaged near Lille, fought on until they were surrounded, eventually surrendering on June 1.

The withdrawal to a shallow perimeter based on canal and river lines around Dunkerque began the night of May 27 and continued through the next day. The embarkation maneuver, called Operation Dynamo, began officially on May 27. A disappointing 7,669 men were embarked that day, but the tempo of the operation picked up thereafter. A total of 848 British, Dutch, Belgian, and French ships of all sizes from destroyers and Channel ferries to fishing smacks and private yachts plied the rough waters of the Channel under the cannon and bombs of the Luftwaffe and the guns of coastal batteries for eight days and nights. They removed from the harbor of Dunkerque and nearby beaches 338,226 men, two thirds of them British.

Fall of France.—While these dramatic events occurred in the north, the French south of the German penetration were attempting to build a new line generally along the Somme and Aisne

rivers. Known as the Weygand Line, the new positions emphasized defense in depth in the hope of sealing off German penetrations and permitting prompt local counterattacks. With his forces reduced by half, General Weygand concentrated his greatest strength in the coastal sector, where he expected the Germans to strike for the ports to deny aid from Britain, and on the plain of Champagne east of Reims, which

Map 7. FALL OF FRANCE (June 5-25, 1940). Gen. Maxime Weygand strove desperately to organize a defense behind the Somme and the Aisne, but he had insufficient forces to stem the overwhelming power of the German offensive. The crisis came on June 12, when Gen. Heinz Guderian's armor broke through the line at Châlons-sur-Marne and raced toward the Swiss border, which it reached on June 17, trapping the 500,000 Frenchmen in the Maginot Line. Thereafter, organized resistance collapsed. Paris fell on June 14; by June 25, the German advance had reached the line shown. Benito Mussolini had joined Adolf Hitler in the war on June 10, and pressed the French in the south. Fighting stopped on June 25, after the French had signed armistices with the Germans and the Italians.

offered ideal ground for tanks. He had correctly divined the German intentions, but the entire Somme portion of the new line was weak from the outset because of German bridgeheads established during the dash to the sea. On June 5 and June 6, Bock's Army Group B launched what was considered the secondary effort northwest of Paris. Although the French fought with bitter determination, fresh German units soon made the difference. By nightfall on June 8, Bock had achieved a decisive breakthrough. As the French northwest of Paris fell back, they compromised the left flank of the armies on the Aisne. Here, where Rundstedt's Army Group A launched the German main effort on June 9, gains for the first three days were meager, and even small gains came under immediate French counterattack. Then, on June 11, the French were forced to fall back behind the Marne in deference to their open flank. The next day, as four armored divisions under Guderian broke through, the fate of France was sealed.

Meanwhile, Benito Mussolini's Fascist Italy declared war on France and Great Britain on June 10. As the French government declared Paris an open city and withdrew, first to Tours and then to Bordeaux, the Germans entered the capital on June 14. On the same day, Army Group C, commanded by Gen. (later Field Marshal) Wilhelm von Leeb, began to attack the Maginot Line and achieved two quick penetrations against a garrison minus its mobile reserves. On June 17, Guderian's tanks reached the Swiss border, cutting off the 500,000 French still in the big forts.

As Premier Paul Reynaud considered the possibility of withdrawing the government to North Africa to continue the war, Prime Minister Winston Churchill encouraged him on June 16 with an offer of "indissoluble union" with Britain, but a majority of the cabinet voted to request armistice terms. On June 17, the aging World War I hero, Marshal Philippe Pétain, heading a new government, asked for an armistice. In the early minutes of June 25, the six-week ordeal ended. France lay prostrate, beaten in a 42-day campaign that stunned the world.

German casualties in the campaign were comparatively light, approximating 156,000, including 27,000 killed and 18,000 missing. The British incurred 68,000 casualties, plus the loss of almost all their weapons and equipment. The French have estimated that they lost 123,600 men killed, missing, and captured and 200,000 wounded. The Germans claimed 1,500,000 prisoners, a not unlikely figure in view of wholesale French surrenders between Pétain's request for an armistice and the final cease-fire.

Battle of Britain.—Britain stood alone, protected only by the Royal Navy, the moat of the Channel, an army almost devoid of guns, 59 Royal Air Force (RAF) fighter squadrons, and grim determination. While the German armies were defeating France, Hitler directed preliminary planning for the invasion of Britain (Operation Sea Lion). It soon became apparent that the defeat of the RAF was a vital preliminary to any invasion attempt. Although the Luftwaffe initiated strikes against coastal shipping early in July, it was the end of the month before the necessary bases could be built up in France and the Low Countries for the air offensive to begin in earnest. In an air battle that lasted until the end of October, the German object throughout

was to destroy RAF fighter strength, thus providing a free field for German bombers. To achieve this goal the Luftwaffe concentrated primarily against ports and shipping until August 12, and from August 13 to September 6 against airfields and aircraft factories.

As had been proved in the skies above Dunkerque, the British Spitfire fighters were superior to the German mainstay, the Messerschmitt 109, in maneuverability and armament and at least its equal in speed. Moreover, the Germans had to contend with the valor of British pilots and the efficiency of British radar and ground defenses. In the first phase of the battle, German fighters flew from 5,000 to 10,000 feet above their bombers; this enabled part of the RAF fighters to make a holding attack against the German fighters while the others struck at the bombers. In the second phase the Luftwaffe switched tactics to provide fighter cover at lower levels, but the British countered by intercepting the attackers farther out. In both phases the RAF inflicted disproportionately heavy losses on the Luftwaffe. On August 16, for example, the Germans lost 144 of 1,000 planes, while the British lost only 18. Unrealistic claims by Luftwaffe pilots soon confused the Luftwaffe command: on August 16, the pilots erroneously claimed 65 British planes. When this led to the inevitable assumption that the RAF's first line of defense had been broken, the Germans switched on September 7 to inland targets, including cities, in the hope of bringing to battle RAF reserves. Thus began the large-scale raids on cities like London and Coventry, which inflicted heavy damage and high civilian casualties but did little to change the ratio of British and German losses in planes.

By September 12, continued heavy air attacks and a concentration of barges in Belgian and French ports convinced many persons in Britain that invasion was imminent. Actually, no invasion was ever ordered or attempted. On September 17, Hitler tacitly admitted defeat in the Battle of Britain by postponing the invasion indefinitely. During the last week of September continued high German losses brought an end to large-scale daylight raids. As the Luftwaffe turned to night attacks, mainly against London, the battle took on the aspects of a siege. Although air attacks would continue through much of the war, the Battle of Britain per se was over by mid-October as Hitler turned his attention toward the Balkans and the Soviet Union.

In the Battle of Britain the RAF lost a total of 790 fighters; the Luftwaffe, 1,389 planes of all types. As an indication of the thin margin on which the RAF operated, there were only 570 Hurricanes and Spitfires on hand at the height of the battle. "Never in the field of human conflict," said Churchill, "was so much owed by so many to so few." Britain had stood alone, and Britain had won.

5. Recovery of France and Advance into Germany

PLANS FOR THE ALLIED INVASION OF FRANCE

Even though military resources in Britain were meager after the withdrawal from France in 1940, British forces soon began to plan a return to the Continent. In September 1941, the British Chiefs of Staff charged Adm. Lord Louis Mountbatten (later 1st Earl Mountbatten of Burma), who headed the Combined Operations Headquarters, with investigating the technical problems of amphibious operations. Not long afterward the British joint planners drew up the first formal plan for a cross-Channel attack. This plan, which was called Roundup, assumed a marked deterioration of German strength. Projecting the use of relatively small British forces, it was designed to disrupt German withdrawal to the homeland in the final phase of the war.

Though American military officers were in England as observers as early as October 1940, the World War II alliance between the English-speaking nations began to take definite shape only in January 1941. This was the month when American and British military officers met in Washington for conversations that became known as ABC-1. The agreements reached—that the two nations were to maintain joint planning staffs in

Map 8. THE ALLIES RETURN TO FRANCE (June 6, 1944). The map shows the concentration areas of the invasion forces in England, their organization for the invasion, the beaches at which the five assault forces were to land, and the air-borne operations to be conducted in support of the amphibious assaults.

Washington and London and that, if forced into war with both Japan and Germany, the United States would join Britain in defeating Germany first—started the chain of events that led to the eventual cross-Channel invasion and victory in Europe. It was two months later, in March, when Congress passed the Lend-Lease Act, which authorized the United States to provide war materials for nations under Axis attack. By June, with the American observers in London having become the Special Observer Group and the British having sent representatives to Washington, the two countries were in close liaison. Though the United States still was not at war, American troops replaced British troops in Iceland in July 1941, and later in the summer began to construct naval and air bases in the United Kingdom, ostensibly for British use.

Developing Alliance.—Immediately after the Japanese attack on Pearl Harbor and the German declaration of war against the United States, as American and British military leaders met in Washington in a series of conferences known as Arcadia (December 1941–January 1942), they reaffirmed the ABC-1 decision to remain on the strategic defensive in the Pacific while defeating Germany first. They decided to wear down German resistance in 1942 by air bombardment, by assisting the USSR, and by trying to gain the entire North African coast, before initiating in 1943 a large-scale land offensive against Germany across either the Mediterranean Sea or the English channel. They also created the Combined Chiefs of Staff (CCS), consisting of the United States Joint Chiefs of Staff and the British Chiefs of Staff, as the body to assist and advise President Franklin D. Roosevelt and Prime Minister Winston Churchill on the direction and conduct of the war. The most prominent members of the CCS were Gen. (later General of the Army) George C. Marshall, United States Army chief of staff, and Gen. (later Field Marshal) Sir Alan F. Brooke (later 1st Viscount Alanbrooke), chief of the Imperial General Staff. Because the CCS met only periodically, the American and British members did the detailed work of planning separately. Those most concerned with planning a European invasion were the Operations Division (OPD) of the United States War Department and the British Combined Commanders (the senior ground, naval, and air officers, together with Lord Mountbatten).

Differences between the Allies in general strategic outlook soon became apparent. The British, acutely conscious of the difficulty of a Channel crossing, aware of the need for special boats and equipment, and impressed by the strength of the German Army, favored a peripheral strategy, including ground operations in the Mediterranean or in Scandinavia and such indirect methods of attack as blockade, air bombardment, and the encouragement of subversive activities in German-occupied countries. Only when the Germans had been weakened to the point where an invasion would be sure of success was a cross-Channel attack to be launched. The Americans, more conscious of the needs of the Pacific war, and therefore impatient for victory in Europe, rejected the peripheral areas for major operations, for they believed that only by a showdown in northwestern Europe could the Germans be beaten.

As the first American ground troops (34th Division) arrived in Northern Ireland in January

1942, the Special Observer Group was redesignated the United States Army Forces in the British Isles. Not long afterward, United States air force contingents began to arrive in England for eventual participation in the bombardment of German-held Europe, and in July American air crews in borrowed Royal Air Force (RAF) planes flew their first mission, a daylight attack against German airfields in the Netherlands. Then, in August, the Eighth Air Force, commanded by Maj. Gen. (later Gen.) Carl Spaatz, carried out the first bombing of Europe by American pilots flying American planes.

Because the Americans still were building up their strength and because British resources were hardly sufficient to carry out a cross-Channel attack alone, the British chiefs concluded that no cross-Channel operation was feasible in 1942 unless Germany showed unmistakable signs of collapse. Even 1943 remained doubtful. In March 1942, the OPD nevertheless began work on an outline plan for a full-scale invasion of Europe in 1943. The following month, General Marshall and Harry Hopkins, confidential adviser to President Roosevelt, went to London to try to gain British acceptance of the idea. The British agreed not only with the concept but also with a War Department proposal, code named Bolero, for a great buildup of American forces in Britain, with approximately 1 million men to be equipped and trained to carry out air operations in 1942 and a major invasion of the Continent in 1943. To implement the decision, Maj. Gen. (later Lt. Gen.) John C. H. Lee arrived in the United Kingdom in May to activate the Services of Supply. On June 24, Maj. Gen. (later General of the Army) Dwight D. Eisenhower arrived to take command of the European Theater of Operations, United States Army (ETOUSA).

Approval of the 1943 invasion—landings on a wide front between Boulogne and Le Havre, or Roundup, as it was called—did not solve the problem of what to do in 1942. That summer, President Roosevelt became increasingly convinced of the need for active operations in the European area before the end of the year. The commencement of a new German offensive in the USSR in June and British reverses in North Africa had their effects on his thinking. Fortunately, two decisive naval victories over the Japanese in May and June (Coral Sea and Midway) relieved the immediate threat to Australia and made it possible for the United States to divert greater resources to Europe. Despite the recommendations of General Marshall and Adm. (later Admiral of the Fleet) Ernest J. King, United States chief of naval operations (both of whom considered a North African venture a dispersal of strength), Roosevelt accepted a British proposal to invade North Africa that year (Operation Torch). The CCS appointed Eisenhower to assume immediate control of the planning. The decision to invade North Africa placed the Bolero-Roundup concept in jeopardy. Though planning for an eventual cross-Channel operation continued, Torch absorbed almost the entire effort and attention of the Allies in the European area. The invasion on Nov. 8, 1942, and the subsequent campaign through the winter and spring drained men, matériel, and supplies from the American buildup in the British Isles.

Meanwhile, the British had executed two daring raids against the German-held French coast. In March 1942, specially trained troops

called **Commandos** launched a hit-and-run foray against St.-Nazaire and destroyed submarine pens and other naval facilities. In August, a joint British and Canadian command, with 5,000 Canadians, 1,000 British, and 50 United States Rangers, raided Dieppe in a miniature invasion to test amphibious tactics and techniques. Involving the full use of combined arms and the mass landings of infantry and armor to seize a beachhead, the Dieppe operation was designed not to hold a beachhead but rather to test the ability of the newly developed LCT (landing craft, tank) to land tanks across beaches, to see whether it was possible to capture a port in a frontal assault, to scrutinize the organization of air forces for overhead cover and support, and to test the naval management of a considerable invasion fleet. Of the 6,100 troops embarked for Dieppe, about 2,500 returned, including about 1,000 who never landed. The others were killed or captured.

Plans Developed.—When the CCS met at Casablanca in January 1943, it was a time of optimism. The Germans had been decisively defeated in North Africa, though the campaign would continue until May. The Russians had taken the offensive after stopping the Germans at Stalingrad (now Volgograd), and Japanese expansion in the Pacific had definitely been checked. As a consequence, the greatest obstacle blocking offensive operations against the European continent that year was the relative paucity of Allied resources, particularly the shortage of shipping due to the effectiveness of German submarine warfare.

To make the Mediterranean safe for shipping, the Allies at Casablanca decided to invade Sicily after completing the conquest of the North African shore. By seizing Sicily, they hoped also to remove Italy from the war. To increase pressure on Germany, they agreed to initiate intensified air attacks from the United Kingdom, called the combined bomber offensive (Operation Pointblank). But for a major invasion across the Channel in 1943 the Allied leaders judged their resources insufficient. Though they set up a combined command and planning organization, it was designed to plan for small-scale raids and a return to the Continent in 1943 only if the Germans collapsed. A full-scale invasion was reserved for 1944.

Studying the Dieppe experience, the CCS planners concluded that the strength of the enemy defenses along the Channel coast required an immense concentration of power in the initial assault. Instead of dispersed landings, instead of many separate assaults by regimental and Commando units, it was better to make a single main landing. The beachhead initially secured should then be expanded and developed into a lodgment for the entire invasion force scheduled to follow. The area of initial assault and subsequent lodgment had various requirements. It had to be within range of fighter planes based in the United Kingdom; it had to provide airfields and sites suitable for constructing airfields soon after the invasion; it had to have at least one major port; and the landing beaches had to be sheltered from winds, suitable for prolonged maintenance operations, provided with adequate exits, and backed by good road nets. Furthermore, naval shelling, air bombardment, or airborne landings would have to be capable of reducing or crippling the beach defenses. The area most appropriate

for initial landings, the planners decided, was the Channel coast of France between Caen and Cherbourg.

When the CCS approved this analysis on March 1, 1943, they transmitted it as the basic paper for cross-Channel planning to Lt. Gen. (later Sir) Frederick E. Morgan, a British officer appointed that month as chief of staff to the supreme Allied commander (COSSAC). In a subsequent directive issued on April 23, the CCS instructed Morgan to set up an Allied headquarters for the supreme commander, who had yet to be named, and to plan to invade northwestern Europe as early as possible in 1944. Meanwhile, in February 1943, General Eisenhower, the supreme Allied commander in the Mediterranean, had relinquished command of ETOUSA, with its headquarters in England, to Lt. Gen. Frank M. Andrews. In May, when Andrews died in an air accident, Lt. Gen. (later Gen.) Jacob L. Devers took his place.

In May 1943, at the Trident Conference in Washington, the CCS enlarged the Allied bomber offensive from the United Kingdom, decided to exploit the projected Sicily operation to ensure the elimination of Italy from the war, and set a target date for a cross-Channel operation on May 1, 1944. In the future, men, matériel, and supplies were not to be diverted from the Bolero buildup for Mediterranean operations; on the contrary, 7 Allied divisions were to return from the Mediterranean area to the United Kingdom. The Allies visualized 29 divisions available for the invasion of France by the spring of 1944.

The reason for this optimistic estimate was the success of Allied warships and planes in destroying a growing number of German submarines during the spring of 1943. The decrease in shipping losses, combined with an increase in shipyard production and the freezing of resources in the Mediterranean, made possible a tremendous buildup of American forces in the United Kingdom. It was predicted that 1,300,000 United States troops (400,000 air force and 900,000 ground combat and service troops, including more than 18 combat divisions) would be in the United Kingdom by May 1944.

During the summer of 1943, COSSAC formulated three plans: Cockade, essentially a deception operation designed to pin German forces down in the west by encouraging their expectations of an Allied invasion that year; Rankin, a blueprint for occupying the Continent in case of a sudden German collapse; and Overlord, an invasion in the Caen-Cotentin area with an initial assault of from 3 to 5 divisions. In reality a concept to be used as the basis for later detailed planning, Overlord accepted the risk of prolonged beach maintenance by depending on the development of two prefabricated ports (code named Mulberries) to be towed across the Channel during the invasion. Under Overlord the initial mission of the invasion forces was to gain a lodgment area between the Seine and Loire rivers in France. As increasing numbers of combat units entered the lodgment area, ports, airfields, and supply installations would be developed and organized to support a subsequent drive toward Germany.

The planners assumed that it would take three months to secure lodgment. They then expected a pause for logistical reasons before an advance could be made beyond the Seine. Because they anticipated that the Germans would destroy the

facilities of Cherbourg and Brest, they thought of developing a major port of entry for United States forces on the south shore of Brittany at Quiberon Bay (Operation Chastity).

The Allied conquest of Sicily (July–August 1943), the fall of Benito Mussolini (July 25), negotiations for the surrender of Italy (eventually announced on September 8), and preparations for an Allied invasion of the Italian mainland (to be initiated on September 3), together with the Soviet seizure of initiative on the eastern front, provided a bright background for the CCS meeting at Quebec in August 1943. Though the CCS accepted COSSAC's Overlord concept, the debates between the Allies demonstrated divergent points of view. The British espoused a strategy essentially opportunistic, a view that reemphasized peripheral operations aimed at reducing German power by indirect attack (increased air and sea operations, plus intensified ground operations in the Mediterranean) in order to make the cross-Channel attack a success without question. They favored leaving the timing of Overlord somewhat indefinite. The Americans, wanting a power thrust to be made as quickly as possible, urged a definite commitment for Overlord, preferably May 1. The result was a compromise. Though May 1 remained the target date, it was not an altogether firm commitment. Yet the Allies agreed to give Overlord strict priority over operations in the Mediterranean. Accepting COSSAC's wish for a diversionary invasion of southern France, the CCS instructed General Eisenhower to draw plans for an operation to be executed from Mediterranean resources, timed to coincide with Overlord, and designed to gain lodgment in the Toulon-Marseille area, with a subsequent exploitation to the north and a juncture with the Overlord forces.

Selection of Commanders.—Selecting a supreme commander for the cross-Channel invasion was no easy matter. When an invasion in 1943 had seemed possible and the bulk of the resources would have been British, Churchill had informed General Brooke that he was to command the invasion forces. Later, when the preponderance of American resources dictated the choice of an American commander, Roosevelt and the British as well inclined toward General Marshall. But because Roosevelt wished Marshall to remain in control of the over-all American effort (Marshall was invaluable in balancing the sometimes conflicting demands of the Pacific and European theaters), the president, in December 1943, appointed General Eisenhower supreme commander of the Allied Expeditionary Force. Eisenhower's chief of staff, Lt. Gen. (later Gen.) Walter Bedell Smith, transformed the COSSAC staff into the Supreme Headquarters, Allied Expeditionary Force (SHAEF), with General Morgan remaining as deputy chief of staff. Eisenhower assumed his new position on Jan. 16, 1944, and General Devers was transferred to North Africa as commander of United States forces in the Mediterranean.

Gen. (later Field Marshal) Sir Bernard Law Montgomery (later 1st Viscount Montgomery of Alamein), who had led the Eighth Army in North Africa, Sicily, and Italy, was at the same time named to command the Twenty-first Army Group, the supreme British headquarters for the invasion. Eisenhower directed Montgomery to act as ground force commander during the initial phase of the invasion but reserved for himself the

eventual control of the Allied land forces. The major ground commanders were Lt. Gen. (later Gen.) Sir Miles C. Dempsey, who commanded the British Second Army; Lt. Gen. (later Gen.) Henry D. G. Crerar, in command of the Canadian First Army; and Lt. Gen. (later General of the Army) Omar N. Bradley, who took command of the United States First Army and of the United States First Army Group (later renamed the Twelfth Army Group). Lt. Gen. (later Gen.) George S. Patton, Jr., placed in command of the United States Third Army, was to head the immediate American follow-up force.

Eisenhower's deputy commander, Air Chief Marshal Sir Arthur W. Tedder (later 1st Baron Tedder), acted as coordinator of the air forces; the tactical air forces organized under Air Chief Marshal Sir Trafford L. Leigh-Mallory, who commanded the Allied Expeditionary Air Forces (AEAF); and the strategic air forces, composed of the RAF Bomber Command, under Air Chief Marshal Sir Arthur T. Harris, and the United States Strategic Air Forces under General Spaatz. Adm. Sir Bertram H. Ramsay took command of the naval forces for the invasion, with Rear Adm. (later Admiral of the Fleet) Sir Philip Vian commanding the Eastern Naval Task Force, scheduled to transport British troops, and Rear Adm. (later Adm.) Alan G. Kirk the Western Naval Task Force, which was to carry the American assault forces.

Final Plans.—After studying the Overlord concept, Generals Eisenhower and Montgomery concluded that the initial assault needed to be strengthened and yet made on a broadened front. This required additional landing craft, troops, and vehicles, and this in turn led to debate over whether the diversionary invasion on the Mediterranean coast of France, an operation code named *Anvil*, was really necessary. When the Anzio beachhead in Italy exerted its requirements for shipping, Eisenhower in March 1944 suggested canceling *Anvil* as an attack simultaneous with Overlord. In accepting the recommendation, the CCS assured SHAEF of the additional landing craft and other matériel needed for a stronger cross-Channel attack, but the complex requirements of assembling the means for the invasion of Europe had made it necessary to change the landing date from May to June. Meanwhile, on February 1, Montgomery, Ramsay, and Leigh-Mallory had drawn the initial joint plan (*Neptune*) for the invasion. A refinement of the Overlord concept, *Neptune* was at the same time a directive instructing the subordinate headquarters to plan the assault in greater detail.

As finally completed in the spring of 1944, the invasion plan called for assaults by the United States First and British Second armies. The First Army was to invade the Normandy shore in the Carentan-Isigny area with two corps. Northwest of Carentan the 82d and 101st Airborne divisions were to drop near Ste.-Mère-Eglise in order to assist the 4th Infantry Division of the 7th Corps to land on Utah Beach near Varreville. East of Isigny, in the 5th Corps zone, the 1st Infantry Division with part of the 29th Division was to land over Omaha Beach near Vierville-sur-Mer. Operating in the Bayeux-Caen area, the British were to send the 50th Division under the 30th Corps across Gold Beach near Arromanches-les-Bains, the Canadian 3d Division under the 1st Corps across Juno Beach near Courseulles, and the 3d Division, also under

the 1st Corps, across Sword Beach near Lion-sur-Mer. The 6th Airborne Division was to drop northeast of Caen near the mouth of the Orne River to protect the British flank.

The troops making the amphibious landings were to be carried by naval transports to positions 11 miles offshore in the American zone and 7 miles offshore in the British zone. The troops then were to board LCV's (landing craft, vehicle and personnel) and LCA's (landing craft, assault), each craft carrying about 30 men. The small craft were to go in abreast in waves and touch down at regular intervals along the length of the assault beaches. Following them were to be larger craft carrying heavy weapons, guns, tanks, and engineer equipment. Finally, LST's (landing ships, tank) were to nose onto the beaches and disgorge additional men, equipment, and supplies. Naval fire-support plans emphasized neutralizing enemy positions rather than destroying them. The air forces planned to maintain an umbrella of fighter planes to protect the ground and naval units from German air attacks and also to provide air bombardment to help the ground forces overcome obstacles impeding their progress ashore.

Long before the day of invasion, called D-day, the air forces had begun to play a significant preparatory role. Since 1942, British and American airmen had bombed military targets in German-occupied Europe, but no clear directive or over-all plan had existed before the combined bomber offensive directed by the CCS at Casablanca in January 1943. The targets of this offensive were the German industrial and economic systems and the morale of the German people. The Americans favored daylight precision bombing to destroy critical sectors of German industry. Believing daylight bombing too costly, the British favored night bombardment aimed at destroying entire industrial and military areas. Each operated according to its own doctrine, both concentrating on submarine construction yards, airplane factories, transportation systems, oil plants, and other war industries. In October 1943, attempts were first made to coordinate the bombings from North African and Italian bases with the combined bomber offensive from the United Kingdom.

In April 1944, Eisenhower took control of the strategic air forces and used them in support of Overlord. Though the over-all mission of destroying the German military and economic system remained, the particular mission was to deplete the German Air Force and destroy the facilities serving it, to destroy the German oil industry, and to disrupt rail communications, especially those that might serve the Germans in moving reinforcements to the Overlord lodgment area. Heavy air attacks in May 1944 shifted to bridges over the Seine, Oise, and Meuse rivers, and by June Allied air attacks had weakened the railroad transportation system in France to the point of collapse.

French Resistance.—Contributing toward the disruption of the railroads and highways in France were the efforts of the French resistance, a movement that had sprung up spontaneously after the surrender of France in 1940. As early as that year a headquarters established by Gen. Charles de Gaulle in London formed a special staff which was charged with organizing, directing, and supplying resistance units. For more than two years this agency worked to amalga-

Établissement Cinématographique des Armées

Top: A group of French civilian guerrilla fighters, taken prisoner by the Germans, is lined up to be shot. **Bottom:** In August 1944, as Paris is liberated, German troops surrender to a detachment of Free French forces.

mate the autonomous resistance groups. The culmination of its efforts was the formation of a National Resistance Council, which met for the first time in Paris on May 27, 1943, under the presidency of Jean Moulin. Representing not only the main resistance groups but also the principal political parties, the council recognized de Gaulle and his London headquarters as trustees of the French nation, responsible for founding eventually a French government based on democratic principles. De Gaulle's personal representative, Moulin, became the political leader of the resistance, and the National Resistance Council created an underground army organized on a regional basis. In the following month the Gestapo smashed the organization by making wholesale arrests. Moulin died under torture, and the leadership was decimated. The result was the decentralization of the resistance and its concentration on sabotage and paramilitary action.

Beginning in November 1940, the Special Operations Executive (SOE), a British organization, encouraged, directed, and supplied the French resistance. Operating under the minister of economic warfare, the SOE eventually had the aim of developing the resistance into a strategic weapon that could be directed by Allied headquarters against military objectives in accordance with a master plan. The SOE therefore set up and maintained communications between London

and resistance centers in France, parachuted agents into the country beginning in the spring of 1941, and dropped such supplies as explosives, small arms, flashlights, and radios. In 1942 the SOE parachuted 17 radio operators and 36 other agents into France.

At the beginning of 1943, when the Germans put into effect a forced labor draft in France, thousands of young Frenchmen, particularly in central and southern France, rebelled. To escape the draft, they formed *maquis* bands to conduct guerrilla warfare against the Germans and the collaborationist French Militia. The SOE assisted by increasing the amounts of supplies dropped into France. The American Office of Strategic Services (OSS) began to take part in the underground movement at this time by sending its own agents into France in cooperation with the SOE. The London headquarters of the OSS was fused with the British agency in January 1944, when American planes also began to fly supply missions to the resistance.

In the fall of 1943, COSSAC took responsibility for directing those aspects of the partisan and underground movements on the Continent insofar as they related to invasion plans. SOE and OSS operations came under the control of COSSAC and eventually under General Eisenhower's headquarters, SHAEF. Because it was hard to assess resistance strength, because German arrests could suddenly emasculate the movement, and because control of resistance activities was difficult and uncertain, the Allied planners decided to regard resistance help as a bonus rather than trying to use it to gain strategic objectives. Consequently, the underground army in France, numbering about 200,000 men, confined itself to gathering and transmitting intelligence information and performing sabotage in war industries, against railroads and canals, and against telephone and telegraph facilities. Accelerating its sabotage in 1944 against German troops and supply trains, the resistance cut tracks, destroyed bridges, and damaged locomotives in a campaign closely attuned to the Allied air offensive.

In late May and early June, in order to regularize the resistance activities, General de Gaulle, with the blessing of the Allied leaders, established a headquarters and staff in London for the French Forces of the Interior (FFI), with Gen. Joseph P. Koenig in command. The FFI then became a component of the Allied armies under Eisenhower, the supreme Allied commander. To link the resistance groups in France more closely to the Allied command, so-called Jedburgh teams (consisting of a French and an American or a British officer, plus a radio operator) were parachuted into France in uniform shortly before D-day. About 87 teams were operational in France at one time or another. Though it is difficult to evaluate the effectiveness of the resistance, there is no doubt that it was a moral as well as a material force that contributed to the eventual defeat of the Germans.

German Forces.—On the German side, Adolf Hitler exercised direct control over military operations. He was the supreme commander in chief of the armed forces (*Wehrmacht*). His staff was the High Command of the Armed Forces (*Oberkommando der Wehrmacht* or OKW), headed by Field Marshal Wilhelm Keitel. Under OKW, in theory, were the Air Force High Command (*Oberkommando der Luftwaffe* or OKL), headed

by Reich Marshal Hermann Goering (Göring), the Navy High Command (*Oberkommando der Kriegsmarine* or OKM), under Grand Admiral Karl Doenitz (Dönitz); and the Army High Command (*Oberkommando des Heeres* or OKH), headed by Hitler. In actuality, OKH directed the Russian campaign, while OKW was responsible for western Europe.

Navy Group West and the Third Air Fleet controlled naval and air forces in western Europe. The ground force field command was the *Oberbefehlshaber West* (OB West), which acted somewhat like a theater headquarters under Field Marshal Gerd von Rundstedt, the commander in chief in the west, who operated under Hitler's close supervision. The operations staff of OKW, the *Wehrmachtführungsstab* (WFSt), under Col. Gen. Alfred Jodl, was the direct agent between OB West and Hitler. Rundstedt controlled two army groups: Army Group G under Col. Gen. Johannes Blaskowitz, responsible for the Mediterranean (Nineteenth Army) and Atlantic (First Army) coasts of France; and Army Group B under Field Marshal Erwin Rommel, charged with defending the Channel coast with the Seventh and Fifteenth armies.

The chain of command that operated at the time of the invasion was Hitler, who made his wishes known through the WFSt of OKW (Jodl), to OB West (Rundstedt), to Army Group B (Rommel), and then to the Seventh Army, which was responsible for defending the lodgment area designated by the Overlord plan as the objective of the invasion force.

The steady drain of the eastern front left the Germans in France with two kinds of units, old divisions that had lost many good men and much equipment, and new divisions that were either of excellent combat value or were only partially equipped and trained. In June 1944, Rundstedt had 58 combat divisions, of which 33 were static or reserve divisions classified for limited defensive employment, 24 were well trained and equipped, and 1 was still being equipped. All the infantry divisions were committed on or directly behind the coast under one of the four armies or the armed forces commander in the Netherlands. The Seventh Army controlled Brittany and most of Normandy; the Fifteenth Army, the Pas-de-Calais.

The command in western Europe had its peculiarities. Rundstedt, for example, had no command over the Third Air Fleet, which was directly subordinate to OKL. The aircraft in France were too few in number for decisive effect; of the 400 fighter planes based in France, only half were operational because of shortages of spare parts, fuel, and trained pilots. Nor did Rundstedt control Navy Group West, under OKM, even though the destroyers, torpedo boats, and smaller naval vessels were based in ports within his jurisdiction. The air force had administrative control over parachute troops and antiaircraft artillery units; the navy controlled most of the coastal artillery. In addition, two military governors, one in France and the other in northern France and Belgium, were under OKH, though their security troops could be appropriated by Rundstedt to repel an invasion. Rommel, the Army Group B commander, was under Rundstedt, but Rommel's dominant personality and his prerogative of direct communication with Hitler, a prerogative enjoyed by all field marshals, gave him an influence greater

than that due his formal command authority.

Rundstedt favored maintaining a mobile reserve to be rushed to the invasion area when the main landings were recognized. Rommel, believing that Allied air superiority would prevent the movement of a mobile reserve to the landing beaches to repel the invaders, depended exclusively on fortifications near the water's edge. Thus Rommel directed much of his efforts to building coastal defenses. He favored a large number of simple, field-type defenses over a few complicated and massive fortifications. He emphasized the use of mines, underwater obstacles, stakes, Belgian gates, tetrahedra, and hedgehogs in the hope of entangling the Allied troops as they landed and making them vulnerable to those who waited at the shore to repel them. Rommel's construction and minelaying required considerable labor. Because Organization Todt, the construction agency of the German Army, was employed chiefly in major port fortress areas and on railroad maintenance, the troops themselves worked on the Atlantic Wall in 1944, in many cases to the detriment of their training programs.

By the time of the invasion a new weapon was ready to be put into operation. This was the air missile called the V-1, for *Vergeltungswaffe* (vengeance weapon). From the Pas-de-Calais area the Germans would begin on June 13 to launch these flying bombs against England and its civilian population as a reprisal for Allied air attacks on German cities. In September, the V-2, a deadlier supersonic rocket, would be introduced.

Deception Plan.—One of the vital elements of the invasion was the erroneous German expectation of landings in the Pas-de-Calais. Believing that a number of Allied divisions in the United Kingdom belonged to "Army Group Patton," the Germans concentrated a strong Fifteenth Army in the Pas-de-Calais, the coastline nearest to England and the area in western Europe

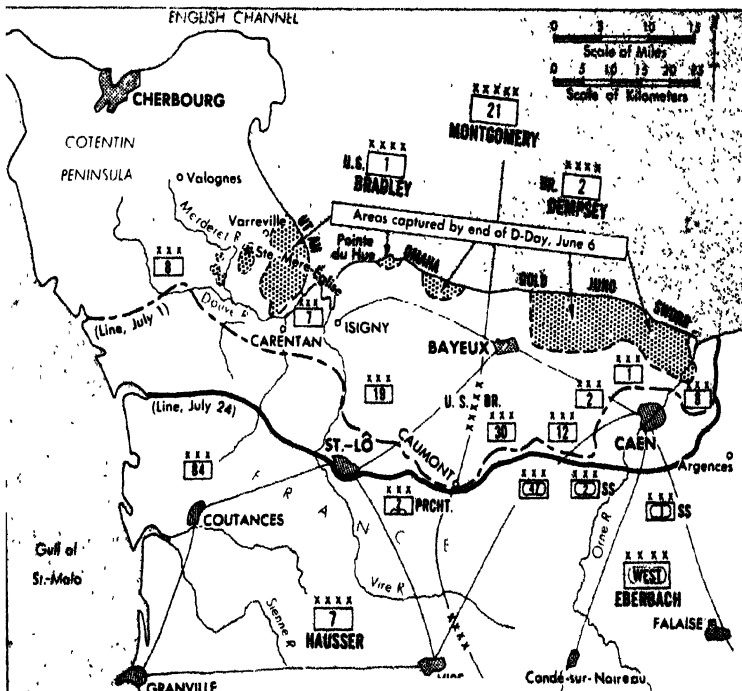

closest to the classic invasion routes into Germany. The Allies nourished this belief by a gigantic deception plan designed to convince the Germans that Overlord was only part of a larger invasion effort. Naval demonstrations off the Channel coast, false messages, dummy installations, and other signs of impending coastal assault kept the Germans in a continual state of alert and alarm and immobilized the considerable force of the Fifteenth Army.

The Allied hoax continued well beyond the Overlord invasion. Early in July, the designation of the United States First Army Group was changed to the Twelfth in order to retain in England a fictitious headquarters that the Germans might think capable of launching another invasion. Lt. Gen. Lesley J. McNair, commander of the Army Ground Forces, who was visiting the European theater, was placed in command of the fictitious army group. Later, when McNair was killed while observing the battle in Normandy, Lt. Gen. John L. De Witt was rushed to England in order to give continuing verisimilitude to the Allied deception measures. When the Third Army was committed on the Continent, Patton's name was at first kept secret for the same reason. Eminently successful, the deception maneuvers fooled the Germans for nearly five months. During the invasion and the subsequent battle for Normandy, when the Germans could well have used reinforcements from the Pas-de-Calais area, the Fifteenth Army remained untouched and immobile, awaiting an invasion that never came.

INVASION AND CAMPAIGN FOR NORMANDY

Invasion.—On May 8, General Eisenhower designated D-day as June 5, but because of bad weather he decided on June 4 to postpone the invasion to June 6. Though the weather remained poor, further delay would have necessitated waiting until June 19, when tidal conditions and

Map 9. ESTABLISHMENT OF THE NORMANDY BEACH-HEAD (June 6–July 24, 1944). German opposition to the landings was strong at all beaches except Utah Beach, and it was particularly fierce at Omaha. Nevertheless, by nightfall of the first day the Allies held footholds on the shore as shown. During the succeeding days no serious counterattacks developed, for the Germans had been deceived into believing that the main landings were still to come farther north, in the Pas-de-Calais area, and were husbanding their forces to counter them. By July 1, the Allies had landed almost 1,000,000 men and had cleared most of the Cotentin Peninsula. By July 24, the line had been advanced as shown, and the American forces stood poised to strike southward at St.-Lô.

Early in the morning of D-day, June 6, 1944, men of the United States 1st Division, pinned down by German fire off Omaha Beach in Normandy, take shelter behind underwater obstacles of the coast defenses.

Robert Capa-Magnum

the light of the moon would again have been propitious. In one of the most momentous decisions of the war he decided to proceed despite the unfavorable weather conditions. Meanwhile, the invasion troops had moved to concentration areas in the United Kingdom. There they received special equipment and waterproofed their vehicles. Then they marched to marshaling areas close to the embarkation points, where the troops received additional supplies, maps, and final briefings. About 60,000 men and 6,800 vehicles were scheduled to go ashore on D-day at Omaha Beach and equal numbers at Utah. On D plus 1 and 2, an additional total of 43,500 troops and 6,000 vehicles were scheduled to go ashore at both beaches. Roughly equal numbers were to land on the British beaches. Altogether in the United Kingdom, General Eisenhower had a force of 2,876,000 men, including 45 divisions.

Some 5,000 ships and craft made up the invasion fleet. During the night of June 5, despite a gusty wind blowing at a rate of 15 to 20 knots and churning up waves in mid-Channel as high as five and six feet, the invasion fleet took assigned places in the transport areas off the coast of France in the Seine Estuary. Minesweepers cleared and marked 10 lanes through minefields in the Channel. In the early minutes of June 6, RAF bombers ranged the entire invasion coast, striking at coastal batteries and other targets. In the second hour, paratroopers of the 82d and 101st Airborne divisions landed in the eastern part of the Cotentin Peninsula astride the Merderet River to facilitate the seaborne landings of the 7th Corps. The 101st Division secured its objectives with surprisingly light losses, but the 82d had to fight severely, taking heavy casualties, to secure Ste.-Mère-Eglise. At the same time the British 6th Airborne Division was securing the other Allied flank between the Orne and Dives rivers. As dawn approached, while fighter squadrons flying at from 3,000 to 5,000 feet maintained an aerial umbrella, the landing craft came toward shore through a heavy sea.

Because lack of planes in France denied adequate aerial reconnaissance, the Germans had no advance knowledge of the invasion. They also relied on the bad weather, considering it too inclement for the Allies to try an invasion at that time. Their first reaction occurred early in the morning of June 6, when several German torpedo boats left Le Havre to engage the invasion fleet. They were driven off by Allied naval fire and air attack. The German coastal batteries began to fire sporadically at the invasion fleet at 5:35 A.M. At 5:50 A.M., the Allied naval bombardment began. This fire not only detonated large mine fields, on which the Germans had counted heavily to block the invaders, but also knocked out many defensive installations.

At 6:30 A.M., H-hour for the United States beaches, American troops touched down on Omaha and Utah beaches. At Utah the 4th Division and the 7th Corps had little difficulty getting ashore against intermittent artillery shelling. The beach area was cleared in three hours, and the

follow-up troops and supplies began to come ashore with little trouble. About 23,000 men landed that day. At Omaha, where the 1st Division of the 5th Corps assaulted with two regiments abreast, high seas, early morning mist, smoke, dust, and a lateral current scattered men and units badly. German fire was exceptionally strong, and many wounded Americans were drowned in the rising tide. In a daring operation two Ranger battalions took out large coastal guns at Pointe du Hoc after scaling cliffs with rope ladders, but after the first three hours of the invasion it appeared for a while that the Omaha invaders had been stopped on the beach. The presence of an elite German infantry division that for three months had escaped Allied intelligence accounted in large measure for the difficulties of the 5th Corps. Only through improvisation and courageous personal leadership were the troops at last able to get off the beach and onto the cliffs beyond. Even then the infantry had very few heavy weapons and no supporting artillery. The beach was congested with disabled and burning vehicles, and the beachhead was a strip of land less than 2 miles deep. Nevertheless, as night fell, 34,000 men were ashore.

Troops of the British Second Army meanwhile began to land at 7:20 A.M. On Gold Beach the advance elements of the 50th Division were pinned down at first by German fire, but gradually they worked their way around the resistance and pushed rapidly inland. By the end of the day they had advanced about 5 miles. The Canadian 3d Division on Juno Beach met even stiffer resistance, but once clear of the beaches the Canadians moved rapidly and by the end of the day had reached the Caen-Bayeux highway. The British 3d Division on the left also met intense opposition on Sword Beach, but by the end of the day linked up with the 6th Airborne Division.

Despite the immense problems at Omaha Beach, the Allies by the end of D-day had established apparently solid footholds on the Continent. Casualties everywhere, including bloody Omaha, were lighter than expected. They were lightest of all at Utah Beach (less than 200), though the airborne divisions behind the beach lost 2,499 men, including 338 known dead and 1,257 missing. At Omaha the Americans lost approximately 2,000 men. British and Canadian casualties were about 4,000.

Though German opposition had been firm on all beaches except Utah and particularly disturbing at Omaha, D-day passed with a surprising lack of counterattacks. Only near Caen, where a panzer division in late afternoon struck the British 3d Division, was there more than passive resistance, and the 3d Division stopped this thrust with little loss of ground. The most significant German development was the ordering of a panzer corps to the Caen area, a harbinger of the fact that the Germans saw the British landings and their threat to open ground leading toward Paris as the Allied main effort.

By the end of D-day, the Americans had landed the equivalent of 8 regiments amphibiously. By the end of the following day, 5 divisions (including the 2 airborne divisions) were ashore and operational, though all were deficient in transportation facilities, tank support, artillery, and supplies. An ammunition shortage was serious, particularly on Omaha. The Americans had planned to have about 107,000 troops ashore by the end of the second day, but the total was approximately 20,000 short. Only about half the planned 14,000 vehicles had been disembarked, and only a fourth of the anticipated 14,500 tons of supplies were on the beaches.

Meanwhile, Eisenhower ordered Bradley's First Army to give priority to the task of linking the two American beachheads and of making contact with the British. In compliance with this order the 1st Division pushed eastward to gain contact with the British on June 8, the 29th Division took Isigny on June 9, and the 101st Airborne Division captured Carentan on June 12. With Carentan in hand and the beachheads joined, the 7th Corps turned its attention to Cherbourg. Halting further expansion inland of Maj. Gen. (later Gen.) Leonard T. Gerow's 5th Corps, which had taken Caumont and was near the road center and departmental capital of St.-Lô, Bradley on June 13 placed the bulk of the incoming resources at the disposal of Maj. Gen. (later Gen.) J. Lawton Collins' 7th Corps. During the night of June 17, the 7th Corps cut the Cotentin Peninsula and sealed off Cherbourg from German reinforcement. Two days later, Collins began to push northward toward the port city with 3 divisions. Organized resistance in Cherbourg ceased on June 27. Meanwhile, headquarters of the 19th Corps, commanded by Maj. Gen. Charles H. Corlett, had entered the line near St.-Lô on June 14. Maj. Gen. (later Lt.

Gen.) Troy H. Middleton's 8th Corps also arrived and took control of the forces at the base of the Cotentin Peninsula on June 15. The British had meanwhile captured Bayeux and expanded and enlarged their beachhead, but Caen, a D-day objective, remained out of reach.

In these early days the Allies used two methods to get supplies ashore: direct discharge onto the beach from landing craft and unloading the cargo carried by larger vessels moored offshore into ferry craft and DUKW's (amphibious trucks) for transport either to the beach or to the artificial ports (Mulberries). Not until the destroyed facilities at Cherbourg were repaired in mid-July was this port to begin to take some of the logistical strain from the beaches. A great storm that raged between June 19 and June 22 wrecked scores of craft and smashed the artificial harbors. High winds demolished the American Mulberry beyond repair, but the British artificial quay was later restored to full use. Nearly 100 LCVP's and LCM's, plus many LCT's and larger craft, were lost and 19 of 20 rhino ferries were destroyed. Despite this calamity, which stopped unloading operations for several days, the Allies developed an ability to bring ashore over the open beaches surprisingly large amounts of tonnage.

By July 1, three weeks after the initial landings, the first phase of the invasion came to an end. Almost 1,000,000 men, more than 500,000 tons of supplies, and 177,000 vehicles had been landed in the American and British zones. A total of 27 Allied divisions had arrived on the Continent, and more were about to come. The German's golden opportunity to smash the invasion by decisive counterattack before the Allies were firmly established had passed. German failure to react in strength was attributable to the condition of the French railroads and to unrelenting air attacks that enabled German divisions to reach the battle zone only with utmost difficulty and after serious delays. Units arrived piecemeal, often lacking essential weapons and short of fuel and ammunition. Continuing pressure of Allied attacks then forced German commanders to commit the new divisions as they arrived so that a major counterattacking force could never be assembled. The two leading German commanders on the scene, Rundstedt and Rommel, both were convinced that they now had no chance to drive the Allies into the sea. Persuaded that Germany had lost the war,

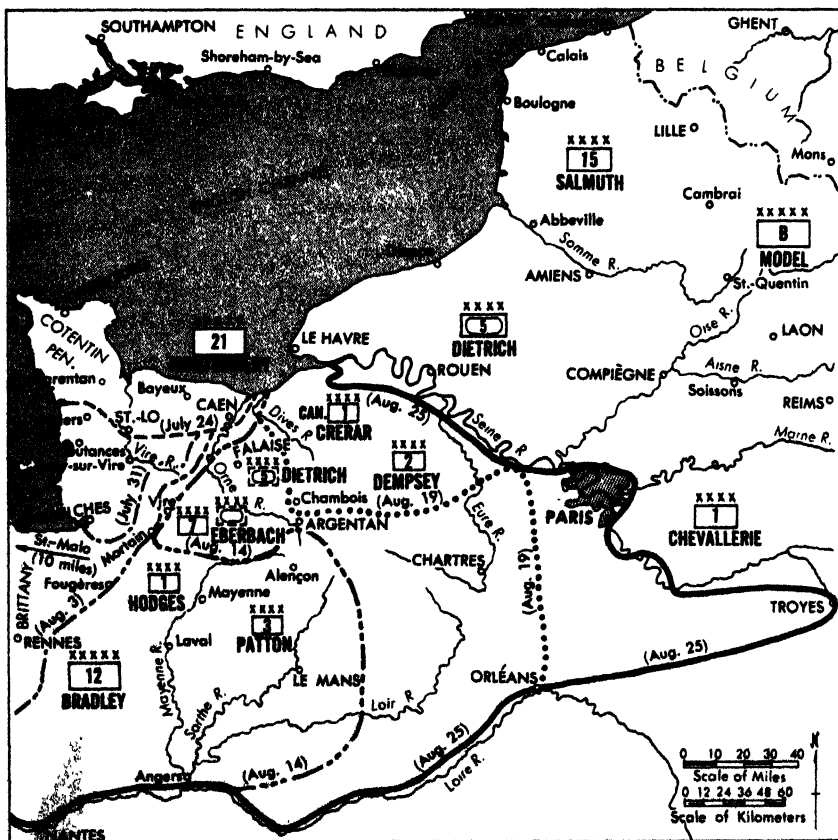

Rundstedt asked to be relieved from command. Granting the request, Hitler replaced him as commander in chief in the west with Field Marshal Hans Günther von Kluge. Rommel, though discouraged, remained. The strategy enunciated by Hitler for the western front was essentially negative: hold fast until miracle weapons might turn the course of the war.

Battle of the Hedgerows.—Despite Allied success in getting ashore in Normandy, the lodgment secured by the beginning of July was much smaller than had been anticipated. Because the British seemed stalled before Caen, Bradley's First Army initiated on July 3 the offensive that became known as the battle of the hedgerows. The hedgerows are walls, half earth and half hedge, that enclose the tiny fields in the Cotentin, the region south of Cherbourg. As each of four American corps launched an attack in turn, the Americans struck across a waterlogged and hedgerow-laced area that was perfectly suited to defense. Confined in a relatively small sector and confronted with difficult terrain and inadequate roads, the Americans fought an enemy favored by endless lines of natural fortifications (the hedgerows) and aided by daily rains which negated Allied tactical air support and reduced observation. Though inferior in numbers and deficient in supplies and equipment, the Germans inflicted 40,000 casualties on the First Army, which gained only a few miles of ground. The climax of the battle occurred on July 18, when the 19th Corps at last captured St.-Lô.

The British meanwhile had thwarted dangerous armored counterattacks at the end of June, and then secured half of Caen by launching a

massive attack on July 8 supported by heavy bombers. This was an unusual use of aircraft normally employed against strategic targets far in the enemy rear. In this attack, 460 planes dropped 2,300 tons of high-explosive bombs in 40 minutes. Following the aerial attack, British and Canadian ground troops, though hampered by bomb craters and debris-clogged roads, reached the Orne River, which flows through Caen. Ten days later, on July 18, General Montgomery launched a similar attack, code named Goodwood. After 2,100 planes dropped more than 8,000 tons of high explosive, British and Canadian ground troops advanced from Caen toward Falaise. Despite high optimism for a decisive penetration of the enemy defense line, the attack carried for only 6 miles before bogging down.

Rommel had on July 17 been eliminated from the battle when an Allied plane strafed his staff car and forced it into a ditch. Suffering a brain concussion, he was taken to a hospital. Kluge assumed his place, commanding both the theater headquarters and Army Group B. Three days later, on July 20, a conspiracy among German officers almost succeeded in assassinating the führer and gaining control of the government with the aim of ending the war. From this point on, Hitler became ever more suspicious of his subordinates. He eventually forced Rommel, who was implicated in the plot, to commit suicide. He took stronger control of battlefield operations. Though the plot had no visible effect on the campaign, the miracle of Hitler's survival impressed the German people and gave Hitler's unilateral direction of the war even greater strength.

Map 10. BREAKOUT FROM THE BEACHHEAD AND LIBERATION OF PARIS (July 25-Aug. 25, 1944)
 Preceded by an intensive bombardment, Lt. Gen Omar N. Bradley's attack south from St.-Lô on July 25 was highly successful and broke through the German lines. During the next week the American advance extended into Brittany and began to swing eastward to envelop the German flank. On August 7, the Germans counterattacked strongly at Mortain, but without success. Instead, their Seventh and Fifth Armored armies were almost encircled in the Falaise area by converging British and American advances. The Allied drive to the east against crumbling resistance made rapid progress. By August 25, it had reached the Seine River at several points; and on that day, Paris was liberated.

Breakthrough.—To penetrate the German defenses and make a limited exploitation to the town of Coutances, General Bradley on July 13 drew an outline plan called Cobra. This plan projected a heavy attack on a narrow front just west of St.-Lô, the ground effort to be propelled forward by a mighty air attack. Bradley concentrated 6 divisions under Collins' 7th Corps and called for support by heavy bombers. Some planes in Operation Cobra were already under way when overcast skies forced a day's postponement. Failing to receive word of the delay, approximately 350 bombers already over the target dropped around 700 tons of bombs, some of which struck American troops. On July 25, the operation officially got under way as 2,500 planes dropped approximately 4,000 tons of bombs on a rectangular "carpet" 7 miles long and 2 miles wide along the Périers-St.-Lô highway. Though some bombs again fell short and caused casualties among the American ground troops, 3 infantry divisions followed the bombardment closely and attempted to open a hole for exploiting forces. The Germans, though badly hurt, appeared to be holding, but commitment of 2 additional American divisions on the second day and a third on the next opened a tremendous breach. General Bradley had achieved his breakthrough. Modifying his plans, he broadened the scope of the operation, and all four corps of his First Army drove ahead. By the end of the month the 7th and 8th Corps in less than a week had advanced about 30 miles. Far beyond Coutances, Americans took Avranches and gained the base of the Cotentin. This made possible not only a swing to the west into Brittany but a swing to the east, around the German left flank, toward the Seine River and Paris.

The outstanding achievement of the last week in July was the result of many factors. The Americans had outmaneuvered the Germans. Hard fighting by the 19th Corps at Tessy-sur-Vire had blocked Kluge from sending two panzer divisions into the Cobra area to disrupt the breakthrough operation. Aggressive armored action, supported by tactical aircraft giving excellent close support, trapped considerable German forces near Coutances. Bradley's forces had, in effect, crushed the German left flank and thereby invalidated Hitler's tactic of standing fast until new developments in weapons might alter the situation. On August 1, Bradley turned over the command of the First Army to Lt. Gen. (later Gen.) Courtney H. Hodges. On the same day, General Patton's Third Army became operational. Both armies went under the command of Bradley, who became the commander of the Twelfth Army Group.

Breakout into Brittany.—Middleton's 8th Corps, now under the Third Army, turned west from Avranches and entered Brittany. One armored division drove to Rennes and then to Lorient, another armored division drove to Brest, and an infantry division moved to St.-Malo. The entrance of American troops into Brittany chased the Germans into these port cities, as well as St.-Nazaire and Nantes, which Hitler had designated as fortresses to be held to the last man. While small American forces contained the Germans in the port cities, siege operations got under way at St.-Malo, which was finally captured on August 17. The 8th Corps then moved to Brest and initiated siege operations on August 25. A fierce battle at that city finally ended on Sep-

tember 18. Meanwhile, headquarters of the United States Ninth Army, under Lt. Gen. William H. Simpson, had been committed in Brittany in order to provide control over operations that were increasingly farther behind the main front.

Though operations in Brittany had been undertaken with the object of gaining the port cities as points of entry for additional troops and supplies coming directly from the United States, the strong German defenses at St.-Malo and Brest

Troops of the United States 8th Corps enter La Haye-du-Puits in western Normandy. The town, first entered on July 5, was finally secured two days later.

Etablissement Cinématographique des Armées

and the accompanying destruction of the port facilities prompted a change in Allied plans. Not only did the Allies decide not to rehabilitate the destroyed port cities; they also decided not to commence constructing the port complex at Quiberon Bay, the project code named Chastity, for by this time Brittany was far removed from the main stage of operations. Early in August, the main Allied armies had swept eastward from Avranches.

Breakout to the East.—When the Third Army became operational on August 1, General Patton took control not only of the 8th Corps operations in Brittany but also of Maj. Gen. (later Gen.) Wade H. Haislip's 15th Corps, which turned southeastward toward Mayenne. Taking Mayenne on August 4, capturing Laval on August 5, and seizing Le Mans on August 8, the 15th Corps formed an enveloping pincer that extended more than 75 miles around the German left flank. Meanwhile, the First Army also swung southeastward toward the road centers of Vire and Mortain, thereby starting a swinging movement designed to carry the Allies to the Seine River and the periphery of the lodgment area envisioned by the Overlord planners. But the Germans turned and sprang. Hoping to regain Avranches and thereby to close the hole that Bradley had punched in their defenses, the Germans launched a counterattack at Mortain on August 7. They were motivated by the desire to reestablish the conditions of static warfare that had served them well during June and most of July. They struck the 30th Infantry Division of Collins' 7th Corps with full force. Quickly reinforced by Bradley, the 7th Corps fought a magnificent defensive battle to halt the German threat.

By attacking westward through Mortain toward Avranches, the Germans had placed their heads into a potential noose. Bradley saw the possibility of encircling the Germans and proposed this maneuver to Montgomery, who agreed. Bradley therefore directed Patton to turn the 15th Corps northward from Le Mans toward the successive objectives of Alençon and Argentan with the purpose of cutting behind the Germans at Mortain. If Montgomery's forces drove southward from the Caen area and reached Falaise, the Allies would form a pocket and threaten the enemy's Fifth Panzer and Seventh armies with encirclement and annihilation. General Crerar's Canadian First Army, which had become operational on the Continent on July 23, attacked southward toward Falaise on August 8, but gained little ground. In contrast, Haislip's 15th Corps took Alençon and was within sight of Argentan by August 13. Because the American troops had reached the boundary line separating American and British zones of operations, Bradley ordered Patton to halt further advance by Haislip's corps. This decision was dictated in part by the fact that Crerar was about to launch a heavy attack on the following day. On August 14, after 800 planes had dropped 3,700 tons of bombs to clear a path for the ground troops, the Canadians launched their attack. Two days later they reached Falaise. Allied forces were then only 15 miles apart, but the Germans were escaping eastward out of the pocket through this 15-mile sector, called the Argentan-Falaise gap.

Bradley had meanwhile approved Patton's plan to send part of the 15th Corps to the Seine.

This movement got under way on August 14. Five days later the 79th Division was crossing the Seine River and establishing a bridgehead on the east bank. Other troops of the 15th Corps, soon joined by the First Army's 19th Corps under Corlett, were driving down the west bank of the Seine and pushing the Germans toward the mouth of the river, where escape crossings were harder to find. While this second encirclement at the Seine was in progress, the Allied troops holding the shoulders of the first encirclement at Argentan and Falaise were at last making contact at Chambois and Trun. They thus closed the pocket on August 20, trapping more than 50,000 German troops, destroying an additional 10,000, and sending the Fifth Panzer and Seventh armies reeling eastward across the Seine in defeat. Field Marshal Walter Model meanwhile had become commander in chief in the west, replacing Kluge, who committed suicide.

By this time two more American corps had come on the scene. Maj. Gen. (later Gen.) Walton H. Walker's 20th Corps, after taking Angers, turned to take Chartres. Maj. Gen. Gilbert R. Cook's 12th Corps drove toward Orléans. By August 20, when the First and Third armies pulled up to the Seine, Eisenhower had already decided to ignore the original limits of the lodgment area and cross the river in strength in pursuit of the disorganized enemy force. Meanwhile, as British and Canadian armies moved to the Seine, American and French troops liberated Paris.

Liberation of Paris.—The climactic incident in the Normandy campaign was the liberation of Paris, which occurred almost by accident. In order to avoid a battle that would damage the French capital and inflict casualties on its inhabitants, General Eisenhower intended originally to bypass Paris. Hitler for his part wished to retain the city for the prestige involved, and he designated it a "fortress" to be fought over until it was, as he put it, "a field of ruins." The French wanted Paris liberated not only because its capture would signify a crowning achievement for the resistance, but also because it would establish General de Gaulle in the seat of government. Thus a three-cornered struggle developed, with the Germans preparing to fight on the western outskirts and, if necessary, inside the city, with the French putting pressure on Eisenhower to send troops to liberate the capital, and with the Allies preparing to go around the city in the more important pursuit to the German border and in the hope that the capital would fall into Allied hands once it was isolated. A spontaneous uprising within the city on August 19 changed all plans.

Lacking the means to put down the uprising in the face of Allied advances near the city and unwilling to destroy the capital, the German commander concluded a truce with the resistance leaders. Erroneous reports that the Germans were about to destroy the city before withdrawing, as well as news of grave food shortages in Paris, prompted Eisenhower to change his mind. When he directed Bradley to take the city, Bradley sent a Franco-American force under Gerow's 5th Corps to perform the act. Gen. Jacques Philippe Leclerc's 2d Armored Division was given the honor of the first entry into the city. But the German defenses on the outskirts of Paris proved stronger than had been anticipated. Though a small French unit penetrated into the

enter of the city around midnight of August 24, the actual liberation had to await the next day, when both French and American troops entered Paris. The German defense quickly collapsed, and the German commander surrendered.

INVASION IN THE SOUTH AND DRIVE TO THE EAST

Invasion of Southern France.—Even as Allied troops swept victoriously across Normandy, another Allied force staged a second amphibious invasion on August 15, this time on the south coast of France between Cannes and Toulon. This was the long-postponed Operation Anvil (also known as Operation Dragon). Though Eisenhower in the spring of 1944 had recommended that this invasion not be launched at the same time as the landings in Normandy, he wished only to gain additional landing craft for the major invasion, and neither the Allied commander nor other American officials endorsed abandoning the operation altogether. Against British resistance, notably from Churchill, who continued to favor expanded operations in other parts of the Mediterranean, Eisenhower had continued to believe an invasion of southern France essential to the success of Overlord.

Allied entry into Rome two days before the Normandy invasion at last made it clear beyond doubt that some resources could be spared from the Mediterranean to assist Overlord. After considering various operations, including an invasion of the southwest coast of France, Allied planners finally decided to strike the south coast on August 15, though all British objections did not end until shortly before the target date. The invasion was designed to prevent German forces in the south from moving against Overlord and to provide the Allies with a supplementary line of supply through the Mediterranean ports, particularly Marseille.

Behind a heavy air and naval bombardment three United States divisions (the 3d, 36th, and 45th) under the 6th Corps, commanded by Maj. Gen. (later Lt. Gen.) Lucian K. Truscott, and an attached French armored force began landing early on the morning of August 15 on either side of St.-Tropez. Meanwhile, a task force composed of American and British paratroopers landed behind the invasion beaches to cut roads and isolate the German defenders. The over-all commander was Maj. Gen. (later Lt. Gen.) Alexander M. Patch, commander of the United States Seventh Army. The German force responsible for defending southern France, Army Group G under General Blaskowitz, had only 11 divisions for the task. Though the German High Command had been considering the withdrawal of Army Group G to the north, no action had been taken when the invasion came. Their forces spread thin, the Germans could muster only spotty resistance on the beaches. Two days later, OKW ordered Blaskowitz to leave forces to hold the major ports and pull back toward the Vosges Mountains in northeastern France.

The success of the Allied invasion was spectacular. On the first day alone, 86,000 men, 12,000 vehicles, and 46,000 tons of supplies were put ashore. In only a few days the United States divisions were fanning out from the beaches and heading north up the Route Napoléon toward Grenoble. Under Gen. Jean de Lattre de Tassigny, a follow-up French force (later designated the French First Army) swung westward against Toulon and Marseille, where stubborn resistance

ended on August 28. On the same day troops of the 6th Corps seized Montélimar, 75 miles up the valley of the Rhone River, but were too late to trap German columns withdrawing from southwestern France. In two weeks the Allies nevertheless had opened two major ports and had taken 57,000 prisoners at a cost of only 4,000 French and 2,700 American casualties. American and French columns soon were matching the sweeping advances in northern France. French resistance forces swarming from the mountains aided the drive materially. As Lyon fell on September 3, the Allied forces turned northeastward toward the Belfort gap. On September 11, patrols from the southern force met patrols of Eisenhower's northern force near Dijon. Four days later, the troops in the south, organized now as the Sixth Army Group under the command of General Devers and composed of the United States Seventh and French First armies, came under General Eisenhower's command.

The invasion of southern France and the subsequent drive north succeeded beyond all expectations. The Germans lost 80,000 men in prisoners alone, while Allied casualties totaled 7,200, about equally divided between Americans and French. On the other hand, the Germans by their timely withdrawal managed to extricate more than half of Army Group G from entrapment. Having reached the foothills of the Vosges, the Germans turned to fight back. Though the Allies continued their attacks, a shortened German defensive line and overstrained Allied supply resources brought the sweeping gains to an end.

Pursuit Toward the German Frontier.—In the meantime, the main Allied armies in the north, having captured Paris and jumped the Seine on August 25, continued to pursue the Germans across northern France and Belgium toward the German border. In preinvasion planning, General Eisenhower had decided to advance against Germany on a broad front. He planned to make his main effort in the north through Belgium, passing Montgomery's Twenty-first Army Group to the north of the barrier of the forested Ardennes region of Belgium and Luxembourg along the most direct route to the Ruhr industrial area, the vast collection of coal mines and factories which was the main source of German industrial strength. Bradley's Twelfth Army Group was to advance south of the Ardennes through a lesser industrial area, the Saar. Yet as the extent of the German defeat became apparent, Eisenhower yielded to persistent demands from Montgomery to strengthen the forces in the north. Leaving Patton's Third Army to advance alone south of the Ardennes, he ordered Bradley to send Hodges' First Army north of the barrier alongside the British flank. This, Eisenhower reasoned, would speed Montgomery's capture of ports along the Channel, including the great port of Antwerp (Antwerpen). Another big port was essential to continued advance into Germany, for Brest, Cherbourg, and even Le Havre soon would be far behind the front. As General Crerar's Canadian First Army invested the minor Channel ports, Montgomery's troops dashed into Brussels (Bruxelles) on September 3 and the next day seized Antwerp. In the process, British and Canadians overran the V-1 launching sites which had been bombarding Britain since June. Though Antwerp fell with wharves and docks intact, the big port could not be used until the Germans were cleared from the banks of the Scheldt (Escaut, Schelde) Estuary, leading

60 miles to the sea. The British failed to turn a force immediately to this task.

The United States First Army meanwhile took Mons, Belgium, on September 3, trapping there 25,000 Germans who were trying to flee from the Channel coast, and then turned eastward toward Germany. Two days later, one corps was across the Meuse River. Liège fell on September 7, and the capital city of Luxembourg on September 10. As in France, resistance fighters materialized at many points, here preventing the retreating Germans from blowing a bridge, there dismantling a roadblock before the tank-led American columns arrived. On September 11, patrols of Gerow's 5th Corps crossed onto German soil. Patton's Third Army meanwhile captured Reims and Châlons on August 29, took Verdun, St.-Mihiel, and Commercy on August 31, and on September 7 established a bridgehead over the Moselle (Mosel) River south of Metz.

German Reorganization and Allied Supply Problems.—As patrols of the First Army crossed the German frontier and the troops from the invasion of southern France linked with those of Overlord, an early end to the war appeared not only possible but probable. The ragged columns falling back to the German border seemed thoroughly beaten, and on the eastern front Soviet armies, having driven the Germans from Russian soil, had begun to press into Poland. In the three months since the Allies had landed in Normandy, the Germans on all fronts had incurred more than 1,210,000 casualties. Day and night, British and American heavy bombers hammered German cities, factories, and rail lines. To many it seemed incredible that the divisions in the west, reduced to no more than half the strength of the 49 divisions which General Eisenhower had arrayed against them, could be rebuilt fast enough to forestall total defeat. Even most German commanders saw the only hope to be quick withdrawal behind the historic moat of the Rhine River.

On the other hand, Hitler from his position as over-all commander recognized that his Third Reich still possessed considerable power. He still had, for example, more than 10 million men in uniform. Despite Allied bombings, German factories still had been able to maintain a high rate of production and had yet to reach their wartime peak. Recognizing early in the summer that Germany could not hope to match the numbers of Allied tanks, Hitler had concentrated instead on producing heavier tanks that he considered tactically superior. These he ordered to be used to equip panzer brigades that might halt or delay the Allied armies until the shattered panzer divisions could be refitted and reorganized. By reducing the numbers of service troops, by converting sailors and airmen into infantrymen, and by at once lowering and extending the ages for induction into the armed forces, he ordered the early formation of 25 new divisions, all to support the western front. He also ordered into the line along the frontier 100 so-called fortress infantry battalions, heretofore used only in rear areas. Though Hitler could not hope to produce enough new airplanes to redress the tremendous imbalance in the air, he continued to put his faith in the early appearance of new jet-propelled planes. He also put considerable faith in a series of fortifications along the western border known as the West Wall. Called by the Allies the Siegfried Line, the fortifications had been constructed before the war from Switzerland to the point

where the Rhine enters the Netherlands. As much as 3 miles deep, the line consisted of hundreds of concrete pillboxes, observation posts, command posts, and troop shelters. Either such natural antitank obstacles as streams or concrete projections called dragon's teeth fronted the entire length.

Looking for a new commander who might rebuild the morale of the German soldier in the west, Hitler on September 5 recalled Field Marshal von Rundstedt as commander in chief. While Field Marshal Model remained as commander of Army Group B, Hitler charged Rundstedt with holding firm along the Dutch-Belgian border, in the West Wall, and along the Moselle River. As many as possible of the panzer divisions were to be regrouped quickly to counterattack into the south flank of the United States Third Army to cut off Patton's armored columns. The strength of the West Wall, when supplemented by the counterattack and the other emergency steps, would be sufficient, Hitler believed, to hold the Allies along the border until he could form a larger reserve force to strike back in a big counteroffensive. By means of the counteroffensive, he intended to force the Allies to settle for a negotiated peace, whereupon he might give his full attention to the Soviet Union.

A strong factor in Hitler's confidence was his belief that the Allies had outrun their supply lines. In this he was correct, though General Eisenhower and his subordinates hoped to get past the West Wall and establish bridgeheads over the Rhine before a pause became imperative. Eisenhower's problem was not a shortage of supplies on the Continent but a task of getting them to the forward troops, who in some cases were more than 500 miles from supply depots. The problem grew out of the explosive nature of the advance through France and the decision to forego a pause at the Seine, which had denied the supply services time to build an orderly logistical structure. Despite such extraordinary measures as the establishment of a one-way truck route called the Red Ball Express, the supply troops simply could not keep pace. For five days at the end of August, Patton's Third Army came to a complete halt at the Meuse for lack of gasoline. General Hodges of the First Army had to halt one corps for the same reason, and one British corps had to stop for more than a week to enable its trucks to supply the rest of the Second Army. Some idea of the immensity of the supply requirements is apparent from the fact that each division required 600 to 700 tons of supplies per day and that artillery and mortars expended ammunition at the rate of 8,000,000 rounds per month, almost as much as the entire American Expeditionary Force expended (10,000,000 rounds) in World War I.

Operations in the Netherlands and on the Franco-German Border.—In the light of the supply problems, Eisenhower's continued determination to proceed into Germany on a broad front seemed to two of his subordinates a mistake. Montgomery insisted vehemently that Eisenhower should concentrate all his resources behind one part of the front, preferably in the north, and make one sustained drive all the way to Berlin. General Patton resisted the idea just as strongly and insisted instead that, if given proper support, his Third Army could gain the Rhine in a matter of days. Though Eisenhower rejected both arguments, he nevertheless sanctioned a plan put forward by Montgomery to use 3 airborne divisions

to help the British Second Army across three major water obstacles in the Netherlands: the Maas (Meuse), Waal, and Lower Rhine (Neder Rijn) rivers. This accomplished, Montgomery might outflank the West Wall and gain a position from which he might drive into the North German plain to encircle the Ruhr from the north. In the meantime, the Sixth Army Group, using separate supply routes, was to continue through the Vosges to the upper Rhine, the Third Army was to drive into the Saar, and Hodges' First Army was to penetrate the West Wall at Aachen and gain a bridgehead over the Rhine near Cologne (Köln).

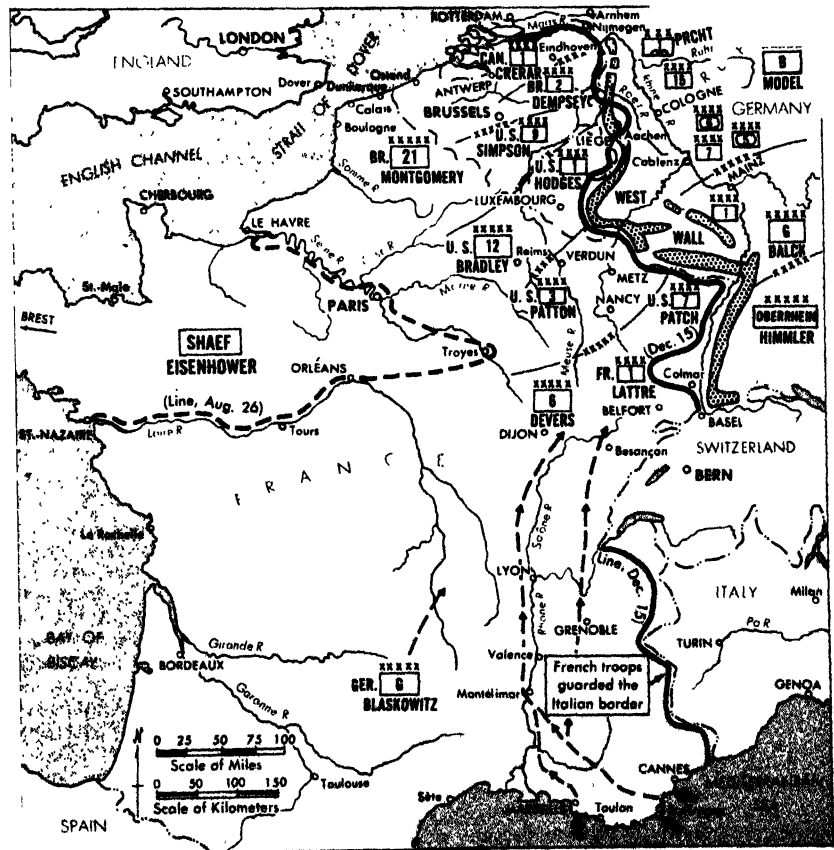

When Montgomery first proposed the airborne-assisted drive through the Netherlands, the Germans had almost no forces in a position to block it. Before the operation could be launched, however, Hitler rushed forward headquarters of the First Parachute Army under Col. Gen. Kurt Student to gather the fleeing troops and build a line along the Dutch canals. He also ordered into position several divisions from a 60,000-man force of the Fifteenth Army, which had escaped entrapment on the Channel coast by ferrying across the Scheldt Estuary after the fall of Antwerp.

The big airborne attack, labeled Operation Market, began on September 17. Under Lt. Gen. Lewis H. Brereton's First Allied Airborne Army, 3 divisions—the British 1st and the United States 82d and 101st—landed near Arnhem, Nijmegen, and Eindhoven in the largest airborne operation of the war. The airborne troops were to seize a narrow corridor 65 miles deep to enable the Second Army, in a companion ground attack called Operation Garden, to pass through and reach the

IJsselmeer (Zuider Zee), thereby cutting off all German forces in the western Netherlands. Though the airborne drops were uniformly successful and achieved full surprise, the British ground column ran into stubborn resistance and blown bridges that created serious delays. Before the ground forces could break through to the British airborne division at Arnhem, the farthest unit from the original front line, the Germans threw in remnants of 2 panzer divisions that had been reorganizing nearby. As the Germans pinned the British airborne troops to a narrow bridgehead north of the Lower Rhine, Montgomery ordered the commitment of a Polish airborne brigade, but to no avail. On September 25–26, the battered survivors (2,000 men out of an original force of not quite 9,000) withdrew to the south bank of the river.

The outcome of Market-Garden in itself would have been enough to demonstrate that the big pursuit was over, but, in addition, all Allied armies had run into trouble. Facing the German Nineteenth Army, which was strengthened by the forested foothills of the Vosges, the Sixth Army Group could make only limited gains. Though the Hitler-ordered counterattack against Patton's south flank was doomed from the start by inadequate strength and hasty mounting, sizable advances by the Third Army were thwarted by a staunchly defended Moselle River line and by old but formidable forts around Metz. Both at Aachen and in the Ardennes the First Army pierced the West Wall in several places, but General Hodges' forces were too greatly extended to exploit the gains. As September passed into October, Allied

Map 11. ALLIES ADVANCE TO THE GERMAN WEST WALL (Aug. 25–Dec. 15, 1944). The American breakthrough at St.-Lo and the Canadian-American near encirclement of the German Seventh and Fifth Armored armies in the Falaise pocket had so disrupted the German linear defense that a general withdrawal was forced. The rapidity of the Allied offensive precluded a German reorganization on the Seine, and the withdrawal continued eastward. By September 15, the United States First Army had reached the West Wall in most of its sector; to the north, Field Marshal Sir Bernard Law Montgomery's troops had reached an east-west line through Antwerp, against stiffening resistance; and to the south the Germans had reformed for a stand on the line of the Moselle River and the Vosges Mountains. It was necessary for the Allies to halt, reform, and prepare for major offensives in the north and south in order to close to the line of the West Wall, preparatory to a general advance to the Rhine. This was accomplished in bitter fighting by December 15, except for the area of the Colmar pocket; a small area east and south of Roermond; and the Roer River dams, which permitted the Germans to flood the lower Roer area at will.

armies everywhere had bogged down. While the logistical situation began to improve with time, the German hold on the banks of the Scheldt Estuary continued to deny the use of Antwerp as a port, and until Antwerp could be opened, no sustained offensive could be maintained. Though Montgomery chafed at the assignment of opening Antwerp, preferring instead to make a new attempt to reach the Ruhr from the corridor opened by Operation Market-Garden, he at last turned his full attention to the task in mid-October. Yet it would be a long time before the first Allied ship dropped anchor at Antwerp. Flooding much of the low lying countryside, the Germans fought tenaciously until November 8, inflicting nearly 13,000 casualties on the Canadian First Army. Because the Scheldt Estuary still had to be cleared of mines, Antwerp did not begin functioning as a port until November 28.

In the meantime, encouraged by a steady though unspectacular improvement in the supply situation, Eisenhower had ordered a new offensive to begin in early November, with the main effort to be made by the First Army around Aachen. General Simpson's Ninth Army, which had been moved forward from Brittany, made a supporting attack on the left, while the Third Army launched a similar thrust from the vicinity of Metz. On November 16, the heaviest air bombardment in direct support of troops on the ground to be launched during the war began east of Aachen in support of the First and Ninth armies (Operation Queen). More than 4,000 planes, including 2,400 heavy bombers, dropped over 10,000 tons of bombs on German defenses and communications centers in an effort to repeat the success of the breakout from Normandy. Unfortunately for the success of the attack, Allied commanders had attempted to cover too broad a target area and, in an effort to avoid repeating the costly errors of bombs falling short in Normandy, had allowed too great an interval between the attacking troops and the bomb line. By the time the ground troops could cross this interval, the Germans had recovered sufficiently to reman their posts.

It took all the rest of November and part of December for the First and Ninth armies to build up their forces along the Roer (Rur) River, in places only 7 miles beyond the line from which the offensive began. Even then the armies were powerless to cross the Roer, for a series of dams on its upper reaches remained in German hands and might be blown to flood the valley and trap any force which had moved east of the river.

Farther south the French First Army and the United States Third and Seventh armies had made greater gains, though the Germans still yielded ground only grudgingly. By the end of the first week in December, the two armies of the Sixth Army Group had compressed the Germans into a large bridgehead west of the Rhine based on the city of Colmar (the so-called Colmar pocket), and the Third Army had reached the West Wall along the face of the Saar. The British and Canadians meanwhile had cleared all of the Netherlands south and west of the Maas.

GERMAN COUNTEROFFENSIVE AND ALLIED DRIVE TO THE RHINE

Battle of the Bulge.—This was the situation on December 16, Hitler struck back with his long-planned counteroffensive. From the breach created in Allied lines it came to be known

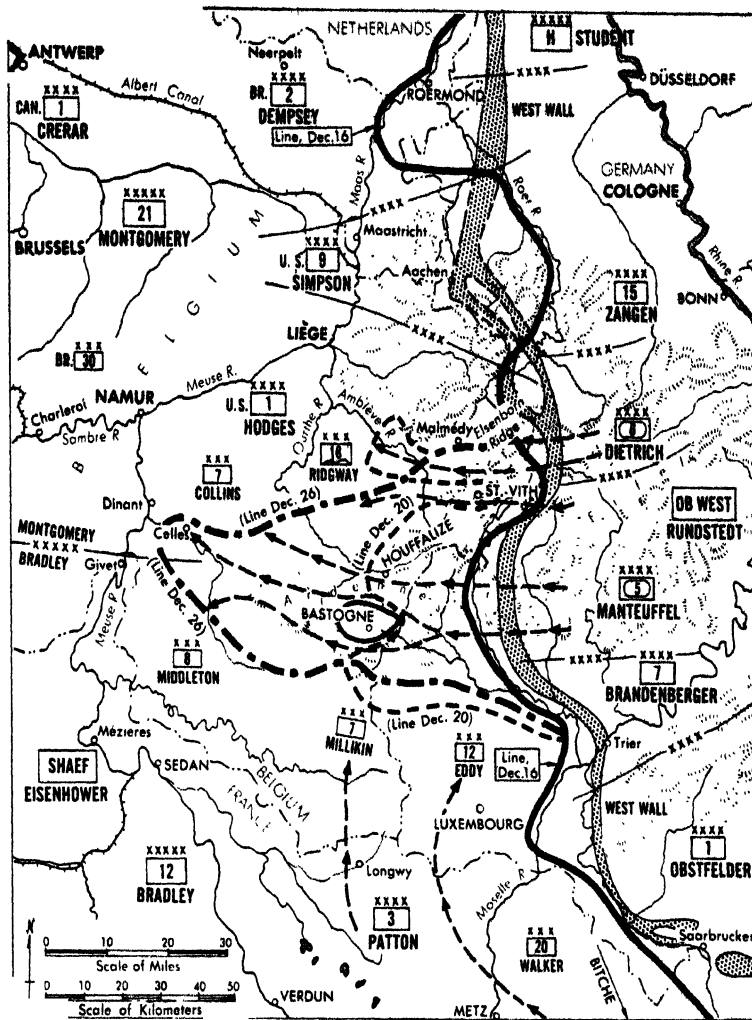

as the Battle of the Bulge. Assisted by the West Wall, excellent defensive terrain along the frontier, and the Allied supply problems, the Germans through the fall had succeeded not only in holding Eisenhower's armies to relatively minor gains; they had at the same time massed behind the front a strong reserve centered around 11 panzer divisions. Hitler intended to strike with this force through the forested Ardennes, cross the Meuse River, and recapture Antwerp, thereby trapping four Allied armies in the north. Though his field commanders deemed the plan too ambitious for the available resources, Hitler would sanction no alterations. After the manner of the German armies in World War I, he took extraordinary precautions to maintain secrecy. Only a handful of commanders knew of the plan until a short while before the target date. Though Allied intelligence early noted the assembling of strong armored forces near Cologne, most intelligence officers assumed that these were intended to counterattack once the First and Ninth armies had crossed the Roer. Fog and snow in the wooded Eifel region opposite the Ardennes successfully cloaked final moves to attack positions. A small force of English-speaking Germans in Allied uniforms early began to infiltrate the lines, later to cause confusion out of proportion to the size of the group. Then, before dawn on December 16, three German armies totaling 25 divisions struck along 70 miles of Ardennes front thinly manned by 6 American divisions.

Making the main effort to seize vital roads in the north, the Sixth Panzer Army under Gen. Sepp Dietrich almost immediately ran into unyielding resistance from the 2d and 99th divisions of Gerow's 5th Corps. For three crucial days these divisions denied the high ground of Elsenborn Ridge and control of the roads Dietrich needed. Only an armored task force called Kampfgruppe Peiper from its commander, Lt. Col. Joachim Peiper, broke through. Committing terrible atrocities against civilians and soldiers, including the murder of close to 100 American prisoners near Malmédy, this force drove more than 15 miles before American reserves bottled it up and clearing weather enabled fighter bombers to wreak havoc on its tanks.

Progress was better in the center, where the Fifth Panzer Army under Gen. Hasso von Manteuffel struck the 8th Corps. Here the American lines were particularly thin, manned by a division seriously understrength from hard fighting in the November offensive and by an inexperienced division only recently arrived from the United States. Everywhere the Germans broke through but at terrible cost. Rallying from early surprise, the Americans threw in small units at critical points to deny the Germans villages, defiles, bridges, and road junctions. Local commanders committed engineer units, quartermaster troops, and even cooks and bakers to the firing line. Though the Germans encircled and captured two thirds of the inexperienced 106th Division in front of the road center of St.-Vith, the division had held its ground long enough for the Twelfth Army Group commander, General Bradley, to rush the 7th Armored Division from a reserve position to hold the town.

The most notable German success occurred south of St.-Vith, where by nightfall of the second day two panzer corps of the Fifth Panzer Army had broken into Luxembourg and headed toward the Meuse River by way of the Belgian road center

Map 12. GERMAN COUNTERATTACK: BATTLE OF THE BULGE (Dec. 16, 1944-Jan. 31, 1945). As the Allies threatened the West Wall, Adolf Hitler gathered his last major reserves for a counter-offensive. It was launched in the weakly held Ardennes sector, with the object of driving to Antwerp, splitting the Allied armies, and destroying those in the north. Through surprise it had great initial success, but it was stopped short of the Meuse River because of quick reinforcement of the weak Allied front, insufficient German logistical support to sustain such an extensive drive, and continuous pounding by Allied aircraft. The Allies attacked against the base of the penetration from the north and the south in an effort to trap the German forces, but most of them escaped. The original line was regained by the Allies by January 31, and they then resumed preparations for the crossing of the Rhine and the final offensive in Germany. The net result of Hitler's Ardennes counter-offensive, in which his general reserve was subjected to defeat, was to hasten the end of the war.

of Bastogne. In the meantime, however, General Eisenhower had alerted the only American divisions immediately available as theater reserves, the 82d and 101st Airborne divisions under Maj. Gen. (later Gen.) Matthew B. Ridgway's 18th Airborne Corps. He ordered the divisions to Bastogne, there to be used as the First Army commander, General Hodges, directed. Thus, unknown to either adversary, a race was on for Bastogne.

Eisenhower directed also that Patton call off his offensive against the West Wall in the Saar and turn to strike the south shoulder of the German penetration. Here the German Seventh Army under Gen. Erich Brandenberger, charged with holding the south flank, lacked sizable armored components and had failed to keep pace with the Fifth Panzer Army's advance. As the armored penetration deepened, Eisenhower put all forces north of the bulge under Field Marshal Montgomery, while Bradley retained command of the forces to the south. Montgomery hurried troops of his own 30th Corps to reserve positions west of the Meuse to forestall a German crossing of the river.

As the 82d Airborne Division neared Bastogne, General Hodges ordered the division and headquarters of the 18th Airborne Corps to continue

northward to help support the north flank of the penetration west of Elsenborn Ridge. The 101st Airborne Division, arriving later, was to defend Bastogne. As night came on December 18, the advance guard of the Fifth Panzer Army's panzer columns approached Bastogne, where remnants of American units were holding outposts until the airborne division arrived. By the next morning, American positions were strong enough to discourage the Germans from assaulting the town immediately. Surrounding Bastogne, the bulk of the panzer units continued toward the Meuse, but at critical points they continued to meet small American delaying detachments that demanded a high price in casualties and time before the Germans might pass. The panzer divisions still were a long way from the Meuse when, on December 23, the winter skies cleared, and waves of Allied fighter bombers roared to the attack.

On Christmas Eve an armored spearhead got within 3 miles of the Meuse at Celles but there encountered the United States 2d Armored Division, which had hurried down from the north. In a pitched battle on Christmas Day, the American armor annihilated one German regiment and threw back what proved to be the high-water mark of the counteroffensive. The 2d Armored Division was part of General Collins' 7th Corps which,

along with the 18th Airborne Corps, General Hodges had committed to hold the north flank of the German bulge. There Dietrich's Sixth Panzer Army, finally despairing of taking Elsenborn Ridge, had followed the path of Kampfgruppe Peiper and then tried again to swing northwestward to get across the Meuse. When continued German attacks at St.-Vith at last forced the 7th Armored Division to abandon that town on December 21, additional roads were opened to reinforce Dietrich's thrust. Nevertheless, by December 25 Hodges had formed an unyielding line north of the Amblève River with 8 divisions reinforcing the 2 divisions that still held Elsenborn Ridge. The use here for the first time of a newly developed proximity fuze for artillery shells that exploded them in the air before contact materially aided Hodges' defense. At Bastogne, meanwhile, the Germans had launched an all-out effort to take the town. On December 22, when German emissaries entered the American perimeter with a surrender ultimatum, the American commander, Brig. Gen. (later Gen.) Anthony C. McAuliffe, gave his famous response, "Nuts!"

It was the next day, December 23, that the skies cleared and waves of cargo planes began to resupply the beleaguered troops in Bastogne. The fighting all around the perimeter was fierce, but morale remained high. Then, on the day after Christmas, the 4th Armored Division of Patton's Third Army, having begun to attack four days earlier, broke through to Bastogne from the south. Hard fighting remained before the narrow corridor into the town could be expanded, and the Germans continued through Jan. 3, 1945, to try to take Bastogne, but without success. Having relieved Bastogne, Patton's 3d Corps continued to attack northeastward from the town toward Houffalize in the center of the bulge. Collins' 7th Corps of the First Army began a similar attack toward Houffalize from the north on January 3. The object was to rejoin the First and Third armies and to trap any German units still remaining in the western tip of the bulge. Through intense cold and deep, crippling drifts of snow the American troops fought slowly toward a juncture. At last, on January 16, patrols of the two armies linked at Houffalize. Hitler in the meantime had reluctantly concluded that his bold counteroffensive had failed. On January 8, he ordered Dietrich's Sixth Panzer Army to fall back to a line close to the German frontier and the rest of his forces to evacuate the tip of the bulge. Thus the American pincers which closed on January 16 failed to trap sizable numbers of German troops.

Meanwhile, the 5th Corps of the First Army and the 12th Corps of the Third Army had broadened the Allied offensive to the east and headed toward St.-Vith. At almost the same time, on January 12, the Russians began a new offensive on the eastern front that ripped great holes in the German line. On January 22, Hitler ordered the depleted Sixth Panzer Army to begin moving from the western front to reinforce the east. By the end of January, the American First and Third armies had reached the German frontier to reestablish the line that had existed before Hitler's armies came out of the mists of the Eifel. The net effect of the counteroffensive was to delay Allied attacks about six weeks at a cost to the Germans of more than 100,000 casualties, 600 tanks and assault guns, and about 1,600 planes. The Americans incurred approximately 76,000 casualties.

In launching the counteroffensive, Hitler had counted on surprise and overwhelming initial strength to pierce the thinly manned American positions swiftly and gain the Meuse by the third day. He had failed to reckon on the tenacity of the American troops. Though broken into small, disorganized units, the Americans had continued to fight with élan and determination. Hitler had failed to reckon also on the swiftness with which the Allies could move to counter the early blows. The First Army alone in the first week of the attack moved 248,000 troops and 48,711 vehicles. In one day, December 17, 60,000 men were moved into the Ardennes. Speedy American removal or steadfast defense of major supply depots also hurt the Germans, for in the effort to maintain secrecy most German supplies had been held far back behind the Rhine. After the skies cleared, Allied aircraft scored telling blows on supply convoys treading the icy, winding roads of the Eifel. Though the Luftwaffe mustered surprising strength (as many as 600 sorties a day during the first two weeks), the German planes were overwhelmed by Allied fighter strength. On New Year's Day, in a major attack, approximately 800 German planes caught Allied aircraft on the ground on airfields in Belgium and the Netherlands, but even though they destroyed or damaged 260 planes, the Germans themselves lost 200. These losses the depleted Luftwaffe could ill afford.

The Battle of the Bulge was the greatest pitched battle on the western front in World War II. A total of 29 German and 33 Allied divisions (mainly American) participated. The Germans had created a short-lived bulge in American lines 70 miles wide and 50 miles deep at its westernmost point. They had paid for it with the loss of priceless reserves that left the German Army brittle, ready prey for annihilation once the Allies resumed their offensive in earnest.

Operation Nordwind.—In planning for a winter counteroffensive, Hitler at one point had considered striking not in the Ardennes but in Alsace. When the Ardennes counteroffensive began to go badly and it became obvious that Eisenhower was moving divisions from the south into the Ardennes, he looked again toward Alsace. As the plan was finally determined, the German First Army was to attack southward from the West Wall through Bitche and the Wissembourg gap (the latter the site of first German success in the Franco-Prussian War of 1870), while the Nineteenth Army launched a subsidiary thrust northward from the bridgehead around Colmar. The two attacks, under the code name Nordwind, were to link east of the Saverne gap, trapping that part of the United States Seventh Army in northern Alsace and recapturing Strasbourg, a city politically important to the French.

The attacks began just before midnight on December 31, but this time Allied intelligence had determined what was in the offing. The thrust from the Colmar bridgehead gained little ground, and the attack through Bitche was stopped after two days of fighting. But the main force moving through the Wissembourg gap made such gains that General Eisenhower seriously contemplated falling back to a stronger line in the foothills of the Vosges, abandoning Strasbourg. To this the French commanders and the French government reacted with such vehemence that Eisenhower reconsidered. By January 25, the Germans had been stopped with the loss only of

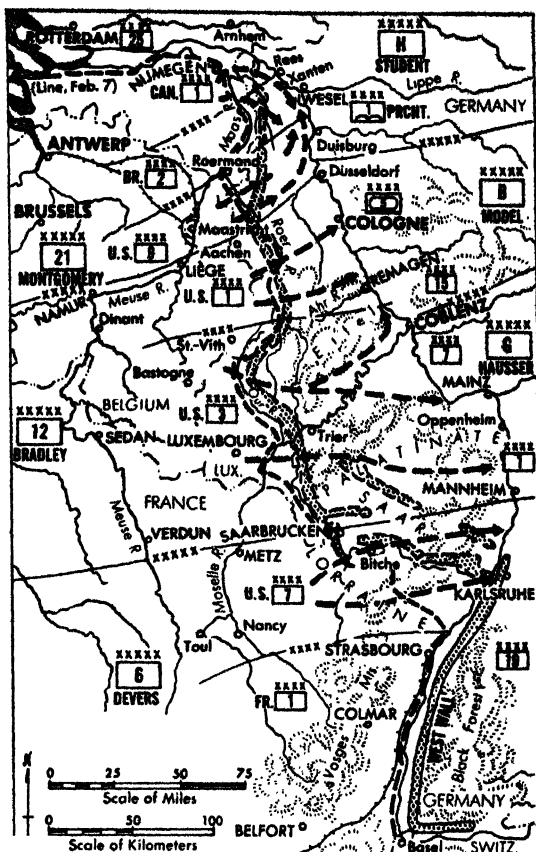

the northeastern corner of Alsace as far south as the Moder River, at the closest point still 12 miles from Strasbourg.

On January 29, the Allied armies in Alsace swung over to the offensive. A week later, United States and French units linked in the center of the Colmar pocket. As the Germans began withdrawing to the east bank of the Rhine, French and United States forces finished clearing the pocket on February 9. The Seventh Army began a drive just over a week later to clear northeastern Alsace and at month's end established a foothold on German soil beyond the Saar River. Though troublesome, Operation Nordwind had failed either to divert any American troops from the Ardennes or to forestall the movement of any units earmarked for that area. The Germans incurred 25,000 casualties; the Americans, 16,000.

Drive to the Rhine.—As the First and Third armies eliminated the last of the bulge in the Ardennes at the end of December, General Bradley wanted to continue the attack through the Eifel south of the dams on the upper Roer River, which were still in German hands. Field Marshal Montgomery, on the other hand, demanded that the main effort continue to be made in the north and that Bradley's forces be halted to provide strength there. Though Eisenhower declined to stop Bradley's drive altogether, he too believed the main effort should continue in the north along the most direct route to the Ruhr industrial area. Leaving the Ninth Army under Montgomery's command, he moved divisions from Bradley's First and Third armies to strengthen the Ninth along the Roer River, northeast of Aachen, and told Bradley to mount an attack to take the Roer dams to prevent the Germans from flooding the river.

In the main offensive the Canadian First Army attacked on February 8 (Operation Veritable) from positions near Nijmegen gained in the airborne attack in September. While the Canadians drove southeastward up the west bank of the Rhine, Simpson's Ninth Army on February 12 was to jump the Roer (Operation Grenade) and gain the Rhine near Düsseldorf, and then turn northward to link with the Canadians. The Second British Army meanwhile was to push eastward between the other two armies. As the Canadians attacked, they ran into the strongest force left to the Germans in the west. This was Army Group H, organized in the fall under General Student with the First Parachute and Twenty-fifth armies. They also encountered mud, age-old enemy of armies, and low-lying ground flooded by an early thaw. Because the First Army failed to take the Roer dams until the Germans demolished one dam and flooded the river, the Ninth Army could not cross the Roer until February 23. Thus the Germans were able to concentrate additional strength against the Canadians. Gains were short and casualties high.

On the other hand, the shift of German strength to the north meant eventual easier going for the Ninth Army. On the eighth day of attack the army gained the Rhine near Düsseldorf and turned to meet the Canadians. In 11 days the Ninth Army drove 50 miles with fewer than 7,300 casualties, while killing approximately 6,000 Germans and taking 30,000 prisoners. The Canadian First Army had incurred 16,000 casualties. Attacking at the same time as the Ninth Army, a corps of Hodges' First Army also jumped the Roer. Designed originally to protect the Ninth Army's flank, the attack was expanded on March

Map 13. ALLIED ADVANCE TO THE RHINE (Feb. 8–March 21, 1945). Preliminary operations to clear the Colmar pocket and the Roermond triangle and to capture the Roer River dams were generally completed by February 8, and the Allied main operations for the advance to the Rhine then began. They were eminently successful, and by March 21 the Allies occupied the west bank of the Rhine, except for the section to the south between Mannheim and Karlsruhe. During the drive the United States First Army seized a bridgehead across the Rhine at Remagen, and the United States Third Army gained one at Oppenheim. These penetrations on the east bank upset German plans for the defense of the Rhine. Their stubbornness in defending the west bank of the river cost them heavy casualties which, in this final phase of the war, they could not afford.

1, and swept rapidly toward the Rhine against disintegrating resistance. Troops of the 7th Corps entered Cologne on March 5. Over the protests of his field commanders, Hitler steadfastly refused to order a strategic withdrawal behind the Rhine.

Chafing to get into the fight in force, Patton had managed to continue limited offensives in the Eifel that took Trier (March 1) and pushed 15 miles inside the German border. On March 3, the Third Army began a major attack to gain the Rhine north of Coblenz (Koblenz) and link with the First Army along the Ahr River south of Remagen.

As a combat command of the First Army's 9th Armored Division approached Remagen on the afternoon of March 7, the men were astonished to see the Ludendorff railroad bridge across the Rhine still standing. Confused by overlapping command channels and by the recent transfer of the general who had been in over-all charge, the

Germans at the bridge had delayed too long in demolishing it. As a United States platoon rushed toward the bridge, the Germans set off demolition charges, but they failed to do more than damage it. In the face of small-arms fire from the east bank, the American riflemen charged across the bridge. In a matter of minutes the Allies had a bridgehead beyond the Rhine. Though General Eisenhower had intended no crossing in the Remagen area, he acted quickly to exploit the coup. Three days after the first crossing, the First Army had 1 armored and 3 infantry divisions across the river. Denuding other parts of the Rhine front, the Germans launched savage attacks against the bridgehead, but to no avail. Though the Luftwaffe tried time after time to destroy the bridge from the air, it stood until March 17. Weakened by hits from long-range artillery, the Ludendorff bridge collapsed that day, but by then engineers had spanned the river in other places.

Patton's Third Army meanwhile had pierced the Eifel with swift armored thrusts that trapped thousands of Germans and cleared the entire region north of the Moselle by March 11. Patton turned then to jump the Moselle and assist Patch's Seventh Army in sweeping the Saar and the Palatinate. This was accomplished by March 25 at a cost to the Germans of 100,000 prisoners. In the entire battle of the Rhineland, the Germans lost more than 250,000 men. Even before the Saar region was clear, Patton launched a surprise thrust across the Rhine. Shortly before midnight on March 22, the 5th Division sneaked across near Oppenheim against only scattered small-arms fire. Before daylight of March 23, 6 infantry battalions were on the east bank at a cost of only 28 casualties.

With the clearing of the Saar and the Palatinate, Allied armies held the west bank of the Rhine from Arnheim to the Swiss border. Except for fortifications on the east bank from Karlsruhe to Switzerland, the West Wall lay behind. Gone too were the days of painfully slow advances through mud, ice, and snow. And through it all the mammoth aerial campaign continued, turning German cities to rubble. In one day in March, Allied planes flew 11,000 sorties. Though on the German side jet-propelled fighters at last began to take to the skies in impressive numbers, they were too late to change the course of the war. By the end of March, after dropping a record 245,000 tons of bombs during the month, Allied strategic bombers were almost out of targets. The German units that managed to escape to the east bank of the Rhine made an impressive array on paper, but in reality they equaled only about 26 complete divisions. General Eisenhower's forces meanwhile had increased to 85 divisions, 5 of them airborne and 23 of them armored. His total command now numbered 4,000,000 men.

On March 10, soon after loss of the Remagen bridge, Hitler relieved Field Marshal von Rundstedt as commander in chief in the west. In his place he installed Field Marshal Albert Kesselring, former German commander in Italy. But it would take more than a new commander to bring any order out of the chaos that now enveloped the German armies in the west. Army Group G in the south was weakest of all. Army Group B in the center, preoccupied with the Remagen bridgehead, was in no position to stop a major attack to break out of the bridgehead.

Only Army Group H in the north with the First Parachute and Twenty-fifth armies had any real strength left. Committed to protect the vital Ruhr industrial area, even this group was thinly spread.

In contrast to American commanders, Field Marshal Montgomery left nothing to chance in his preparations to put his Twenty-first Army Group across the Rhine (Operation Plunder). Air attacks to isolate the battlefield began two weeks before the target date for the crossing, and the First Allied Airborne Army was assigned to drop 2 airborne divisions in support of the operation. A smoke screen 50 miles long covered the preparations. Behind heavy artillery fires, the British Second Army started crossing the Rhine between Xanten and Rees soon after nightfall on March 23. Before daylight the next morning, the Ninth Army also began to cross the river south of Wesel. The Ninth Army in particular met limited opposition. The army's casualties for the first day were 41 killed, 450 wounded, and 7 missing, surprisingly low for an attack against a defended river line. The airborne divisions—1 United States and 1 British—began landing in midmorning of March 24, and by nightfall both were in contact with British ground troops. By the end of the day the two Allied armies had established a firm bridgehead as deep as 6 miles in places.

VICTORY IN THE WEST

Drive to the Elbe.—The unqualified success in the north was the signal for all Allied armies to begin the victory sweep through Germany. While approving a plan for the Ninth and First armies to encircle the Ruhr, with the former remaining under Montgomery's command, General Eisenhower directed that as soon as the Ruhr was secured, the Ninth Army was to revert to Bradley's Twelfth Army Group. Bradley's armies then were to make the main Allied effort along the Erfurt-Leipzig-Dresden axis to link up with the Russians.

The Third Army began to exploit its Rhine crossing on March 25, and the next day seized a bridge across the Main River near Frankfurt and entered the outskirts of the city. On March 29, the First and Third armies linked their bridgeheads near Wiesbaden. The Seventh Army in the meantime made an assault crossing of the Rhine on either side of Worms before daylight on March 26. Other troops of the army crossed near Mannheim, and on April 1 entered Heidelberg. Alarmed lest the French be denied a major role in the push through Germany, General de Lattre speeded the attack preparations of his First Army, crossed the Rhine before daylight on March 31 near Speyer, and turned southward toward Stuttgart.

The reaction of the German High Command to the advances of the Sixth Army Group was typical of that all along the front. Hitler and his entourage in OKW seemed incapable of comprehending the extent of German losses and reverses. Unable to make additional troops available, OKW insisted nevertheless that Army Group G counterattack northward to cut off the Sixth Army Group columns. When this proved impossible, OKW relieved the group commander. Hitler had already tried to form a *Volkssturm* (People's Army), but in almost every case these untrained, ill-armed, poorly equipped troops put up little fight. He called now for the formation

of an underground army of "Werewolves" to fight the invading armies by any and all methods. It was a dramatic appeal, but it produced few tangible results.

In the north, Simpson's Ninth Army and Hodges' First Army swept rapidly toward a juncture on the east face of the Ruhr industrial area near Paderborn. The drive gained speed from the fact that the Army Group B commander, Field Marshal Model, had disposed his remaining defenses facing southward against the Remagen bridgehead and thus was ill prepared for the First Army's push to the east. What was more, the First Army drive severed all contact between the forces of Army Group B and Army Group C. Similarly, Army Group H north of the Ruhr was powerless to stop the eastward push of the Ninth Army. Though the commander, General Student, begged permission to fall back behind the Weser River and to withdraw forces from the Netherlands to help build a new line, Hitler and OKW rejected the requests. Armored spearheads of the two American armies met at Lippstadt, 17 miles west of Paderborn, on April 1 to complete what General Eisenhower called "the largest double envelopment in history." Caught in the Ruhr pocket was all of Army Group B with its Fifth Panzer and Fifteenth armies and part of Army Group H's First Parachute Army.

After attempting without success to break out of the pocket, first to the north and then to the south, Field Marshal Model settled down to fight to the end, hoping thereby to tie up as many Allied troops as possible. But the end was not long in coming. On April 14, the Americans cut the pocket in two. Two days after the eastern half collapsed, and on April 18 all the remaining garrison surrendered. The final count of prisoners exceeded 325,000. Model himself was reputedly a suicide. A new United States army headquarters, the Fifteenth under General Gerow, former 5th Corps commander, came forward to supervise the final mopping up, while the First and Ninth armies continued to the east.

As all Allied armies spread out over Germany, their advances exceeded even those of the great pursuit across France. Drives of 35 to 50 miles a day were not uncommon. Armored divisions usually led the way, but infantry units too, the men mounted on attached tanks or tank destroyers or riding trucks normally used to tow artillery, made rapid dashes. Many towns and villages lay undefended. All that stood in the way of capturing others were roadblocks hastily constructed of heavy logs. Demolished bridges caused the greatest delays, but with the Germans able to form no solid line even behind sprawling streams like the Weser, infantrymen quickly paddled across in assault boats to form a bridgehead while engineers often in less than half a day constructed pontoon bridges that tanks and other vehicles might use. White flags raised by an apathetic and supine citizenry flew from every building. In most cases the Germans put up a half-hearted resistance and then merely waited for the Allied flood to roll over them. In others some local commander might instill his troops with special bravado and bring on a fierce little engagement in the midst of an otherwise unimpeded advance. This happened at Kassel and left the city in ruins. It happened also at Heilbronn on the Neckar River, where

the Seventh Army required a week to reduce the city. It happened too in the Harz Mountains, where contingents of the First Army also found themselves involved for a full week in a real war again.

On the *Reichsautobahnen*, the superhighways with which Hitler had laced the country for moving his military forces, Allied columns roared up all four lanes, while crowds of dejected German prisoners or ragged but exuberant slave laborers of almost every nationality in Europe marched westward down the median strip. Some units overran vast caches of money and works of art looted by the Nazis from all corners of occupied Europe. Others came across walking skeletons who somehow had survived the Nazi concentration camps and mute but grim evidence of human extermination factories. Supplying the far-ranging motorized columns was a tremendous, fantastic task. The most critically needed supplies—gasoline, rations, and ammunition—usually came in by cargo planes to newly captured airfields. Heavily laden trucks with headlights ablaze in disdain for whatever might remain of the Luftwaffe roared through the night on the autobahns. Trucks often had to make 700-mile round trips to railheads along the Rhine. The first two rail bridges built across the river were opened on April 8 at Wesel and on April 14 at Mainz.

In the north the British Second Army bridged the Weser on April 5 and reached the Elbe by April 24. Despite stiff resistance along the Dortmund-Ems Canal, a column on the British left advanced to Bremen by April 20, there to fight a week-long battle against a group of diehard defenders. The columns on the right jumped the lower Elbe on the last two days of April, and on May 2 took Lübeck without opposition, thereby cutting off the peninsula of Schleswig-Holstein and Denmark. The great port of Hamburg surrendered the next day, also without a fight.

The Canadian First Army, driving to cut off the Germans in the Netherlands, engaged in some of the heaviest fighting of all during the first few days of April. From a Rhine bridgehead near Emmerich one column established a bridgehead over the Ems River on April 8, and then ran into one sharp fight after another en route to the naval bases at Emden and Wilhelmshaven. To the west another column driving due north from Emmerich quickly reached the North Sea, cutting what remained of German forces in the northeastern Netherlands into ineffective pockets. Still a third force farther west jumped the Lower Rhine on April 12, cleared Arnhem two days later, and reached the IJsselmeer on April 18. Four days later, Allied commanders, all too aware of the misery already besetting the Dutch people for lack of food, suspended attacks on the promise of the German high commissioner for the Netherlands, Arthur Seyss-Inquart, that he would avoid wholesale flooding of the low-lying country. After a meeting between Seyss-Inquart and Eisenhower's chief of staff on April 30, the Allies began a program to deliver food and supplies to the hard-pressed Dutch, but the Germans in the Netherlands refused to surrender so long as the German government had not capitulated.

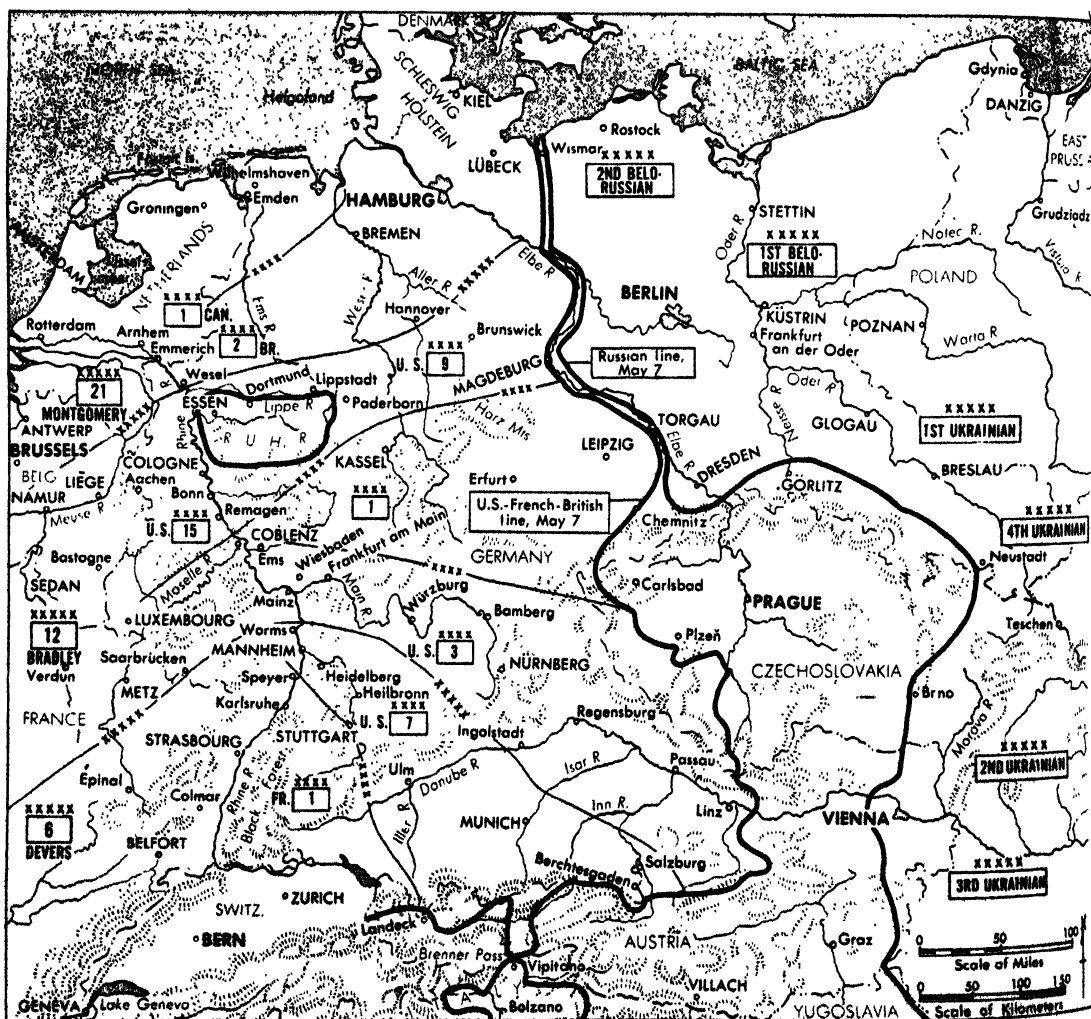

In the Allied center troops of the First and Ninth armies were already on their way to the Elbe even before the final capitulation in the

Ruhr pocket. Armored spearheads of the Ninth Army reached the river near Magdeburg on April 11, and the next day established a bridgehead less than 75 miles from Berlin. The Germans reacted stiffly, even calling in the almost defunct Luftwaffe in troublesome numbers, and forced abandonment of the bridgehead on April 14, but a second bridgehead established the preceding day held fast. This bridgehead constituted no more than a threat, for by this time General Eisenhower had abandoned any idea of driving on Berlin. Since mid-March, Soviet forces had stood on the Oder River, only 28 miles east of the capital, with the apparent ability to take it whenever they chose. In view of this situation, Eisenhower decided to concentrate instead on defeating the German forces in central Germany and on driving into the south where rumors picked up by Allied intelligence seemed to indi-

cate that the Germans were in a last-ditch defensive position in the Alps, the so-called National Redoubt. The Ninth Army was to halt at the Elbe, Eisenhower directed, and the First Army at the Mulde, a tributary of the Elbe, there to await contact with Soviet armies from the east. The First Army took Leipzig on April 18. Already an armored division had bypassed the city to reach the Mulde River. Patrols sent out by both the First and the Ninth armies made contact with forward Soviet units on April 25, while the first formal meeting between United States and Soviet divisional commanders took place near Torgau on the following day.

Meanwhile, the Third Army had pressed on to the Czechoslovakian border. With the First and Ninth armies established on their final objectives, Eisenhower directed the Third Army to sidleslip southward for drives into Czechoslo-

Map 14. COLLAPSE OF GERMANY (March 21–May 7, 1945). The first Allied objective in the crossing of the Rhine was to encircle the rich industrial Ruhr. Field Marshal Sir Bernard Law Montgomery was scheduled to make the main attack in the north, and Gen. Omar N. Bradley a secondary attack to the south. The spectacular successes of Bradley's Twelfth Army Group, however, altered the Allied plan so that Bradley was to make the main attack. On April 1, elements of the United States Ninth and First armies met at Lippstadt to complete the encirclement. By April 18, the Ruhr had been captured, and the Germans had lost 325,000 men and vast stores of supplies and equipment. Meanwhile, the general advance continued to the Elbe, while the United States Third Army struck for Vienna and the Sixth Army Group for western Austria and the Brenner Pass. On April 25, American and Soviet forces met at Torgau. When the Germans surrendered on May 7, the Allied forces had advanced to the lines shown.

Nürnberg before and after the war. vakia, Bavaria, and Austria close beside the Seventh Army. The attack picked up momentum on April 22 and began to make the usual rapid gains at extremely low costs in men. One day, for example, the entire Third Army lost only 3 men killed, 37 wounded, and 5 missing while taking 9,000 German prisoners. Breaking through hastily improvised defenses on the Isar and Inn rivers, contingents of the Third Army on May 4 seized Linz, Austria. Others pushed into Plzeň (Pilsen), already in the hands of Czech partisans.

The two armies of General Devers' Sixth Army Group meanwhile had swung southeastward from their Rhine bridgeheads to sweep to the Swiss border and eventually to enter Austria and link with Allied forces in northern Italy. In addition to a hard fight at the Neckar, troops of the Seventh Army had to battle three days for Nürnberg but took the city on April 20. The French swept through the Black Forest on the east bank of the Rhine, and on April 22 took Stuttgart. As the Seventh Army headed into southern Bavaria and the Austrian Tirol to forestall any establishment there of a National Redoubt, both armies crossed the Danube on April 22. Munich (München) fell on April 30 and Salzburg on May 4, and with the aid of Austrian partisan guides a column pushed to the Brenner Pass on the same day. Berchtesgaden, site of

Hitler's mountain retreat, also fell on May 4. The myth of a National Redoubt exploded. Nowhere was there evidence that the Nazis had made preparations for a last-ditch stand.

End of Hitler.—The precise time when Hitler realized that the end was near is hard to place, but by mid-April it was clearly apparent to him that Allied and Soviet armies soon would split Germany in two. Reserving for himself the right to command in whichever part of Germany he happened to find himself when the split came, he designated Admiral Doenitz, head of the German Navy, to command in the north should the führer be in the south. Similarly, he designated Field Marshal Kesselring to command in the south should he himself be in the north.

By April 22, with Berlin under direct attack from the Soviet Army since April 16, Doenitz, Goering (heir designate to Hitler's post), and most other ranking officials had left Berlin for either the south or the north. Hitler and his military staffs were about all that remained. The führer apparently had high hopes of prolonging the war indefinitely until April 22, when a counterattack which he had ordered to strike the Russians at Berlin from the north failed to materialize. From this point he vowed to stay in the capital, eventually to kill himself rather than to fall into the hands of his enemies.

Learning the next day of Hitler's decision to stay in Berlin, Goering assumed that it was time he took control of the government. When he radioed for instructions, saying that if he received no answer during the day of April 23, he would take charge, Hitler considered the act treasonable. He promptly had Goering arrested. By the end of April, all concerned had to admit that every effort to relieve Berlin had failed, and that the city was facing its final fight. Hitler himself, having composed a will designating Doenitz his successor as head of the German state and supreme commander of the armed forces, committed suicide.

German Surrender.—The possibility of large-scale but piecemeal surrender had been growing since mid-April, but because the Russians were suspicious lest the Germans make peace with the Allies while continuing to fight the Soviet armies, the Allies rejected most overtures. As early as April 23, Heinrich Himmler, head of the *Waffen-SS*, an elite ancillary force of the German Army, offered to arrange a surrender on the entire western front, but the heads of Allied governments replied that unconditional surrender on all fronts, made in agreement with the Allies and the Soviet Union, was the only acceptable course.

Aware of the agreement between the Western Allies and the Soviets, Admiral Doenitz nevertheless hoped to save as many German troops as possible from falling into the hands of the Soviet Army. When the Allies on April 29 accepted the surrender of German forces in Italy to become effective on May 2, he began to explore the possibility of other piecemeal surrenders. This led on May 4 to the surrender of all forces in the north, including Denmark and the Netherlands, to Montgomery and the Twenty-first Army Group, though the terms stipulated that the capitulation would be superseded by any general instrument of surrender later to be signed. The next day, a similar surrender occurred in the south, where Army Group G capitulated to the Sixth Army Group.

A German representative authorized to open negotiations for all remaining forces in the west arrived at General Eisenhower's headquarters in Reims on May 5. Recognizing that the German

scheme was to gain time in which to bring troops facing the Russians into the western zone, Eisenhower informed Moscow that he had no intention of accepting surrender unless it included simultaneous surrender to the Soviets. The Russians in turn authorized Maj. Gen. Ivan Susloparov, already at Eisenhower's headquarters, to act for them. The negotiations began in the late afternoon of May 5. When General Eisenhower made it known that unconditional simultaneous surrender on all fronts was the requirement, the head of the German delegation wired Doenitz for approval. The admiral and those around him were shocked. Doenitz hastily sent General Jodl, head of the OKW operations staff and a strong opponent of surrender in the east, to continue the negotiations at Reims.

When Jodl arrived, he found Eisenhower unyielding. Unless the Germans agreed quickly to surrender, Eisenhower said, he would break off all negotiations and seal the western front to prevent the further westward movement of German troops and civilians. Even Jodl, steadfast opponent of over-all surrender though he was, was impressed. He telegraphed Doenitz for permission to sign. The Germans signed at 2:41 A.M. on May 7. The next day, May 8, the Allied chiefs of staff designated as V-E (Victory in Europe) Day. A second surrender ceremony, with ranking Russians in attendance, took place in Berlin on May 9.

Accomplishments and Cost.—As hostilities came to an end, the German war machine and the German nation were crushed to a degree never before experienced in modern times. With the prior surrender of Army Groups B, G, and H and with the steamroller advance of the Soviet armies, no organized military units remained at the time of the over-all surrender except in Norway and in Czechoslovakia and the Balkans. These were incapable of more than a week or two of resistance even had they chosen to prolong the fight. Though some jet fighter aircraft remained, the Luftwaffe was too demoralized even to make a final suicidal effort. What was left of the German Navy lay helpless in the captured northern ports. Hitler's Germany was prostrate, beaten by powerful Soviet armies and by an Allied force that at war's end totaled

Allied and German representatives prepare to sign the surrender document at Reims on May 7, 1945. On the far side of the table, from left to right, are Lt. Gen. Sir Frederick E. Morgan, Maj. Gen. François Laurent Sevez, Adm. Sir Harold Burrough, Lt. Gen. Walter Bedell Smith, Maj. Gen. Ivan Susloparov, Gen. Carl Spaatz, and Air Marshal Sir James M. Robb; at the foot of the table are Col. Ivan Zenkovich (foreground) and Maj. Gen. Harold R. Bull. Seated on the opposite side is the German delegation: from left to right, Adm. Hans von Friedeburg, Col. Gen. Alfred Jodl, and Maj. Wilhelm Oxenius.

Map 15. ALLIED OCCUPATION ZONES. At the Yalta Conference in February 1945, the three principal Allied leaders—Franklin D. Roosevelt, Winston Churchill, and Joseph Stalin—finished the assignment of occupation zones in Germany and Austria to the several powers. The map shows the areas assigned. The capitals of Berlin and Vienna were to be jointly occupied by the Americans, British, French, and Russians and governed under four-power commissions. In order to permit access to the isolated American zone, the port and enclave of Bremen were assigned to the United States, with rights of access to the United States zone through the British zone. Each nation had right of access to jointly held Berlin and Vienna. At the Potsdam Conference in July–August 1945, the new Western leaders, Harry S. Truman and Clement R. Attlee, agreed reluctantly to Polish “administration” of the territory in the Soviet zone of Germany as far west as the Oder-Neisse line, as shown. In addition, East Prussia was divided between Poland and the USSR.

4,581,000 men in a balanced air-ground military machine. Under Eisenhower's command on V-E Day were nine armies, 23 corps, and 93 divisions and air strength totaling 17,192 planes. Since D-day in Normandy the Germans in the west alone had lost 263,000 dead, 49,000 permanently disabled, and 8,109,000 captured. Allied casualties were 186,900 dead, 545,700 wounded, and 109,600 missing (some later declared dead and others later repatriated as prisoners of war).

Any analysis of the victory must begin with the stubborn refusal of Britain and the Soviet Union to yield early in the war when the odds against them appeared overwhelming, and it must include the vast contribution by the United States both in manpower and as the arsenal of democracy. United States troops comprised more than two thirds of Eisenhower's command at the end of the war. During the last two years alone, American factories produced for the British 185,000 vehicles, 12,000 tanks, and enough planes to equip four tactical air forces; for the Russians, 247,000 vehicles, 4,000 tanks, and enough planes to equip two tactical air forces; and for the French, all weapons and equipment for 13 divisions and their logistical and air support. Thus, unlike the situation in World War I, when the American contribution was relatively small and merely provided the tilt in the balance of power, the reconquest of western Europe in World War II saw a predominant American contribution.

Though airpower failed to prove the decisive instrument that its more outspoken prewar advocates had predicted, it was a major factor in the Allied victory. The naval role was vital as well, for without control of the sea lanes, Allied power could not have been concentrated in England, and without the landing craft, amphibious doctrine, and fire support provided by Allied navies,

the assaults against the beaches of Normandy and southern France could not have been staged. But it was not until Allied ground troops fought their way to a juncture with the Russians that Germany's will was broken.

Throughout the war, Hitler and much of the German nation put their faith in miracle weapons that never came. Postwar revelations have shown that the Germans had not advanced as far toward an atomic bomb as Allied intelligence had feared. The only spectacular accomplishments in miracle weapons were the V-1 (flying bomb) and the V-2 (supersonic rocket). Between June 1944 and March 1945, when the last of the launching sites were overrun, the Germans fired 18,300 V-1's and 3,000 V-2's, about equally divided between England and targets on the Continent, notably Antwerp. They inflicted 33,400 casualties in England and about 13,000 on the Continent, but never seriously affected the military campaign other than to divert anti-aircraft troops and radar equipment to the defense of London and Antwerp.

In quality of weapons and equipment the greatest Allied advantage over the Germans was in heavy bombers and long-range fighters, an achievement never seriously challenged by the Luftwaffe despite the German development of the first supersonic rocket and the first jet-propelled aircraft. In all cases these came too late to affect the outcome of the war. In artillery, mortars, and machine guns both sides were relatively equal, though a technique of massed artillery fire used by the British and Americans was a noteworthy achievement. The Americans enjoyed some firepower advantage with a semi-automatic rifle, but a German machine pistol widely used in rifle battalions drew the respect of all Allied troops. German tanks throughout the war were superior to the Allied mainstay,

the United States Sherman, both in armor and armament, and the German 88-mm. gun, effective against tanks, aircraft, and personnel, was the World War II equivalent of the French 75. American motor vehicles, particularly the highly serviceable two-and-one-half-ton truck, made the Allies markedly superior in the field of motor transport and were in a large measure responsible for fantastic Allied achievements in the field of logistics. The combined staff system of the United States and Britain provided a unity of command and purpose never approached on the Axis side.

6. German Invasion of the USSR

The summer of 1940, after France had surrendered, found Adolf Hitler in a quandary. He had won three whirlwind campaigns, but the next in logical order, the reckoning with Great Britain, was one for which he had little stomach. By his own admission he was a lion on land but a coward on water, and he began planning for an invasion of the British Isles with scant enthusiasm. At the same time he toyed with other projects: the capture of Gibraltar or the Suez Canal, a landing at Haifa, a North African campaign. None of these was significant enough to resolve any of his major problems: how to dispose of Britain; how to secure the *Lebensraum* (space for living) for which the war was ostensibly being fought; how to end the war on German terms before the United States could arm and intervene; how to deal with the Soviet Union, a "friend" he neither liked nor trusted. Most pressing at the moment was the question of Britain. Poland, Norway, Denmark, the Netherlands, Belgium, Luxembourg, and part of France were occupied, but the British showed no inclination to quit. The more he thought it over, the more Hitler became convinced that the British hoped eventually to find an ally in the USSR. If that were true, then the way to bring the British to heel quickly was to remove their last hope.

GERMAN PLANS AND ATTACK: 1941

Exactly when Hitler decided that he would have to fight the Soviet Union is a moot question. The idea of an inevitable clash between nazism and Soviet communism was one of the least ambiguous tenets of his political philosophy. If, during the period of the Nazi-Soviet Pact, he did not talk about it, he also did not renounce it. On the other hand, it cannot be assumed that Hitler was merely executing part of a pre-conceived program. As in nearly all of his decisions,

there was a progression involving the original idea, a specific strategic concept, events and circumstances that seemed to him to confirm the validity of the first two steps, and, finally, a period in which he developed an unshakable determination to see the enterprise through.

The idea of inevitable conflict with the Soviet Union Hitler had expressed in *Mein Kampf*. In July 1940, the apparent stalemate in the war with Britain brought the Soviet Union to the forefront of his strategic thinking as an inviting target in itself, as the last obstacle to German hegemony on the Continent, and as the lever with which to bring Britain to terms. At the same time, by acting as an equal—even an independent—partner, the Soviet government appeared to confirm the line of thought which he had begun to follow. In June 1940, during the week before the Franco-German armistice, Soviet troops occupied Lithuania, Latvia, and Estonia. The secret protocol to the 1939 pact placed the three Baltic states in the Soviet sphere of influence, but the Russians' timing was a disquieting sign that they intended to take their share of every German victory. At the end of June, the Russians forced Rumania to cede Bessarabia and northern Bucovina to them, a step that brought them closer to the Rumanian oilfields, on which the Wehrmacht was heavily dependent. Then, in July, the Soviet government renewed its pressure on Finland. By treaty Finland was in the Soviet sphere of influence, but in occupying Norway Germany had secured an access route to the Finnish nickel-mining region near Petsamo (now Pechenga) on the Arctic coast, and in July 1940 the German firm I. G. Farbenindustrie signed a contract for the entire output of the Finnish mines.

As early as June of that year, the German Army General Staff was speaking of the USSR as the possible next scene of operations. On July 21, toward the end of a conference regarding the projected invasion of the British Isles, Hitler instructed the commander in chief of the army, Field Marshal Walther von Brauchitsch, to begin planning a campaign against the Soviet Union. Ten days later, on July 31, in another conference concerned mostly with the war against Britain, Hitler declared that a reckoning with the Soviet Union was necessary. He said that he had wanted to proceed with it that fall, but because of the severe Russian winters had decided to wait until May 1941. The operation would have to be swift and final, and he was allowing five months for its completion. Any longer period would involve the army in winter warfare and might give the British and Americans time to intervene. In these two almost casual statements, Hitler, if he had not made an irrevocable decision (and perhaps he had not), at least set a course from which he never later saw any reason to deviate.

On August 1, Col. Gen. Franz Halder, chief of the Army General Staff, described to Gen. Erich Marcks a campaign against the Soviet Union employing two army groups, one striking toward Moscow (Moskva) and the other toward Kiev. He assigned to Marcks the task of developing the details. By August 5, Marcks had completed a plan that called for a main effort directed toward Moscow, a secondary effort in the south in the direction of Kiev, and a subsidiary thrust toward Leningrad. There was still much planning to be done, but the Marcks program did establish

army's concept of Moscow as the outstanding strategic objective.

A visit by Foreign Commissar Vyacheslav M. Molotov to Berlin on Nov. 12-13, 1940, produced the first overt signs of a rift between Germany and the USSR. The purpose of the visit was to discuss the Soviet Union's joining Germany, Italy, and Japan in a four-power alliance. Molotov came armed with demands and complaints. He wanted to know whether Germany intended to honor her treaty obligations with respect to Finland. Lately, in his opinion, the Germans had shown too great an interest in that nation, and the Soviet Union intended to intervene there as it had in the Baltic states. The Soviet government also wanted bases in Bulgaria and control of the Dardanelles. Hitler, on the other hand, talked glowingly of Soviet expansion to the east, into India for instance, and he issued a thinly veiled warning that he would not tolerate further Soviet encroachments in Europe. Concerning Finland, he stated that any new disturbance in the Baltic area would place a heavy strain on German-Soviet relations. The meeting had a definite, if subtle, effect on both partners. The Russians continued to maneuver diplomatically but carefully avoided overt acts. Hitler was thoroughly annoyed at the Russians' display of grasping independence, and he believed that they would not have dared to assert themselves as they had without a secret agreement with the British.

Preparation of Operation Barbarossa.—On Dec. 18, 1940, Hitler signed Führer Directive No. 21, subtitled "Operation Barbarossa." The directive, which was based on the work of several planning groups, was the strategic outline for a campaign against the Soviet Union. It laid down a plan for a two-phase operation. In the first phase the German Army was to engage the Soviet main force as close to the western border of the Soviet Union as possible, cut it up by encircling movements, and destroy it and so prevent the Russians from fighting a delaying action across the vast spaces of their country. The second phase would take the form of a rapid pursuit to a line running north and south from the Volga River to Arkhangelsk (Archangel). The destruction of the Urals industrial area farther east could be left to the Luftwaffe.

The directive divided the German forces into three army groups, two north of the Pripyet (Pripyat) Marshes and one to the south. The northernmost army group would strike toward Leningrad, the one in the center toward Smolensk, and that in the south toward Kiev. The central army group would be the strongest, but after the attack began, it might be required to divert some of its strength to help its neighbor on the north toward Leningrad. Hitler had included this idea over the almost unanimous opposition of his generals, but in a sense he was taking the more orthodox view. Leningrad, Smolensk, and Kiev were situated at nearly equal distances from the frontier; therefore, in the light of the over-all strategy, they should have been taken before the army drove deeply into the interior. The generals, on the other hand, had the better argument. In their opinion the main force had to be directed without any diversions toward the primary objective, Moscow, for it was there that the decisive battle would be fought after the Russians had been forced to concentrate all of the forces they could assemble

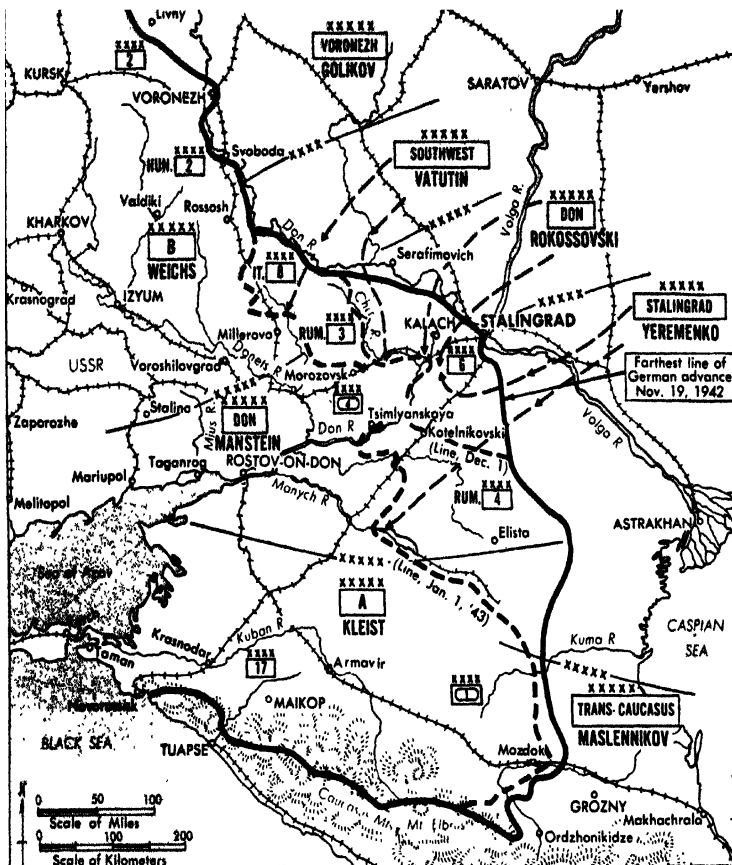

to defend the capital and hub of the country's communications systems.

In the directive, Hitler also stated that Rumania and Finland were to be considered prospective allies in the war against the Soviet Union. Arrangements would be made with both countries in due course. Hitler instructed the German Army of Norway to be prepared to occupy the Petsamo region and to conduct an offensive from Finland to cut the Murmansk (Kirov) Railroad.

Toward the end of January 1941, the Army General Staff completed an operations order that assigned specific missions to the various army groups. Army Group North, commanded by Field Marshal Wilhelm von Leeb, was to attack from East Prussia toward Leningrad. It would place its greatest strength on its right flank and turn to the left, driving the Russian defenders back against the Baltic coast. Army Group Center, under Field Marshal Fedor von Bock, operating north of the Pripyet Marshes, would employ strong tank forces to complete two giant encirclements, one closing near Minsk and the other east of Smolensk. The final decision as to whether this group would continue directly toward Moscow or halt at Smolensk and divert forces to Army Group North could be avoided, since it was contrary to German staff practice to carry definitive planning past the first phase of an operation. Army Group South, commanded by Field Marshal Gerd von Rundstedt, was to attack from southern Poland and Rumania, its flank armies converging on Kiev to trap the Soviet armies in the western Ukraine in a great pocket west of the Dnieper (Dnepr) River. (In March, Hitler became convinced that the southern flank army would not be able to fight its way across the Dniester or Dnestr River; consequently, he assigned to the army on the north the mission of striking toward Kiev and then sweeping southward inside the great bend of the Dnieper.) At a conference on February 3, General Halder summarized the plan for Hitler and informed him that the first echelon of troops was moving into assembly areas behind the frontier. At the close of the conference, Hitler approved the operations order and declared, "The world will hold its breath when Operation Barbarossa begins."

The first starting date set for Operation Barbarossa was May 15. The plans had provided time for a preliminary campaign in Greece, but when Yugoslavia was added to the Balkan campaign after the anti-Axis coup of March 26-27, the timetable had to be revised. Barbarossa was postponed to June 22.

Within the small circle of high-ranking officers and government officials who knew about Barbarossa, opinions varied. Although some of the generals occasionally expressed random doubts, once the planning was well under way, most of them came to share the view of General Halder that the campaign would be completed in 8 to 10 weeks. A notable exception was the military attaché in Moscow, who believed that Soviet industrial capacity, particularly that east of the Urals, was being greatly underestimated. Members of the German Foreign Office contended that so much could be obtained from the Soviet Union by political means that a military conquest was superfluous. The German ambassador to the Soviet Union told Hitler that Joseph Stalin "would give the shirt off his back" to avoid a

Map 22. GERMAN DISASTER AT STALINGRAD (Nov. 19, 1942-Jan. 31, 1943). On Nov. 19, 1942, the Russians launched strong offensives on both sides of Stalingrad. By November 22, the German Sixth Army and half of the Fourth Panzer Army had been encircled and cut off. Pleas to permit an attempt to break out to the rear met with Adolf Hitler's stern order to stand fast. On Jan. 31, 1943, most of the remnants of the Sixth Army, starving and half frozen, surrendered to the Russians (one pocket held out until February 2). In the meantime, the Soviet offensive had intensified on the flanks of the Stalingrad front. It was clear to the Germans that the objective was to drive to Rostov-on-Don and cut off their Army Group Don and Army Group A. The latter, with its front 350 miles southeast of Rostov, was indeed in a dangerous position when the Sixth Army surrendered, thus freeing large Soviet forces for the drive to Rostov.

the German remnants of Army Group B and Army Group Don, which was still endeavoring to hold open Army Group A's lifeline to the west at Rostov.

On January 25, the Russians struck northward once more to hit the German Second Army, which was already withdrawing from Voronezh, and in three days they encircled two of its three corps. Hitler, who for a month had vacillated and discussed counterattacks to relieve Stalingrad, finally had to draw some conclusions. On January 27, he transferred the First Panzer Army to Army Group Don. Since this army was all that could still be removed through Rostov, the rest of Army Group A had to begin withdrawing into a large beachhead on the Taman Peninsula. This maneuver immobilized 400,000 men at a time when the entire southern flank of the eastern front was being shattered.

On January 31, Paulus, refusing to take the hint implicit in his promotion to the rank of field marshal the day before (no German field marshal had even been made prisoner), surrendered the troops that he still controlled in Stalingrad. A pocket around a tractor works in the northern suburbs of the city held out until February 2. On February 6, unwilling to risk another encirclement, Hitler gave Manstein permission to withdraw Army Group Don to the line of the Mius and Donets rivers, from which Army Group A had moved forward in July 1942.

In nine days, Army Group Don executed the retreat to the Mius. Meanwhile, the First Panzer Army moved to the army group's left flank on

the Donets. But the Soviet offensive was still moving forward at full speed. The right flank of Army Group B was forced back to Kharkov, which it lost on February 14-16. A 100-mile gap opened between the flanks of Army Groups B and Don, through which Soviet units struck southward and westward across the Donets. Six Soviet tank corps forming the Popov Group, named for its commander, Col. Gen. Markian M. Popov, moved forward to sever Army Group Don's communications lines. On February 13, it cut the Dnepropetrovsk-Stalino (now Donetsk) railroad, and by February 19 it had reached the Sinielnikovo railroad junction 20 miles east-southeast of Dnepropetrovsk and had begun to turn southward toward Zaporozhe.

On February 12, Hitler had removed the headquarters of Army Group B and divided its front between Army Groups Center and Don, simultaneously redesignating the latter Army Group South. At the same time he ordered 7 divisions transferred from France and Belgium to Army Group South. A week later he ordered Army Group A to begin evacuating troops by air from the Taman Peninsula to reinforce Army Group South; 100,000 troops were transferred by the end of the first week in March.

On February 18, without waiting for the arrival of the divisions from the west or the troops from Army Group A, Manstein initiated a series of maneuvers that were to produce the last German victory of the war. He ordered the headquarters of the Fourth Panzer Army to move to Dnepropetrovsk at about the center of the gap

between the First Panzer Army and the southern flank of the former Army Group B. There, with at first 4 divisions, he began creating a new Fourth Panzer Army. In eight days after February 20, the Fourth and First Panzer armies joined their flanks, trapping the Popov Group between them, and the Fourth Panzer Army closed up on its left to the front west of Kharkov.

At the end of the month warm weather set in, and the question then was whether to continue the advance toward Kharkov at the risk of its being halted by the approaching thaw. On March 7, the weather turned cold, and Manstein decided to proceed. The Fourth Panzer Army moved rapidly to the north, and despite knee-deep mud on all the roads reached Kharkov on March 11. Seven days later, after mopping up the Soviet divisions trapped west of Kharkov, the army carried its advance 30 miles farther north and took Belgorod. Except for several bridgeheads, in which Soviet troops held on doggedly, Army Group South had regained the line of the Donets to Belgorod. Immediately to the north the Russians held a large salient west of Kursk.

Operation Citadel.—For the past three years the coming of spring had heralded new German triumphs. The year 1943 was different. The victory on the Donets that ended the long winter retreat had restored German morale at the front, but not even Hitler deluded himself into believing that the next summer would see the swastika flag replanted on Mount Elbrus or German outposts again looking eastward into Asia from the high bank of the Volga. In the late spring there was an ominous quiet on the eastern front.

Since June 1941, German attention had centered in the east. In the early months of 1943, quite suddenly that, too, changed. Dangers which might have been overcome easily, had the Russian campaign developed according to schedule, threatened on all sides. In January 1943, United States Flying Fortresses staged the first daylight bombing attack on Germany. Thereafter bomb damage, particularly in the Ruhr, mounted alarmingly. A second Stalingrad had been in preparation in North Africa since November 1942. When the British Eighth Army broke through the Mareth Line late in March 1943, it became inevitable. That the British and Americans would follow their victory with an invasion of Italy or the Balkans was certain, and the day of the major test, the landing on the Channel coast, might come within the year.

On the other hand, the failure of Hitler's fanatical resistance doctrine during the winter had produced a substantial bonus. The long retreat from the Don, Stalingrad, and the Caucasus, as well as a voluntary retrograde movement which Army Group Center executed in February and March to shorten its front, had created surplus strength on the eastern front approximately equivalent to two armies. The disastrous winter had also forced Hitler to recall to active duty his tank expert, Guderian, and to appoint him inspector general for armor. By spring Guderian, working with Albert Speer, the minister for armament and munitions, had the new Tiger and Panther tanks coming from production lines by the hundreds. If another offensive in the style of 1941 or 1942 was no longer possible, neither was Germany helpless.

The most profitable strategy seemed to be to consolidate the so-called Fortress Europe and to

exploit the Clausewitzian axiom that defense was the stronger form of warfare. Some of the generals proposed building an East Wall, a permanently fortified line across the USSR, but Hitler disapproved. He did, however, instruct Army Group North to plan an operation to take Leningrad and stabilize the northern flank by joining forces with the Finns. He also began reinforcing the Army of Norway to enable it to occupy Sweden if that country attempted to support Allied operations directed against northern Europe. Nevertheless, after nearly three months' hesitation, he decided that he needed one more big victory in Russia, a victory, as he put it, "that will shine like a beacon around the world." On June 12, he announced that he intended to execute Operation Citadel.

Citadel, a two-pronged attack to eliminate the Soviet salient west of Kursk, had been planned in March to be executed as soon as the ground dried and while the Russians were still off balance from their defeat at Kharkov. Bad weather and various mishaps, as well as Hitler's own uncertainty, had caused repeated postponements. By the time he decided to proceed, the German forces for Citadel were at peak strength, and so, as one of the generals pointed out, were the Russians.

Operation Citadel began on July 5. The Ninth Army on the north and the Fourth Panzer Army on the south struck toward Kursk across the base of the Soviet salient. For three days the attack went well, but on July 9 the Ninth Army was stopped before a heavily fortified ridgeline and stayed there four days. On July 12, the Russians, confident that they had taken the measure of the Ninth Army's offensive, launched a strong attack of their own against the front north of Orel behind the Ninth Army. The Fourth Panzer Army was then just beginning to gather momentum.

On the next day, July 13, Hitler called the army group commanders to his headquarters and informed them that he had decided to halt Citadel. The situation north of Orel was precarious, and he was concerned about a Soviet threat to the Donets Basin; but his greatest source of worry was Sicily, where American and British troops had landed on July 10. The Italians, he said, were not fighting, and it was necessary to create new armies to defend Italy and the Balkans. Troops would have to be removed from the eastern front. Partly to gain troops for Italy, and partly because the offensive opened by the West Front, under Gen. (later Marshal) Vasili D. Sokolovski, and the Bryansk Front, under General Popov, had already gone too far, Hitler was forced to yield his own salient around Orel, ending the German threat to Kursk.

GERMAN WITHDRAWALS: 1943-1944

Soviet Summer and Fall Offensives: August-November 1943.—As the Russian campaign entered its third year, the world watched expectantly for the answers to two questions. Could the Germans recover from the effects of the winter battles for a second time and make another bid for victory? If not, could the Russians take the initiative without their old ally, "General Winter"? Citadel answered the first question, and the Soviet Army's subsequent performance erased the last lingering doubts inherent in the second.

After two years of war the Soviet Army was

Map 23. OPERATIONS ON THE EASTERN FRONT (Nov. 19, 1942–Dec. 15, 1944). The solid line on the map shows the front line on Nov. 19, 1942, the day the Russians counterattacked at Stalingrad. After the disaster the Germans withdrew rapidly in the south under heavy pressure. A successful German counterattack at Kharkov in March 1943 stemmed the Soviet advance. By July 4, Joseph Stalin's troops had overrun the area shown. A German attack the next day against the Kursk salient failed, and the Russians resumed the offensive. In a series of alternating attacks, which were costly to Adolf Hitler's strategic reserves, the advance overran the strong Dnieper River line by November 30. With scarcely a pause the offensive continued, now in the north as well as the south. By June 22, 1944, Leningrad and the Crimea had been freed, and Soviet troops were across the Rumanian border. Hitler's penchant for holding untenable positions made the German losses needlessly heavy. In the second half of 1944 the Russians struck several great blows concurrently with the Allied offensives in France and Italy. An attack through Minsk drove 250 miles in three weeks and destroyed two German armies. A blow in the north cleared Estonia, Lithuania, and most of Latvia; one in the south carried to the gates of Budapest, forcing Rumania and Bulgaria out of the war.

about to prove that it had completed its apprenticeship. It had developed tactics suited to large-scale offensive operations and had adapted them to its own limitations, which consisted primarily of a lack of initiative in the ranks and a frequent inability on the part of commanders and staffs below army levels to execute tactical maneuvers requiring precision or sensitivity to changing situations. The German blitzkrieg technique had delivered the decisive stroke with precision, speed, and economy of effort. The Russians, on the other hand, favored a broader lateral scope and more conservative execution. They adopted the breakthrough and penetration as basic tactical maneuvers, but they preferred to achieve the decisive effect by a series of relatively shallow

strokes along the breadth of the front rather than by one or several deep thrusts. Although the Russians claimed that Stalingrad had supplanted Cannae as the classic encirclement battle, they did not employ the double envelopment as frequently as the Germans had. More often they were content with a single thrust or with parallel thrusts, the objective being to force their opponent back on a broad front rather than to achieve a deep penetration along a single line of advance.

On the morning of Aug. 3, 1943, in the sector from which the Fourth Panzer Army had launched the southern arm of the attack toward Kursk, the massed artillery of the Soviet Sixth Guards Army laid down a barrage of several hours' duration on the German 167th Infantry

Division. When the artillery lifted its fire, 200 tanks roared into the German line, followed by waves of close-packed infantry. Before nightfall the German division was reduced to a few dazed survivors. Pouring through the gap, the Russians reached and took Belgorod on August 5. In another three days they had opened a 35-mile-wide gap on the right flank of the Fourth Panzer Army, giving them a clear road to the Dnieper River 100 miles to the southwest. On the same day, Manstein, the commanding general of Army Group South, informed Hitler that he lacked enough divisions to close the northern flank or to hold the long line on the Donets below Kharkov. He would either have to yield the Donets Basin or receive 20 divisions from somewhere else.

As he had on other occasions when confronted with unpleasant choices, Hitler avoided the decision by moving in an altogether different direction. He suddenly revived the idea of an East Wall, which he had rejected earlier. On August 12, he ordered construction started on a fortified line that was to begin in the south at Melitopol, run due north to the Dnieper River near Zaporozhe, follow the Dnieper to Kiev and the Desna to Chernigov, thence take a line almost due north to the southern tip of Lake Pskov, and, running along the west shores of Lakes Peipus and Pskov, anchor on the Gulf of Finland at Naiva. While it appeared that in ordering the East Wall Hitler had accepted a general retreat on the eastern front as inevitable, subsequent decisions revealed that he actually intended to establish a barrier behind which the armies could not retreat and, since no work of any kind had as yet been done on the so-called East Wall, give himself an excuse for holding out farther east.

In the last two weeks of August, the Soviet High Command expanded the offensive to the south and north. Kharkov fell on August 23. To the southeast the Russians broke through on the Donets south of Izyum and on the Mius River line east of Snigirevka. In the last week of the month they penetrated the Army Group Center front in three places. On August 31, Hitler gave the Sixth Army permission to retire from the Mius to the Kalmius River "if necessary." Three days later, he took a second positive step, ordering Army Group A to begin evacuating the useless beachhead which it still held on the Taman Peninsula.

The Sixth Army could not halt on the Kalmius. During the morning of September 6, a motorized mechanized corps and 9 Soviet rifle divisions broke through on the boundary between the Sixth and First Panzer armies. The next day a tank corps slipped through the gap, and, leaving the infantry behind, the two armored corps moved westward. By September 8, they were approaching Pavlograd, 30 miles east of the Dnieper and 100 miles behind the Sixth Army front. On that day, Hitler allowed the Sixth and First Panzer armies to start withdrawing to the line on which he had intended to build the East Wall, from Melitopol to the Dnieper north of Zaporozhe.

By September 14, the northern flank of Army Group South was disintegrating. The Fourth Panzer Army was split into three parts, and the Russians had a clear road open to Kiev. To the north, Army Group Center fared no better. The Second Army's front on the Desna, which was to have been part of the East Wall, was riddled with Soviet bridgeheads, and on September 14 the Russians began an offensive directed at Smolensk.

The next day, Hitler gave the two army groups permission to retreat to the line of the Dnieper, Sozh, and Pronya rivers. In most places the retreat was already under way, and in the last week of the month it developed into a race with the Russians for possession of the river lines. At the end of the month, as the last German troops crossed the rivers, the Russians had five bridgeheads on the Dnieper between the confluence of the Pripyat River and Dnepropetrovsk.

In two and one-half months, Army Groups South and Center had been forced back for an average of 150 miles on a front 650 miles long. The Germans had lost the most valuable territory they had taken in the Soviet Union. In an effort at least to deny the Russians the fruits of those economically rich areas, Hitler had instituted a scorched-earth policy, but in the end even that satisfaction was denied him. Nearly all of the factories, power plants, mines, and railroads could be destroyed, but the Germans lacked the personnel to transport or destroy more than a fraction of the agricultural and economic goods.

The Dnieper affords the strongest natural defense line in western European Russia, especially when the battle is moving from east to west. Fortified and adequately manned, the Dnieper line could have constituted an ideal defensive position, but Army Group South was so badly battered that the river provided at most a degree of natural protection and a tenuous handhold. Of the East Wall nothing was in existence; much of the proposed line had not even been surveyed.

On reaching the Dnieper, the Soviet Army had attained the original objectives of its summer offensive. Ordinarily the shortening of the German front, the defensive advantages of the river, the lengthening Russian lines of communications, and the attrition of the Russian forces could have been expected to bring the two sides into temporary balance. But Hitler had sacrificed too much of his strength east of the river. In contrast, the Russians' numerical superiority had enabled them to rest and refit their units in shifts, and they reached the Dnieper with their offensive capability largely intact. Before the last German troops crossed the river, the battle for the Dnieper line had begun.

In the first week of October, the whole eastern front was quiet as the Russians regrouped and brought up new forces. To underscore the victories achieved so far, they began renaming the front commands. Opposite Army Group South and the Sixth Army, which had passed to Army Group A, the Voronezh, Steppes, Southwest, and South fronts became the First, Second, Third, and Fourth Ukrainian fronts.

On October 9, the Fourth Ukrainian Front launched 45 rifle divisions, five tank and motorized mechanized corps, and two cavalry corps against the Sixth Army's 13 divisions in the line between Melitopol and the Dnieper. Within three weeks it drove the Sixth Army back across the flat, dusty Nogai Steppe to the lower Dnieper. Hitler refused last-minute requests to evacuate the Seventeenth Army from the Crimea, claiming that the Russians would thereby gain airfields from which to bomb the Rumanian oilfields. When the Sixth Army retreated beyond Perekop Isthmus, the Seventeenth Army was cut off, and in the first week of November Soviet troops gained beachheads on the Sivash Sea near the base of the isthmus and on the Kerch Peninsula.

While the Fourth Ukrainian Front was engaged below the Dnieper bend, the Second and

Third Ukrainian fronts operating against the First Panzer and Eighth armies carved a bridgehead 200 miles wide and 60 miles deep on the river between Cherkassy and Zaporozhze. On the south the Third Ukrainian Front threatened important iron and manganese mining areas near Krivoi Rog and Nikopol, which Hitler was determined to hold at any cost. The Russians had taken a large bridgehead at the confluence of the Pripyat and the Dnieper in September. South of it, on November 3, the First Ukrainian Front broke out of two smaller bridgeheads, and three days later it took Kiev. During the rest of the month it drove the Fourth Panzer Army back west and south of the city, threatening to demolish the entire left flank of Army Group South. To the north the Belorussian Front forced the right half of Army Group Center back from the Sozh River. Around Nevel, on the boundary between Army Groups Center and North, the First and Second Baltic fronts made a deep salient in the German front.

December brought some relief to the German armies, which for a few weeks regained their balance and even managed to counterattack west of Kiev. By this time the best solution for the German predicament would have been to withdraw Army Group South and the Sixth Army to the next major river, the Bug (Southern Bug), but Hitler would not consider it. He talked vaguely of retaking Kiev and of reopening the Crimean front. Actually, German prospects were worse than they had been in the two preceding winters. Opposing 3,000,000 German troops the Soviet Army had 5,700,000 men and an overwhelming superiority in tanks and artillery. In the summer and fall offensives the Russians had repeatedly laid down artillery barrages heavier than any since the great battles of World War I. Moreover, the German Army faced two new dangers: its manpower reserves were rapidly being exhausted, and an Anglo-American invasion in the west within the next half year was nearly certain. In November, Hitler notified the eastern front that it would have to manage on its own resources until the invasion had been defeated. The danger in the west, he said, was greater than that in Russia, and he could no longer take the responsibility for allowing the western front to be weakened for the benefit of other theaters of war. He suggested that possibly the eastern front might trade space for time, but events soon were to prove that he was constitutionally incapable of adopting this course.

Offensives on the Outer Flanks.—In the winter of 1943–1944 the weather, as always in Russia, became the third force in the fighting, but with a difference. The hard freeze which usually set in by mid-December and lasted into March did not arrive at all that winter in the south, and in the north it was frequently broken by thaws. Rain, sleet, slush, and mud tested the endurance of men and machines. Again the Russians had the advantage. They had sufficient reserves to give their troops occasional periods to rest and dry out. Their tanks, having wider tracks, performed better in mud than did the German armor. Their American-built lend-lease trucks ran through mud that hopelessly mired the two-wheel-drive German trucks. Both sides relied heavily on the light, high-riding one-horse *panje* wagon, the Russian peasant's answer to mud.

On Christmas Eve, the First Ukrainian Front drove two armies into the southern rim of the Fourth Panzer Army's front around Kiev, and the next day it developed a strong secondary thrust

to the west. Either of these thrusts could ultimately smash the entire southern flank of the eastern front. The thrust moving southward, if it reached the Black Sea coast, would envelop Army Groups South and A between the Dnieper and Dniester rivers. The thrust moving to the west, on reaching the Carpathian Mountains, could be employed to drive the two army groups back against the Black Sea and into the Balkans. Considering the first thrust the greater danger, Manstein ordered the Fourth Panzer Army to concentrate on stopping the Soviet armies going south, but even that task was temporarily beyond the army's strength. By mid-January, the First Tank Army, spearheading the First Ukrainian Front's southern thrust, had gained 65 miles and was approaching Uman.

On Jan. 10, 1944, the Third and Fourth Ukrainian fronts opened a two-pronged offensive against the Sixth Army. By the end of the month, mainly because Hitler rigidly insisted on holding the mines near Nikopol and Krivoi Rog, the Russians had nearly encircled the army's main force in the angle of the front east of Krivoi Rog. Not until February 19, after the army had lost nearly all of its vehicles and artillery, did Hitler give it permission to retreat to a line on the Ingulets and lower Dnieper rivers.

In the two years that had elapsed since the first Soviet winter offensive, Army Group North had by comparison with the rest of the eastern front been almost stationary. It had yielded some ground on the right, but it had kept its line firmly anchored on Lake Ilmen. Below the lake the old Russian towns of Staraya Russa and Kholm had lain directly on the front since the summer of 1941. Even the breakthrough at Nevel in October 1943 was more significant as a portent of a possible Soviet drive to outflank the army group in the south than for the immediate loss of ground it entailed. South of Lake Ladoga the army group had fought three battles to keep Leningrad under siege and had held the Russians to a token gain of a few miles along the lake shore. From the Volkhov River to the Gulf of Finland the front resembled a World War I battlefield. It was a complicated lacework of trenches and shell holes, the result of two and one-half years' fighting in which gains and losses on both sides could be measured in yards. By January 1944, however, the stable front no longer reflected the actual condition of the army group, which had lost its best divisions through transfers.

On January 15, the Leningrad Front launched two strong attacks, one south of the city and the other from the pocket around Oranienbaum (now Lomonosov) to the east. On the same day, the Volkhov Front struck at Novgorod north of Lake Ilmen. By the end of the fifth day of the battle, the German front was disintegrating in all three places, and on January 19 the Soviet troops completed the liberation of Leningrad. Thereafter the entire left flank of Army Group North cracked. Hitler, concerned about the effect that a more extensive retreat would have on Finland, which was already negotiating tentatively with the Soviet Union, at first ordered the army group to build a new front line on the Luga River. This attempt had no chance of success, and on February 13 he was forced to order the army group back into the Panther Line, the Narva River–Lake Peipus–Lake Pskov section of the ill-fated East Wall. The Panther Line was the only major part of the wall on which substantial work had been

lone, and when the army group reached it on March 1, it held.

During January and February, Army Group South fought in knee-deep mud, sleet storms, and blizzards to keep its front together. The First and Fourth Panzer armies managed to halt the Soviet southward thrust northeast of Uman, but by that time the First and Second Ukrainian fronts, with Zhukov commanding as at Stalingrad, had encircled two German corps northwest of Cherkassy. Army Group South concentrated almost its entire tank strength to rescue the corps, and on the night of February 17 approximately 30,000 men, about half the number originally in the pocket, broke out. In the meantime, the left flank of Army Group South had been driven behind the 1939 Polish border nearly to Kovel (now Kovel), Luck (now Lutsk), and Dubno. At the end of February, Army Groups South and A held a weak but (for the first time since Christmas) almost continuous line about halfway between the Dniester and the Bug.

Western Ukraine and the Crimea: March-May 1944.—After mid-February, it appeared to the German High Command that the army groups on the eastern front had seen another winter through. Army Group North was retiring to a fortified line. Army Groups South and A were less well provided for, but after the breakout from the pocket near Cherkassy the Russians were not on the march anywhere, and anyone who wanted to overlook the fact that the Soviet armies had continued to move through an abnormally warm, wet winter could assume that in a matter of days—in a few weeks at most, when spring set in—the front would sink into the mud for a month or so.

Field Marshal von Manstein was not so hopeful. He believed that the Russians would attempt at least to advance another 35 miles and cut the Lvov (now Lvov)-Odessa railroad behind Army Group South's left flank. The signs were plentiful that they could resume the offensive if they wished. During the fighting in January and February, the four Ukrainian fronts had at no time brought all of their strength to bear, and their reserves, instead of declining, had grown enormously. By mid-February, the Soviet High Command had shifted five of its six tank armies to the area opposite Army Group South. Three of them remained in reserve. At the end of the month the sixth tank army also appeared. The American-built trucks, the wide-tracked Soviet tanks, and the *panje* wagons had proved their ability to keep an offensive rolling through mud.

On March 4, the First, Second, and Third Ukrainian fronts attacked. The First Ukrainian Front, the strongest of the three, struck due south from the vicinity of Shepetovka into a gap between the First and Fourth Panzer armies' flanks. The Second Ukrainian Front hit the Eighth Army's center east of Uman, and the Third Ukrainian Front drove through the center of the Sixth Army below Krivoi Rog. The Soviet offensive advanced rapidly through the mud. Except on the left against the First Ukrainian Front, the Germans usually lacked sufficient troops even to place temporary roadblocks in the Russians' way. In quick succession the Soviet spearheads crossed three potential German defense lines, the Bug, Dniester, and Prut rivers. In the last week of March, the whole First Panzer Army was encircled at Kamenets-Podolski and had to break out to the west. After gaining 165 miles on the three main

thrust lines, the Soviet offensive halted in mid-April, leaving the Germans with a front which at its center was backed up against the Carpathians, and which they managed to hold only by utilizing, for the first time since Stalingrad, one Hungarian and two Rumanian armies.

At the height of the offensive, on March 30, Hitler had called the commanding generals of Army Groups South and A, Manstein and Kleist, to his headquarters and had dismissed them. On the eastern front, he had explained, the day of the master tacticians was past. What he needed were ruthless generals who would drive their troops to the utmost and extract the last ounce of capability for resistance. The two new-style generals whom he appointed were Field Marshal Walter Model to command Army Group South and Col. Gen. (later Field Marshal) Ferdinand Schörner to command Army Group A. A few days later, in a typical empty gesture, he redesignated Army Groups South and A as Army Groups North Ukraine and South Ukraine.

On April 8, almost as an afterthought, the Fourth Ukrainian Front launched an attack on the Crimea. The Seventeenth Army's front on Perekop Isthmus disintegrated in two days, and by April 16 the army was forced back to a small beachhead around Sevastopol. Until early May, Hitler had insisted on holding Sevastopol—to keep Turkey neutral, he said. By then the Russians had a clear field of observation across the whole beachhead to the tip of Cape Khersonesski. During four nights, German ships from Constanta, Rumania, attempted to evacuate the army, but only about half of the 65,000 men on the peninsula escaped. Meanwhile, on May 9, Sevastopol was reoccupied by the Russians.

SOVIET VICTORIES: 1944-1945

Collapse in the Center: June-August 1944.—In April and May 1944, it appeared, at least to Hitler and his closest advisers, that destiny might yet be made to bow to the führer's will. Everything depended on whether the invasion in the west, to which the United States and Great Britain had committed themselves at the Teheran Conference (Nov. 28-Dec. 1, 1943), could be defeated. A victory in the west would release the approximately 45 percent of its strength which Germany had retained there while awaiting the invasion.

Hitler's luck and his ability to win against heavy odds seemed not to have deserted him completely. Despite the disastrous winter, he had succeeded in maintaining his determination not to weaken the western defenses for the sake of the east. In March, he had been forced to send several panzer divisions to the east, but by the end of April he managed to form new divisions to replace them. Thereafter he was as nearly ready as he intended to be, and the Russians helped him indirectly by giving no sign that they intended to do anything to make their allies' landing easier. German industrial output was still rising. Synthetic oil production reached its peak in April, and the Luftwaffe had about 40 percent more planes than it had possessed a year earlier. The production of tanks and weapons was sufficient to equip new divisions for the west and to replace some of the losses in the east. All in all, it seemed that Germany could await the next roll of the dice with some confidence.

By mid-June, the dice had been rolled, and Germany had lost. Beginning in April and con-

tinuing through May and into June, the United States and British air forces staged bombing raids that eliminated 90 percent of the German synthetic oil production. On June 6, United States and British troops landed in Normandy, and in the next several days the strategy that Hitler had carefully nurtured since November 1943 collapsed. The powerful counterattack that he had envisioned did not materialize. Because he expected a second landing north of the Seine, he refused to take troops from the Fifteenth Army, which was closest to the Normandy beachhead, and decided instead to draw reinforcements from more remote areas. Consequently, the invaders were not driven from the beaches, and the German forces in Normandy were forced to the defensive.

In the east, Hitler and the Army General Staff expected the Russians to renew their pressure against the southern flank, attempting to smash Army Group North Ukraine against the Carpathians and drive Army Group South Ukraine into the Balkans. For the center they predicted a quiet summer. To meet the expected attack against Army Group North Ukraine, they transferred a panzer corps from Army Group Center and so deprived the latter of more than 80 percent of its tanks.

Army Group Center held the last major stretch of Soviet territory left in German hands: Belorussia eastward to the ancient gateway to Moscow between Vitebsk and Orsha 290 miles west of the Soviet capital. On June 22–23, the Russians attacked—not Army Group North Ukraine, as had been expected—but Army Group Center. Vasilevski was coordinating the First Baltic and Third Belorussian fronts at Vitebsk and Orsha, while Zhukov coordinated the Second and First Belorussian fronts opposite Mogilev and Bobruisk. In three days the Russians had made deep penetrations along the entire front. Hitler, who was determined not to yield any more ground in the Soviet Union, refused to allow segments of the front still standing to retreat. The Third Panzer Army on the north lost contact with Army Group North and began to drift with the Russian tide. In the center the flanks of the Fourth and Ninth armies were broken through. By the end of the month, the First Belorussian Front had trapped and was destroying two thirds of the Ninth Army around Bobruisk. Only the headquarters and one corps escaped. The commanding general of the Fourth Army had taken matters into his own hands and ordered his troops to retreat, but the army had to make its way through roadless forests and cross the Dnieper, Drut, and Berezina rivers. The Russians on its flanks were moving faster, and on July 3 they closed the army's last escape route at Minsk. In less than two weeks, Army Group Center had lost 25 of its 38 divisions.

On June 28, Hitler had combined the command of Army Groups Center and North Ukraine under Field Marshal Model. He intended by this step to facilitate the transfer of divisions from Army Group North Ukraine to Army Group Center, but by that time the former was itself threatened and could not spare many troops. To gain troops the generals favored withdrawing the northward-jutting front of Army Group North from the Narva-Lake Peipus line to a short line between Daugavpils (Dvinsk) and Riga, but Hitler would not agree. He was concerned about the effect on Finland and the danger to the navy's submarine training ground in the Baltic Sea. All Model could do was to commit what reinforce-

ments arrived, maneuver to gain the semblance of a coherent front, and wait for the Russians to lose their momentum.

In July, the Soviet offensive spread to the flanks. On the north the First Baltic Front drove into the gap between Army Groups Center and North toward East Prussia and the Baltic. On its right the Second and Third Baltic fronts forced Army Group North back to the Pskov-Daugavpils line. On July 29, a spearhead of the First Baltic Front reached the Baltic west of Riga and cut off Army Group North.

On the southern flank of Army Group Center the First Belorussian Front, powerfully assisted by an offensive which the First Ukrainian Front began against Army Group North Ukraine on July 13, developed a two-pronged thrust toward Brest (Brest-Litovsk). Late in the month, the First Belorussian Front carried its advance past Brest to Lublin and then turned northwestward toward Warsaw (Warszawa). The Russian point reached nearly to the Warsaw suburb of Praga on July 31. On the next day an uprising led by Tadeusz Komorowski (General Bor) broke out in Warsaw. East of the city, however, the Germans encircled and destroyed the leading Soviet tank corps, and thereafter the Russians left the Warsaw insurgents to their fate. While the First Belorussian Front devoted its attention to consolidating two bridgeheads south of Warsaw, the SS moved into the city, where after two months of savage fighting General Bor surrendered on October 2.

In August, the Soviet offensive subsided. Advancing as much as 350 miles in a little more than a month, the fronts had outrun their supplies. Army Groups Center and North Ukraine had been forced back to a line on the Vistula (Visla) and Narew (Narev) rivers and the East Prussian border, and the Russians held valuable bridgeheads across both rivers.

Beginning on August 16, Army Group Center launched a small counteroffensive that opened a narrow land corridor south of Riga to Army Group North. The respite was brief. On September 14, the three Baltic fronts began attacking toward Riga. When the Leningrad Front joined the offensive and on September 17 broke through at Tartu, Army Group North had to retreat to avoid being cut to pieces. At the end of the month the army group barely succeeded in escaping through the corridor south of Riga. On October 1, the First Baltic Front attacked due westward to the Baltic coast, which it reached near Memel (Klaipėda) on October 10. With that, Army Group North was cut off once more and had to withdraw into Courland (Kurland) west of Riga. It might still have broken out to the south, but Hitler insisted that it stay in Courland. He intended, he said, to open an offensive from there soon.

Operations on the Southern Flank.—Although its front had been quiet, Army Group South Ukraine was badly weakened by mid-August 1944. It had lost 5 of its 6 armored divisions and 4 infantry divisions through transfers. The Rumanians, both troops and civilians, were thinking increasingly of peace. On the morning of August 20, the Russians attacked. The Second Ukrainian Front struck southward past Iasi, and the Third Ukrainian Front pushed westward from two bridgeheads on the Dniester near Tiraspol. On August 25, they trapped the inner flanks of the Sixth and Eighth armies in an encirclement near Kishinev. On the same day, Rumania, having announced its acceptance of Allied armistice terms

On August 23 (the armistice was signed on September 12), declared war on Germany. The front dissolved into chaos. Some elements of the Eighth Army escaped into the Carpathians, while survivors of the Sixth Army fought their way southward between the mountains and the lower Danube River. On August 30, the Second Ukrainian Front captured the Ploesti oilfields, and the next day it entered Bucharest (Bucuresti). The Third Ukrainian Front occupied the Dobruja, and on September 8 crossed into Bulgaria, which requested an armistice (granted September 9) and declared war on Germany.

The thrusts into Rumania and Bulgaria automatically brought about the collapse of the German southeastern theater: the 300,000 Wehrmacht troops, organized into Army Groups E and F, who were defending the Adriatic and Aegean coasts and fighting partisans in Yugoslavia and Greece. Army Group E in Greece and Albania, after airlifting its troops from Crete and the other Greek islands, was forced to undertake a long and precarious march through the mountains of western Yugoslavia, which it did not complete until mid-November. Meanwhile, in September, the headquarters of the Eighth Army and the Sixth Army, using what troops they still retained, established fronts in the eastern Carpathians and the Transylvanian Alps. Farther to the west the Hungarian Second and Third armies formed a line on the border. In the second half of the month the Second and Third Ukrainian fronts regrouped and began turning northward for an offensive into Hungary and northeastern Yugoslavia.

The Third Ukrainian Front began operations on September 28 with an attack from Bulgaria toward Belgrade (Beograd). Three days later, the Second and Fourth Ukrainian fronts, coordinated by Marshal Timoshenko, began driving across the mountains in eastern Hungary. Belgrade fell on October 20. On the same day, the Second Ukrainian Front took Debrecen, and the Germans evacuated Transylvania to escape encirclement. By the end of the month the Second Ukrainian Front was across the Tisza (Tisa) River, and the Third Ukrainian Front had turned northward from Belgrade along the east bank of the Danube, which it began crossing near Apatin. In November, both fronts launched attacks toward Budapest against stiff German resistance. (Troops from Army Groups E and F had reinforced the Sixth and Eighth armies.) The first Soviet troops reached the outer Budapest defense ring on November 8, but Soviet progress was slow for the next six weeks. Finally a thrust by both fronts, begun on December 20, completed the encirclement of Budapest on December 27. Two days later, a Soviet-sponsored provisional Hungarian government declared war on Germany.

Operations on the Northern Flank.—Finland had gained its territorial objectives by November 1941, and after December of that year it had watched the war on the German front in the south with growing apprehension. The country was fortunate in that both Britain and the United States saw a certain amount of justice in its cause against the Soviet Union. At the Teheran Conference, President Franklin D. Roosevelt and Prime Minister Winston Churchill had persuaded Stalin to offer the Finns a negotiated peace on terms that would leave the country independent, but after a first appraisal of the Soviet terms the Finnish government, in March 1944, had found

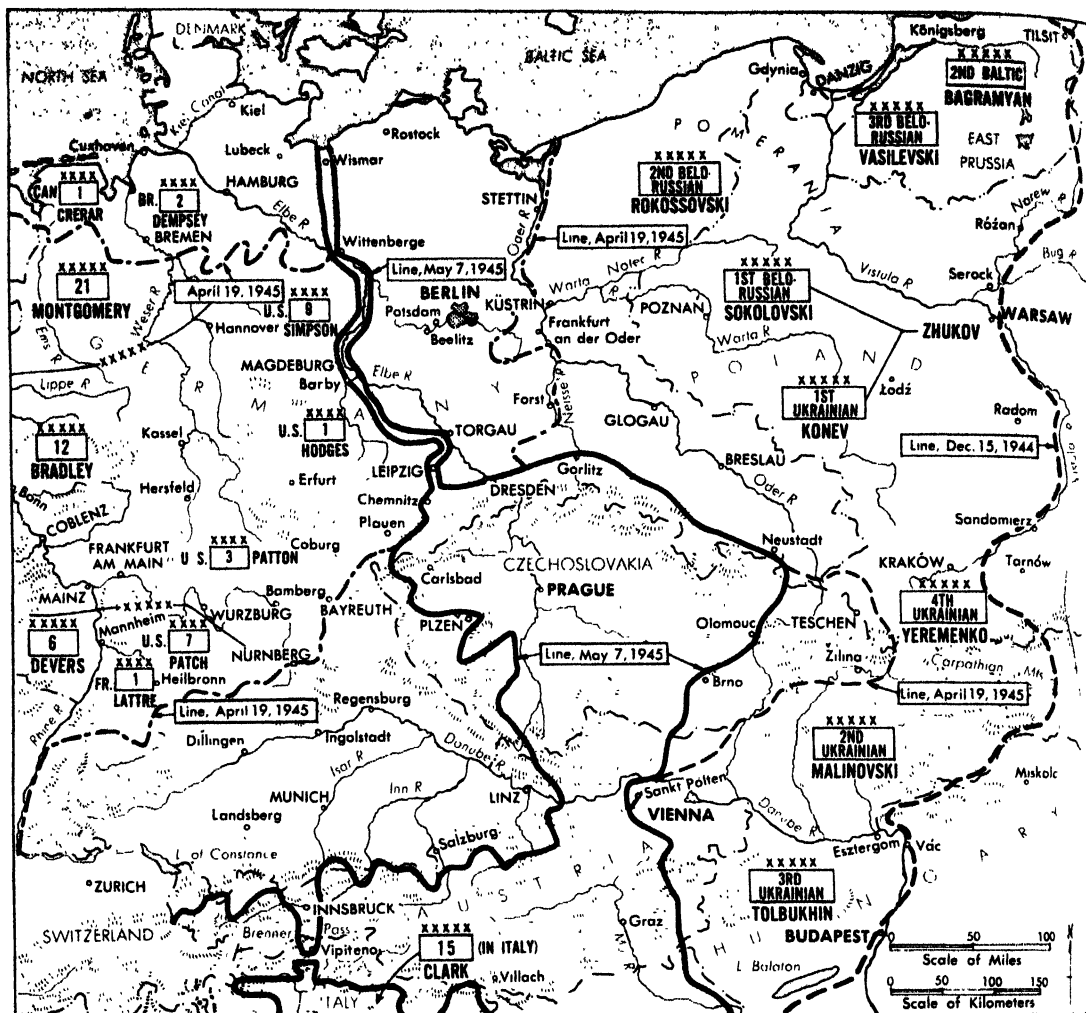

them too onerous and rejected them.

On June 9, the Russians opened an offensive on the Karelian Isthmus, and in a month they had driven the Finnish Army back nearly to the 1940 border. The Finns were fortunate again in that a somewhat less than masterful Soviet performance, their own quick recovery after initial defeats, and German aid enabled them to keep the Russians from breaking into the heart of the country. On September 2, Finland appealed for an armistice, and on September 19 it signed the Soviet peace terms, which were oppressive but did not include a military occupation.

When the armistice went into effect, the German Twentieth Mountain Army still occupied Finnish Lapland north to the Arctic coast. After failing in 1941 to take Murmansk or to cut the Murmansk Railroad, it had settled down to positional warfare along the Soviet-Finnish border. Finland's removal from the war threatened to leave the army's southern flank dangling in a void. At first, Hitler wanted to swing the flank westward and hold northern Finland for the sake of the nickel mines near Petsamo, but later he decided to withdraw the entire army into the northern tip of Norway and then southward along the German-built coastal road. On September 6, the 200,000-man Twentieth Mountain Army began a four month's march across 500 miles of Arctic wilderness. In accordance with the Soviet armistice terms, the Finns attempted to disarm the Germans, but after several clashes in the south they did not interfere with the retreat (Finland formally declared war on Germany on March 3, 1945). The Russians, after failing to destroy the German corps stationed at Petsamo, halted their pursuit west of Kirkenes, Norway.

Advance into the Reich: January–April, 1945.—At the turn of the year 1944–1945 the eastern front, bisected by the mountains of eastern Czechoslovakia, stood in the north approximately on the line reached in August 1944. In the south it followed the Czechoslovakian border to the west of Budapest and then veered southward along the line of Lake Balaton and the Drava and Danube rivers. In the north the Russians had bridgeheads across the Narew and Vistula rivers at Rózan, Serock, and Sandomierz. In the south they had encircled Budapest and had nearly reached the last German-held oilfield at Nagykanizsa. The routes to Berlin and the Silesian industrial region lay open across the Polish plain, but Hitler hoped that he could recover some of his prestige by a victory in the south. After Christmas he had transferred the 4th SS Panzer Corps from the Warsaw front to the front near Budapest.

Between January 12 and January 14, the First, Second, and Third Belorussian fronts and the First Ukrainian Front attacked. Exploiting the bridgeheads, each front achieved a complete breakthrough on the first or second day. The Second and Third Belorussian fronts went northwestward and westward against East Prussia from the line north of Warsaw. By January 26, they had driven a spearhead through to the Baltic coast east of Danzig (Gdańsk), and they then began cutting up the two German armies to the northeast. The First Belorussian and First Ukrainian fronts moved westward from the front between Warsaw and the Sandomierz bridgehead toward the Oder River. After the first four days the breakthrough was so thoroughly accomplished that the Soviet armies could move in columns along the roads at speeds averaging between 20 and 25 miles a day.

Map 24. FINAL SOVIET OFFENSIVES (Jan. 12–May 7, 1945). By mid-January 1945, the Russians had assembled reserves and supplies and were ready to resume the offensive. Springing from the line marked Dec. 15, 1944, the armies in the north pushed ahead rapidly. By early February 1945, they had reached the Oder River, but there they were held up for several weeks. In mid-April, after regrouping, they broke through the German defenses and struck for Berlin. In the south the offensive moved generally up the Danube Valley, captured Budapest and Vienna, and, in conjunction with Marshal Tito's Yugoslav partisans, cleared the Germans from most of the Balkans. The map shows the positions of the Allied forces in the west and in the east on April 19 and May 7, the date of the German surrender. The United States First and Ninth armies had reached the Elbe by April 19, but they halted at that river line in accordance with prior Allied agreements.

The First Belorussian Front bypassed Poznań on January 22, and by February 3 had drawn up to the Oder on a broad front 36 miles east of Berlin. A week earlier, the First Ukrainian Front had reached the middle Oder and established several bridgeheads. On February 8, it began attacking across the Oder north of Breslau (now Wrocław), and by early March had cleared Silesia and had then halted on the Neisse (Lusatian Neisse) River line.

On the northern flank of the First Belorussian Front the newly created German Army Group Vistula still held a long front between the lower Oder and lower Vistula in early February. In the middle of the month the Germans attacked from that front into the rear of the Russians on the Oder opposite Berlin. The attack failed, and on February 24 the First Belorussian Front turned to the north. By March 10, it had thrown one German army back against the Baltic coast near Danzig,

had driven through Pomerania (Pomorz) to the sea, and had cleared the right bank of the Oder to its mouth.

On the front in Hungary the Germans staged three attempts during January to relieve Budapest. The third, which began on January 18, penetrated deeply into the Soviet front but did not reach the city. On January 27, the Third Ukrainian Front counterattacked, and Budapest fell on February 13. In mid-February, Hitler transferred the Sixth Panzer Army from the Ardennes to Hungary, where he illogically insisted on attempting to regain the Danube line. The offensive began on March 6 and continued for 10 days without significant gains. On March 16, the Second and Third Ukrainian fronts struck back and in a little more than a week broke through on both sides of Lake Balaton. On March 30, the Russians crossed the border into Austria, and on April 13 they took Vienna.

Last Soviet Offensive.—By April 1, 1945, Germany had been defeated. Silesia was gone, and the Ruhr was encircled. The output of tanks, artillery, and ammunition in the first quarter of 1945 was only about half the monthly average for 1944. From January through March, the Luftwaffe received between a twelfth and a twentieth of its requirements in aviation gasoline. The eastern and western fronts stood back to back with no room in which to maneuver. The war continued because Hitler was still in command, and he hoped for another "miracle of the house of Brandenburg," a collapse of the enemy coalition like that in the Seven Years' War which had rescued Frederick the Great from similarly desperate straits.

On the Oder-Neisse line the Russians in April regrouped the Second Belorussian Front in the north under Marshal Konstantin K. Rokossovski, the First Belorussian Front in the center opposite Berlin under Marshal Zhukov, and the First Ukrainian Front in the south under Marshal Konev. The First Belorussian and First Ukrainian fronts opened the offensive on April 16. Konev's armies achieved a complete breakthrough on the first day. The First Belorussian Front, heading straight toward Berlin from a bridgehead at Küstrin (now Kostrzyn) on the Oder River, was not so fortunate. It required two days to break out of the bridgehead and then was stopped again on April 21 at the outskirts of Berlin. In the meantime, the First Ukrainian Front had turned two tank armies to the northwest. By nightfall on April 24 they and elements of the First Belorussian Front coming from the north had closed a ring around the city. The next day, the Soviet Fifth Guards Army made contact with the United States First Army at Torgau on the Elbe River south of Berlin, and Germany was split into two parts.

Hitler had decided to remain in Berlin to the end. From his elaborate air-raid shelter he attempted to maneuver armies as he had in the old days. His first order, following the standard pattern which had failed so often in the past three years, was to hold the line and close the gaps. It was impossible to execute. On April 20, the Second Belorussian Front forced the Third Panzer army from the Oder. By that time the Ninth army was trapped between the flanks of the First Ukrainian and First Belorussian fronts. On April 4, Hitler ordered the Ninth Army to strike toward Berlin from the south and the Twelfth Army, facing American forces on the Elbe, to turn around and drive into the city from the west. The Twelfth Army managed to make the turn and reached Beelitz, 18 miles southwest of Berlin; here it was halted. On April 30, Hitler committed suicide, and two days later resistance ended in Berlin.

In the last week of the war the German armies on the eastern front all had one objective: to escape capture by the Russians. North and west of Berlin the Third Panzer, Twenty-first, and Twelfth armies succeeded in making agreements with United States Army commands which allowed them to pass through American lines. Army Group Center's Fourth Panzer, Seventeenth, and First Panzer armies were farther east on the upper Elbe River and in Czechoslovakia. After the unconditional surrender in Reims on May 7 (a second surrender ceremony was held in Berlin on May 9), they attempted a mass escape to the west but were stopped forward of the American-Soviet demarcation line, and nearly all of them, or about 1,000,000 men, passed into Soviet captivity. Some

troops of Army Groups South, E, and Courland escaped in the last days, but most fell prisoner to the Russians. All told, the Russians took about 2,000,000 prisoners in the days immediately preceding and following the surrender.

In sheer material and human destructiveness the Russian campaign had no equal in World War II. The total German dead, either as battle casualties or as prisoners of war, probably numbered about 3,500,000. Soviet losses were at least twice as great and may have gone much higher without even beginning to include deaths among the civilian population resulting from German or Soviet action. That Germany lost the campaign can be attributed primarily to its being forced into a conflict of mass against mass which far outran its industrial and human resources. Unable from the first to compete with the Russians in expending human life, the Germans were eventually crushed by the weight of Soviet arms. After 1941, Soviet war matériel production quickly overtook and surpassed that of Germany. Additionally, the USSR received lend-lease aid, mostly from the United States, valued at over \$11 billion. Among the more significant items were 409,526 trucks, 12,161 tanks and self-propelled guns, 14,000 airplanes, and 325,784 tons of explosives. Furthermore, the Soviet Union was able to commit more than 90 percent of its military strength against Germany, while the Germans were forced to retain a large part of theirs (35 to 45 percent in the years 1943 and 1944) in other theaters.

7. Balkan Campaigns

During nearly the entire first year of World War II, Hitler's primary concern with southeastern Europe was to avoid trouble in the area. By the late summer of 1940, however, his attitude had begun to change. The Soviet Union had annexed Bessarabia and northern Bucovina in June, and it clearly intended to reach farther south and west at the first good opportunity. Hitler, on the other hand, had started to think in terms of a conflict with the USSR. In such an eventuality he would need security on his deep southern flank, and above all he would need Rumanian oil. He would still have preferred to establish German hegemony in the Balkans without fighting, and he would probably have succeeded in doing so had Benito Mussolini not made his bungling attempt to invade Greece from Italian-occupied Albania on October 28.

The Italian attack was planned as a police action in the style of the German triumphal march into Czechoslovakia. Its general purpose was to show the world that Mussolini was not always dependent on Hitler: specifically, it was intended to match the action of the Germans, who three weeks earlier had unilaterally stationed troops in Rumania, then under a joint German-Italian guarantee. Hitler, who had been irritated by his Axis

Map 25. ITALO-GREEK WAR (Oct. 28, 1940–March 1, 1941). To emulate his mentor, Adolf Hitler, Benito Mussolini planned a triumphal entry into Greece, such as the führer had made into Czechoslovakia. His troops advanced across the Albanian border on Oct. 28, 1940, in four columns (heavy black arrows). But the Greeks were not passive; their resistance stiffened, and by November 8 the Italian advance had been halted at the points shown. Then, with the aid of British air contingents that had arrived in Greece on November 3, the Greeks counter-attacked. Relentlessly they pushed forward; by mid-December, the Italians had been driven 50 miles behind the border. Mussolini sent heavy reinforcements to Albania and counterattacked several times, but to no avail. By March 1, the line had been stabilized as shown. Hitler's imminent invasion of Yugoslavia and northern Greece was to relieve the Italian dictator of further embarrassment.

partner's unexpected move, became furious when the collapse of the Italian offensive close to the Albanian-Greek border opened the way for the development he wanted least of all, British intervention in Greece. The British occupied Crete and Lemnos (Limnos) on October 31, and in the next few days they established air units in southern Greece within bombing range of the Rumanian Ploesti oilfields. On November 4, Hitler ordered the German Army High Command to begin preparing for an attack on Greece.

Faced with a delay of four or five months until good campaigning weather returned, the Germans sought to open the approaches to the northern Greek border by political means. In November, Hungary and Rumania adhered to the Tripartite Pact of the Axis (concluded by Germany, Italy, and Japan in September). The Rumanian dictator, Gen. (later Marshal) Ion Antonescu, welcomed this insurance against the Soviet Union. Bulgaria, which was to provide the actual

staging area for the operation against Greece, hesitated to commit itself in view of possible unfavorable Soviet and Turkish reactions. Hitler, knowing that Bulgaria as one of the defeated nations in World War I would find it difficult to refuse an opportunity to obtain revenge, was willing to move slowly. German army engineers began bridging the Danube River on Feb. 28, 1941 and on March 1, just before German troops crossed the Rumanian border into the country, Bulgarians signed the Tripartite Pact.

In the case of Yugoslavia, Hitler was prepared to accept limited adherence to the Axis, for all he required was the use of the Belgrade (Beograd) Niš-Salonika railroad. (Rail connections through Bulgaria were poor.) The Yugoslav government resisted his overtures, but in mid-March, after having refused several earlier invitations, it suddenly changed its policy and offered to sign the Tripartite Pact. The ceremony was held in Vienna on March 25. A day and a half later, on the night of March 26–27, a military coup d'état forced Prince Regent Paul into exile. Young King Peter II was declared of age, and Gen. Dušan Simović formed a new government. While it did not denounce the recent adherence to the Tripartite Pact, it refused to ratify Yugoslavia's signature.

On March 27, Hitler declared that he was determined "to destroy Yugoslavia as a military power and a sovereign state," and he ordered the Wehrmacht staffs to complete military preparations at the greatest possible speed. Turning to their traditional protectors, the Russians, the Yugoslavs sent a delegation to Moscow on April 3. They failed to obtain a mutual assistance pact, however, and on April 5 were forced to accept instead a relatively meaningless treaty of friendship and nonaggression. The next day the German invasion began.

Campaign in Yugoslavia.—A rugged, mountainous terrain and wide-meshed, underdeveloped road and rail networks were Yugoslavia's strongest potential defensive assets. Although these assets were to be important during the years of guerrilla warfare, they did not serve to improve the country's very difficult strategic position in April 1941. To defend a land frontier of 1,700 miles the Yugoslav Army had a hypothetical maximum strength of 1,000,000. Even if it had been able to call up that many men, it could not have armed and equipped them. Since 1939 the army had been cut off from its principal supplier of weapons and ammunition, the Škoda works in Czechoslovakia. Nevertheless, the General Staff proposed to employ eight of its nine armies, which at full strength were approximately equivalent to German corps, in a linear defense of the entire frontier. In the first week of April, it rejected a Greek plan to sacrifice most of the country for the sake of securing a strong common front with the Greeks and the British in the south. Moreover, no matter what the staff intended, deep-seated differences between the Serbian and Croatian elements in the population threatened to divide both the army and the nation as soon as war broke out.

When Gen. (later Field Marshal) Sir John Greer Dill, the British chief of staff, visited Belgrade on April 1, he found the government confused and almost apathetic. It seemed above all to wish to avoid provoking the Germans in the forlorn hope that a conflict could still be avoided or at least postponed. In the end, the only cooperation arranged between the Yugoslav and Greek forces took the quixotic form of a projected

joint offensive against the Italians in Albania.

For the Germans the operation against Yugoslavia, in full swing 10 days after it was first ordered, was mainly an exercise in staff virtuosity. The most difficult task was to shift the German Second Army, composed of nine divisions under Col. Gen. (later Field Marshal) Maximilian von Weichs, to the northern Yugoslav border. The divisions had to be moved by rail and truck from France, Germany, and the Soviet border. The other major attack force, consisting of the five divisions of the 1st Panzer Group under Col. Gen. (later Field Marshal) Ewald von Kleist, was diverted from the assembly for the attack on Greece.

The plan was for the Second Army to break through the Yugoslav lines on a broad front north and northeast of Zagreb and to advance southward between the Drava and Sava rivers toward Belgrade. The 1st Panzer Group was to cross the border northwest of Sofia (Sofiya), Bulgaria, take Niš, and thrust northward up the Morava Valley to Belgrade. A third force, the 41st Panzer Corps, taking the short route across the Rumanian border from the area south of Timișoara, was to converge on Belgrade from the northeast.

In the early morning hours of April 6, German planes bombed Belgrade. They came in at rooftop level, and in an hour and a half killed more than 17,000 of the city's inhabitants and almost completely destroyed the Yugoslav High Command's communications with its forces in the field. The 1st Panzer Group crossed the border at daylight on April 8. While it encountered the Yugoslav Fifth Army, one of the few fully mobilized Yugoslav units, rough terrain and roadblocks proved to be the chief obstacles to its advance. After taking Niš on April 9, it broke away rapidly to the north toward Belgrade. In the meantime, another German force cut across southern Yugoslavia to divide the country from Greece. The Yugoslavs had opened their Albanian offensive on April 7, and for three days they made steady progress against the Italians.

The German Second Army launched local attacks on April 6, but because some of its major elements were still on the way, it did not attack in full strength until April 10. On that day, the Croat troops in the Yugoslav Fourth and Seventh armies, stationed on the northern frontier, mutinied, and by nightfall both armies had been dissolved. On the afternoon of April 10, Second Army troops entered Zagreb, where a newly created Croat government welcomed them as liberators. During the day, conceding by implication that he had lost control of the situation, General Simović called on all Yugoslav units to engage the enemy "wherever they met him and by any means" without waiting for orders from higher headquarters.

German forces converged on Belgrade from three directions on April 12. In the early evening an SS lieutenant from the 41st Panzer Corps took a patrol into the capital, hoisted the swastika flag over the German legation, and accepted the mayor's offer to surrender the city. On the morning of the following day, Easter Sunday, German armored spearheads entered Belgrade. The chief of the German Army General Staff noted in his diary that the campaign was over: all that remained was the mopping up. The Second Army had three columns moving westward and southward toward Sarajevo to block any attempt to establish a front in the mountains, but it encountered only masses of troops waiting to sur-

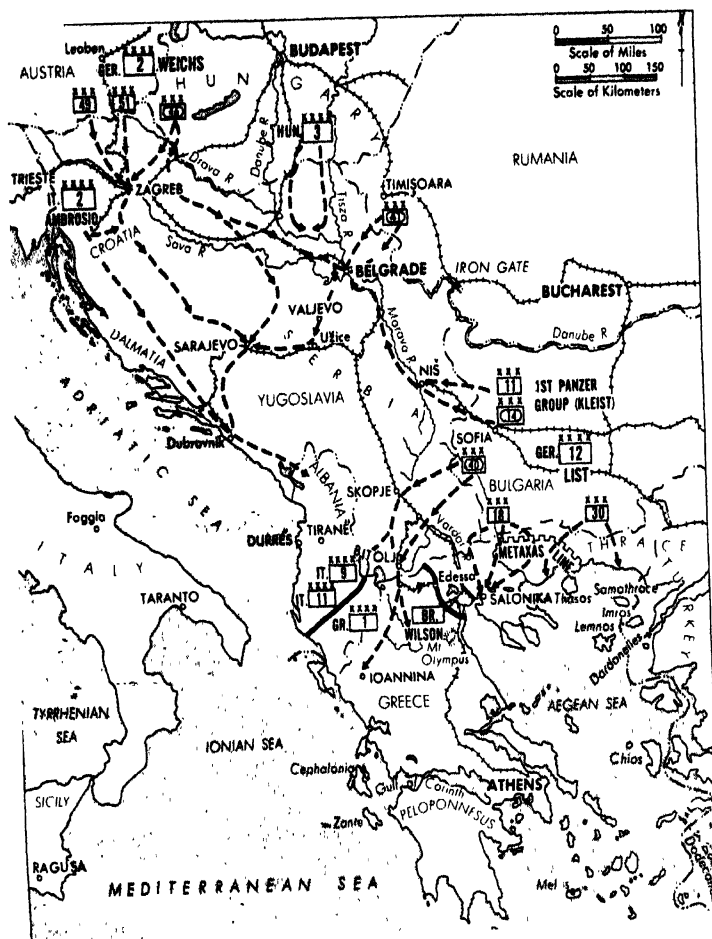

render. In some places fighting had broken out between Croat and Serb units.

On April 14, Gen. Danilo Katafotović took command of the Yugoslav forces and opened negotiations for an armistice, which was signed three days later. German casualties in the campaign totaled 558; those of the Yugoslavs ran much higher. The Germans took 344,000 prisoners. The Yugoslav Army had mobilized approximately 500,000 men, but many of them deserted before the fighting ended. Others, following the national tradition, slipped away to carry on guerrilla warfare. Chetnik (četnići) units had been organized before the invasion began, and later Partisan groups also were formed.

Campaign in Greece.—The Greek High Command was fully aware that Germany would not permit its ally, Italy, to be embroiled in an embarrassing little war indefinitely. In mid-February 1941, therefore, the Greeks seized their last chance and opened an offensive that was intended to drive the Italians from Albania before the Wehrmacht could intervene. The offensive made progress, but it was not sufficient. At the turn of the month, German troops marched into Bulgaria, and a British expeditionary force, which with earlier arrivals eventually numbered approximately 62,500 troops, began moving into Greece. Because of its fear of provoking the Germans, the Greek government had previously been reluctant to accept large-scale British assistance.

The Greek Army, commanded by Gen. (later Field Marshal) Alexander Papagos, had a total effective strength of 430,000 men. Unlike the Yugoslav Army, it was fully mobilized and to some extent battle tested. Its problem in countering a German attack was complicated by the psychological and political necessity of defending the long northern frontier. The army command believed that it could not voluntarily evacuate Albania, since to do so would seem to concede victory to the Italians. On the other hand, it was convinced that national morale would be equally damaged if it were to give up the long tongue of Greek territory extending east of Salonika. There the Metaxas Line covered the Bulgarian border. Built only for use in the event of a war with Bulgaria, the line could not withstand a German attack, but it had cost a great deal of money and in the popular mind had become a symbol of national security. The British commander, Lt. Gen. (later Field Marshal) Sir Henry Maitland Wilson (later 1st Baron Wilson of Libya and of Stowlangtoft) lacked sufficient troops to close the gap between the front in Albania and the Metaxas Line, and he therefore placed his forces in a short line facing northeastward along the Vermion Mountains and the lower Aliakmon River. Apparently, neither the Greeks nor the British had decided on a course of action if the Germans attacked across the virtually undefended Yugoslav border, and it was just there that one or two thrusts would outflank all three segments of the Greek-British front.

The German Twelfth Army, under Field Marshal Wilhelm List, executed the campaign in Greece. It had three corps headquarters commanding 12 divisions. In the assembly one corps was stationed southwest of Sofia, to attack toward Skopje (Skoplje) in southern Yugoslavia and then southward into Greece. The second was placed in the southwest corner of Bulgaria to attack through and around the flank of the Metaxas Line toward Salonika, and the third was moved close

Map 26. FALL OF YUGOSLAVIA AND GREECE (April 6-30, 1941). Yugoslavia's refusal to allow German troops and supplies destined for Turkey to pass over her railroads brought on a German invasion. Yugoslav forces were only partially mobilized, and were strung along an extensive frontier. The few trained and equipped units offered stiff resistance in their limited sectors, but the key cities were soon captured by the stronger German forces, and the Yugoslav troops were dispersed or captured.

Benito Mussolini's Greek venture had resulted in the entrance of British ground and air forces into Greece, in accordance with an Anglo-Greek mutual aid agreement. Adolf Hitler's last desire was to have British bombers within range of the Ploesti oil fields, his chief source of supply. He therefore decided to conquer Greece and expel the British. The advance through Yugoslavia had opened the way for his troops to attack the exposed flanks of the Greek and British positions, and the occupants were soon forced to withdraw. The Greeks were cut off and made to surrender; a large proportion of the British troops were evacuated to the island of Crete.

to the eastern end of the Greek-Bulgarian border. The heavy concentration against the narrow strip of territory east of Salonika resulted mainly from Hitler's desire to defeat at the outset any British attempt to retain a foothold in northern Greece or on the Aegean Islands, Thasos, Samothrace (Samothrake), and Lemnos.

The Twelfth Army attacked on April 6. The units moving toward Skopje encountered the fully mobilized Yugoslav Third Army and became involved in heavy fighting, as did those attacking the Metaxas Line frontally, but everywhere the offensive made good progress. On April 9, Salonika fell, and the Greek Second Army surrendered, thereby ending resistance on the Metaxas Line and in all the territory east of Salonika.

The German corps advancing through southern Yugoslavia took Skopje on April 7, and began turning south. On April 10, it attacked through the Bitolj (Monastir) gap between the open flanks of the British line along the Vermion Mountains, and the Greek front in Albania. The British immediately began retreating toward Mount Olympus (Olymbos), and the next day the Greek First Army decided to withdraw southward from Albania. When the Germans took Metsovon Pass on April 21, the First Army's route of escape from the area around and north of Ioannina was cut. The army surrendered the next day. The British force retreated southward along the Aegean coast

toward Athens (Athenai). The Germans took the city and reached the Isthmus of Corinth on April 27, and in three more days occupied the Peloponnesus (Peloponnesos). Most of the 12,000 British casualties were incurred during these last days, when the German ground forces closed in, and the ships evacuating the troops were forced to come toward shore without air cover. The Germans lost 1,100 men killed and 4,000 missing and wounded.

Greece was liberated by British troops from the Mediterranean theater in late 1944 (see section 8. *Mediterranean Operations*), and Yugoslavia was cleared of German troops during the Russian final offensive in 1945 (see section 6. *German Invasion of the USSR*). 8. Mediterranean Operations

This section covers not only operations in the Mediterranean theater itself, but also the British campaign against the Italians in East Africa and

military activities in Iraq and Iran, which are inseparable from operations in the Mediterranean proper. Since naval and air warfare are considered separately (see sections 12. *Developments in Naval Warfare* and 13. *Developments in Air Warfare*), the emphasis is on the land campaigns in Egypt, Libya, East Africa, French North Africa, Crete, Syria, Italy (including Sicily), and numerous Mediterranean islands.

The Mediterranean theater varied in importance as World War II progressed. Before the entry of Italy in June 1940 it was inactive; from that time onward, until the German attack on the USSR in June 1941, it was the main operational area and the only one where there was fighting on land. With the Anglo-American landings in French North Africa in November 1942 (Operation Torch) until August 1943, when plans for the invasion of northwestern Europe (Operation Overlord) were approved by the Combined Chiefs of Staff, it assumed increasing significance, but when Overlord was mounted in June 1944, the Mediterranean became a secondary theater.

Background to Conflict: 1933-1939.—The six and one-half years after Adolf Hitler became chancellor of the German Reich in January 1933 were a period of mounting tension in the Mediterranean and nearby areas as in other regions. In October 1935, Italy, correctly judging the impotence of the League of Nations, decided to extend her already considerable empire in Africa by invading Ethiopia, and by May 1936 she had completed the annexation of the country.

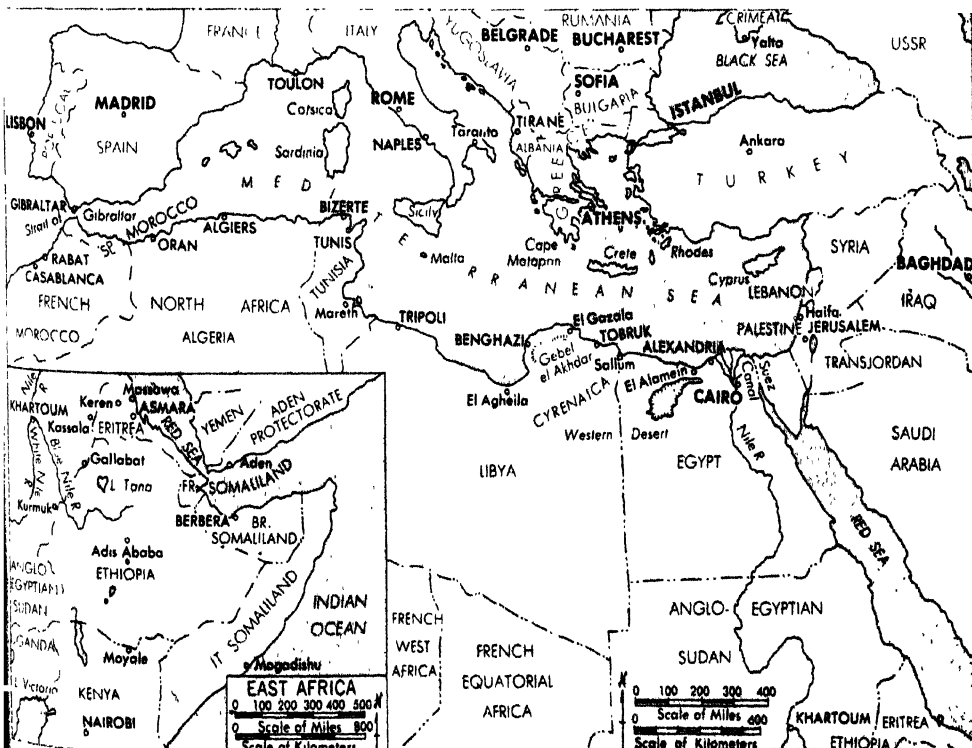

Later that year, on August 26, Anglo-Egyptian relations were put on a more satisfactory basis by the conclusion of a treaty, the effect of which was that in war Egypt would be Britain's

ally. The Suez Canal was to be safeguarded by the continued presence of a British force, but to assuage Egyptian susceptibilities the troops were to be confined to a narrow zone along the canal itself. The British were also to enjoy certain harbor and dock facilities and the use of railway and road communications.

The somewhat loose alliance between Germany and Italy subsequently known as the Rome-Berlin Axis was concluded on October 25. On Jan. 2, 1937, British and Italian relations were eased by the signing of a joint declaration (known ironically as the Gentlemen's Agreement), the main clause of which recognized freedom of movement for both parties in the Mediterranean. The declaration was reaffirmed in April 1938, when the two governments also agreed to exchange information annually concerning any major changes or proposed changes in the strength and dispositions of their respective armed forces. Just at this time, Britain's position in the Middle East was complicated by unrest in its mandate of Palestine, where open rebellion had broken out. A year later, on April 7, 1939, Italy invaded Albania, and within a short time occupied the whole country.

Meanwhile, Hitler's various acts of aggression, culminating in the invasion of Czechoslovakia in March 1939, and his threatening attitude toward Poland were bringing Europe to the brink of general war. Under an agreement announced on August 25, Britain guaranteed that it would go to the assistance of Poland in the event of German aggression. Germany invaded Poland on September 1, and two days later, Britain and France declared war on Germany. By September 10, the other members of the British Common-

Map 27. MEDITERRANEAN THEATER OF OPERATIONS.

wealth of Nations had made similar declarations. See also section 2. *Between World Wars*.

CAMPAIGNS IN AFRICA

French and British staff conversations, which began in London at the end of March 1939, included the broad outline of plans for conducting joint operations in the Mediterranean. Later, in May and June, meetings between British and French commanders in the Mediterranean and the Middle East were held at Rabat, Aden, and Jerusalem.

With the outbreak of war between Germany and the Allies on Sept. 3, 1939, Italy found herself in a difficult position. She had an extensive African empire, consisting of the older colonies of Eritrea, Italian Somaliland, and Libya and the more recently acquired Ethiopia. Even if her Axis partner gained early successes in northern Europe, Italy's communications with her African possessions would be cut except for the occasional ship or aircraft which might make a hazardous journey. The British and French navies dominated the Mediterranean with powerful fleets based on British naval bases at Gibraltar, Malta, and Alexandria and on French bases at Toulon, Bizerte, Algiers, and Oran. In Libya the Italian garrison was sandwiched between strong French forces in French North Africa and considerable British forces in Egypt; and Italy's other colonies were surrounded by potential enemies on all sides, although the forces arrayed against her were not very formidable in the early stages of the war. Under these conditions the Italian dictator, Benito Mussolini, adopted the only practical course of remaining nominally neutral while giving all possible support to Germany.

With Italy neutral and Germany without access to the area (except for an occasional submarine that might slip through the narrow Strait of Gibraltar), the Mediterranean theater remained inactive for the first nine months of the war. During this period the Allies took steps to improve their position and perfected their plans for joint action in the event of a hostile Italy. In June 1939, Lt. Gen. (later Field Marshal) Sir Archibald Wavell (later 1st Earl Wavell) was appointed commander in chief of all British land forces in the Middle East with headquarters in Cairo. The first contingents of Australian and New Zealand troops arrived in Egypt to reinforce his command in February 1940.

On May 10, Winston Churchill became prime minister and minister of defense, and on the same day, Hitler's armies invaded France, Belgium, the Netherlands, and Luxembourg. German success was spectacular. By June 22, France had signed an armistice with Germany, and hostilities had ended; the British Expeditionary Force had withdrawn to the United Kingdom; and the northern half of France and all of Belgium, the Netherlands, and Luxembourg became German-occupied countries. Meanwhile, on June 10, Italy had declared war on Great Britain and France (effective June 11). France also signed an armistice with Italy, on June 24, and the British Commonwealth was then alone in arms against Germany and Italy.

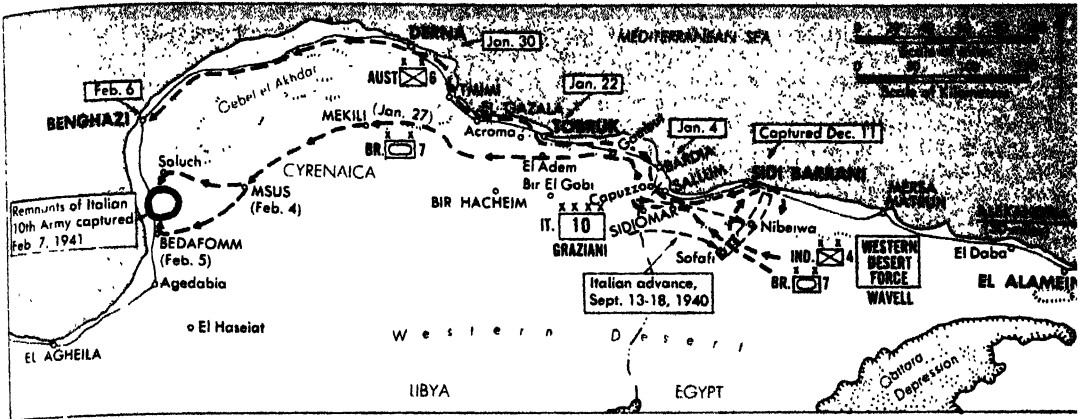

The effect of these events on the Mediterranean theater was alarming from the British point of view. The authorities in French North Africa, the other French African dependencies, and Syria decided to recognize the new French government at Vichy under Marshal Philippe

Pétain and to obey his orders. The carefully laid Anglo-French plans for joint action had collapsed. The burden of keeping open sea communications in the Mediterranean, defending the Suez Canal, and dealing with the Italians in East Africa now fell entirely on the British Navy and on General Wavell's scanty forces centered in Egypt.

As of the beginning of June, the Commonwealth had 1 battleship, 1 six-inch cruiser, and 4 destroyers based on Gibraltar, and 4 battleships, 8 six-inch cruisers, 1 aircraft carrier, and 21 destroyers in the eastern Mediterranean based on Egypt, while Italy had 6 battleships (2 of which did not join the fleet until July), 7 eight-inch cruisers, 12 six-inch cruisers, and 50 destroyers. Commonwealth land forces included 1 armor division, 1 incomplete Indian division, 1 New Zealand brigade, 1 horsed cavalry division, part of an Australian division, 2 independent cavalry regiments, 19 British infantry battalions, and 4 artillery regiments, totaling about 63,500 troops in Egypt and Palestine; and about 9,000 troops in the Sudan, 1,500 troops in British Somaliland and 8,500 troops in Kenya, or a total of about 19,000 in East Africa. Italy had 9 metropolitan (regular) divisions, 3 Black Shirt divisions, and 2 Libyan native divisions, totaling about 200,000 troops in Libya; and about 91,000 European and 199,000 native troops, with 400 guns and 200 light tanks, in East Africa. The Commonwealth units were generally considerably under strength, but those of the Italians were at full strength. British Commonwealth aircraft of all types numbered 375 (205 in Egypt and Palestine and 170 in East Africa); Italian aircraft, 633 (313 in Libya and 325 in East Africa).

In addition to General Wavell, the principal commanders on the British Commonwealth side were Adm. (later Admiral of the Fleet) Sir Andrew Cunningham (later 1st Viscount Cunningham of Hyndhope) and Air Chief Marshal Sir Arthur Longmore, in charge, respectively, of naval and air operations in the Mediterranean and Middle East. Gen. (later Field Marshal) Sir Henry Maitland Wilson (later 1st Baron Wilson of Libya and of Stowlangtoft) was in command of British troops in Egypt; Lt. Gen. (later Gen. Sir) Richard N. O'Connor, of the Western Desert Force; Lt. Gen. (later Gen. Sir) William Platt, of troops in the Sudan; and Lt. Gen. Douglas P. Dickinson, of the East African Force, based on Kenya. General Dickinson was replaced by Lt. Gen. (later Gen. Sir) Alan G. Cunningham, younger brother of Admiral Cunningham, on November 1. On the Italian side Marshal Italo Balbo, who was killed in an air accident in June, was succeeded as commander in chief in Libya by Marshal Rodolfo Graziani. The duke of Aosta served as viceroy and commander in chief in Italian East Africa.

First British Offensive in North Africa: June 1940–February 1941.—The first clash between British and Italian forces took place in the Western Desert in the early hours of June 11 before the Italian troops concerned had been told of the declaration of war. During the next six months the British carried out many small raids against Italian positions in Libya. In addition there were numerous patrol clashes in which the superiority of the British Commonwealth troops became apparent. On July 3, the British Navy sank or put out of action a number of units of the French Fleet at Oran and Mers-el-Kebir in

Map 28. ITALIAN DEFEAT IN LIBYA (Sept. 13, 1940–Feb. 7, 1941). In mid-September 1940, Marshal Rodolfo Graziani marched his huge Italian army across the Libyan border into Egypt. Though outnumbering the British by five to one, he advanced only as far as Nibeiwa and Sidi Barrani, and established defensive positions on a line through the two villages. On December 9, the British launched an offensive that was to carry them 500 miles across northeastern Africa. (The term "Western Desert," used to designate the portion of the Libyan Desert in Cyrenaica and Egypt in which the fighting took place, is sometimes confined to the western frontier area of northern Egypt.) Key points along the coast fell on the dates shown, each with a sizable bag of Italian prisoners. What remained of the Italian Tenth Army was rounded up and captured south of Benghazi on Feb. 7, 1941. The British then advanced outposts to El Agheila. It was a spectacular British performance. Though greatly outnumbered, they captured 130,000 prisoners and many tanks, artillery pieces, and vehicles at very small cost to themselves. A sudden need to send troops to Greece deprived Gen. Sir Archibald Wavell of the opportunity to capture the principal Italian base at Tripoli and drive the Italians from Africa.

order to prevent their falling into German hands. French warships at Alexandria were immobilized on the following day. Later, on September 23–25, British and Free French forces failed in an attempt to land at the Vichy French port of Dakar but succeeded in badly damaging the battleship *Richelieu*. Meanwhile, between September 13 and September 18, the Italians advanced in strength approximately 60 miles into Egypt but halted at Maktila, east of Sidi Barrani. It was a disappointment to the British that they did not advance farther, for plans had been made to deal them a heavy blow with the 7th Armored Division as they approached Matruh. During the advance the Italians lost more than 3,000 men; the British, about 150.

On October 28, Italian troops based on Albania invaded Greece. A fortnight later, on November 11, the British Fleet Air Arm attacked the Italian Fleet at Taranto and, for a loss of two aircraft, put half of its major units out of action for about six months.

In December, the Western Desert Force, consisting of the 7th Armored Division and the Indian 4th Division, began the first major British offensive in North Africa. Operations were under the direction of General Wavell, with General O'Connor in executive command. The offensive began on December 9, and by December 11, Sidi Barrani had been taken with a loss to the Italians of 38,300 prisoners. Important decisions now had to be made. The offensive had been planned to last no more than five days and to stop after the capture of Sidi Barrani. Its success had greatly exceeded expectations, and General Wavell, urged by General O'Connor, agreed to the continuance of the advance. Arrangements had been made, however, to send the Indian 4th Division to East Africa, where it was required for offensive operations: shipping was already standing by at Suez to carry it to Port Sudan. The Indian division was therefore withdrawn from the Western Desert Force on December 14,

and replaced immediately by the Australian 6th Division, but the exchange caused a delay in the resumption of the offensive.

Successes followed in quick succession. Bardia was captured on Jan. 4, 1941 (32,000 prisoners were taken), and Tobruk on January 22 (about 25,000 prisoners). By this time the Italian Tenth Army (together with considerable reinforcements sent from the Fifth Army in Tripolitania) had been greatly depleted in strength, and General O'Connor decided on a bold step to complete the destruction of the Italian forces in Cyrenaica. This plan required the 7th Armored Division to make a desert march to Beda Fomm near the coast with a view to getting behind and cutting off the remaining Italian troops, while the Australian 6th Division was to advance on Benghazi by the coastal route. This operation was completely successful. The 7th Armored Division reached Mechili (El Mechili) on January 27, Msus on February 4, and the Beda Fomm area on February 5. Meanwhile, the Australian 6th Division, having captured Derna on January 30, advanced on Benghazi, which it reached on February 6. After some brisk fighting at Beda Fomm, in which gallant efforts were made to break through the British positions, the Italians surrendered on the morning of February 7. There were about 25,000 prisoners, including Gen. Giuseppe Tellera, commander of the Tenth Army, who was mortally wounded. Immediately after the surrender a small protective group was established at El Agheila, with patrols out for 40 miles along the coast toward Sirte.

The campaign had been a remarkable success. The 13th Corps (as the Western Desert Force was renamed on Jan. 1, 1941) had never exceeded a strength of 31,000 men. Between Dec. 9, 1940, and Feb. 7, 1941, it had advanced more than 500 miles and captured more than 130,000 prisoners, about 400 tanks, nearly 850 guns, and thousands of wheeled vehicles. The 13th Corps'

own losses were about 500 killed, 1,373 wounded, and 55 missing.

With the destruction of the Italian Tenth Army and the occupation of the whole of Cyrenaica, the British were faced with a difficult problem. The only Italian forces left in North Africa were 5 very weak and dispirited divisions of the Fifth Army around the port of Tripoli. General O'Connor was confident that the 13th Corps could advance and capture Tripoli, with the prospect of eliminating all Axis forces from North Africa, and he immediately drew up plans for doing so. There was, however, another urgent call in a very different direction. When the Italians began invading Greece, they had met with some initial success, but very soon the Greeks counterattacked and drove them back into Albania. Partly to help their ally and partly for other reasons, the Germans decided to advance through Yugoslavia and occupy Greece. German preparations for this move had been apparent to the British intelligence service for some time. Hitherto the Greeks had declined British aid, but on Jan. 29, 1941, Premier Ioannes Metaxas died, and his successor, Alexandros Korizis, intimated that he would welcome British help against what he regarded as an imminent German threat. British resources in the Middle East were insufficient to allow both an advance to Tripoli and aid to Greece. After numerous exchanges of views between the British government and General Wavell and discussions in Cairo and Athens (Athenai), which were attended by Foreign Secretary Anthony Eden and the chief of the Imperial General Staff, Gen. (later Field Marshal) Sir John Greer Dill, it was decided to send a force to Greece and remain on the defensive in North Africa.

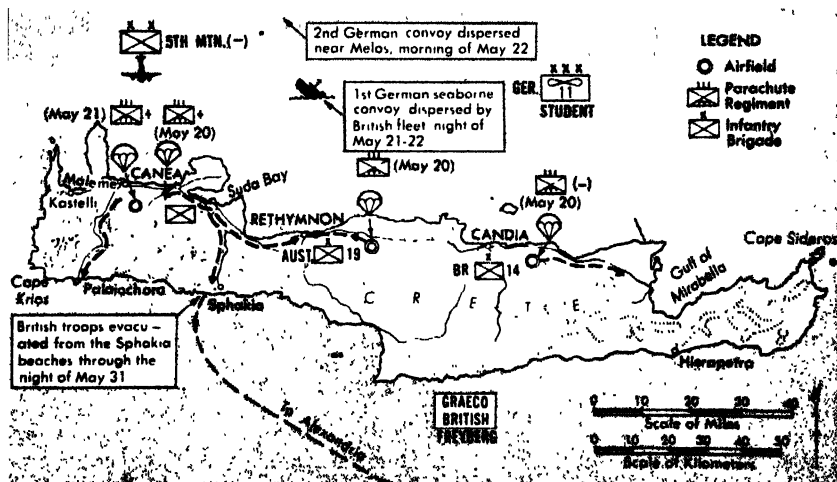

British Expedition to Greece and Crete: April-May 1941.—The force sent to Greece was commanded by General Wilson and consisted of about 24,200 British (including an armored brigade), 17,100 Australian, and 16,700 New Zealand troops. The dispatch of British troops from Egypt began on April 5, and on the following day, German forces invaded Yugoslavia and Greece. By April 16, British and Greek forces had been withdrawn to a front south of Mount Olympus (Olympus). In the face of superior German forces and of an Italian offensive from Albania, the situation deteriorated

rapidly. The decision was made to withdraw British Commonwealth forces from Greece, and the withdrawal was carried out between April 24 and May 1. Meanwhile, on April 27, German troops entered Athens.

From the outset the British authorities had realized the risks involved in the Greek venture, but the political advantages were thought to outweigh the military hazards. Viewed in the light of later knowledge, it seems that the chances of success were remote in the extreme. The expedition was hurriedly planned, the headquarters was an improvised one, the troops were not the most experienced or the best trained, and the Greeks, although brave, were ill equipped. The expedition cost the British approximately 12,000 casualties. In contrast, the German invasion of Greece was carefully planned and made in considerable strength, with well-equipped and well-trained troops. The Greek expedition deprived the British of the chance of seizing Tripoli and of expelling the Italians from North Africa.

Following the decision to evacuate British troops from the Greek mainland, the question arose as to whether Crete should be held. Prime Minister Churchill insisted that it must be held, and on April 30, General Wavell flew to the island to discuss plans for its defense. Maj. Gen. (later Lt. Gen.) Bernard Freyberg (later 1st Baron Freyberg), commander of the New Zealand Division, was placed in command. By May 3, he had disposed his troops as follows: the 14th Infantry Brigade at Candia (Herakleion), the Australian 19th Brigade at Rethymnon (Retimo) and Georgeopolis, a composite force of 14,800 men in the Suda Bay-Canea (Khania) area, and two brigades of New Zealanders in the Maleme Airfield sector. In addition, Greek battalions were distributed among the various sectors. The total strength was about 42,500 troops. Many of them had recently been fighting on the mainland, some were comparatively untrained administrative personnel, and there was an acute shortage of arms and heavy equipment.

Under the direction of Gen. (later Col. Gen.) Kurt Student and the executive command of Col. Gen. Alexander Löhr, the Germans decided to attack and capture the island mainly with airborne troops. The aircraft available consisted of about 500 serviceable bomber, fighter, and reconnaissance planes, about 500 transport air-

Map 29. GERMAN AIRBORNE INVASION OF CRETE (May 20-31, 1941)

Following the conquest of the Greek mainland, Adolf Hitler decided to capture the island of Crete. After a week's bombardment of Allied positions, German paratroops landed as shown, closely followed by airborne troops. The defenders were gradually forced away from the airfields and key points; eventually most were evacuated from the island. The British Fleet destroyed or dispersed the two German ship convoys, but not without considerable loss and damage by German air attacks. Though the operation was a striking success, the heavy German losses turned Hitler against airborne operations, which were neglected by the Germans thereafter.

craft, and 72 gliders. The bombing of Allied positions and installations began on May 14, and the first airborne troops landed on May 20. The capture of Maleme Airfield on the following day enabled the Germans to fly in reinforcements rapidly. As the Germans built up their strength, the British position gradually deteriorated. By May 24, General Freyberg had abandoned hope of holding Crete, and, in view of the heavy losses being suffered by the Royal Navy, the decision to evacuate the island was made on May 27. Severe losses were sustained in attempts to embark troops from the northern parts of the island. The last evacuation was made from a beach at Sphakia (Chora Sphakion) on the south coast on May 31. Allied casualties in the campaign were about 17,500 killed, wounded, and prisoners; German losses, just over 6,000. In addition, 9 British warships were sunk, and 17 were damaged.

For a more detailed account of operations in Greece in 1941, see section 7. *Balkan Campaigns.*

Iraq and Syria: April-June 1941.—In 1941, Italy's ally, Germany, began to interest herself in Iraq and French-held Syria. On April 3, a pro-German politician, Rashid 'Ali al-Gailani, brought off a successful coup d'état in Iraq. At the same time, reports reached General Wavell that German cadres of officers and technicians were arriving in Syria in French aircraft.

On April 17, an Indian brigade was sent to protect the oil pipeline running from Iraq to Haifa. British Commonwealth forces engaged the insurgent forces in Iraq on May 2, and on May 31 occupied Baghdad. The pipeline was secured, and the regent, Emir 'Abdallah, was reinstated.

By June 8, it was clear that German forces had infiltrated into Syria in some strength, and that the Vichy commander, Gen. Fernand Dentz, was supporting them. In the next six days, British Commonwealth forces under General Wilson advanced into Syria and, in a sharp campaign, defeated the Vichy forces and occupied the country.

East Africa and the Red Sea: June 1940–November 1941.—Because of the negligible strength of British forces in East Africa, the four months following Italy's declaration of war saw a number of Italian successes. In the Sudan, Italian troops occupied the frontier towns of Kassala and Gallabat on July 4, 1940, and in Kenya they captured Moyale on July 15. Then, between August 5 and August 19, they occupied British Somaliland.

By November 1940, the British were able to adopt a more aggressive attitude, though still on a limited scale, and by February 1941 they were in a position to mount a large-scale offensive. The situation was also greatly improved by the growth of a considerable patriot movement in Ethiopia, where native forces organized by Maj. (later Maj. Gen.) Orde C. Wingate and other British officers were increasing rapidly in strength and efficiency. At the time the offensive started, the Indian 4th and 5th divisions were stationed in the Sudan. In Kenya the units were more diversely organized and of more varied composition. Of the 77,000 troops in the area, 27,000 were European South Africans; 6,000, Europeans serving in East and West African forces; 33,000, East Africans; 9,000, West Africans; and 2,000, of various nationalities.

The British plan called for an advance eastward from the Sudan through northern Ethiopia

to Eritrea and the Red Sea, together with an approximately simultaneous advance northward from Kenya through southern Ethiopia to the capital, Addis Ababa, and also eastward from Kenya to Italian Somaliland. The terrain in many parts of this area affords a striking contrast to the Western Desert. Much of Ethiopia is mountainous with wide and torrential rivers. The country favors highly trained troops, and it also gave the Ethiopian guerrillas full scope.

The British offensive started early in February. Progress was rapid, and the various columns inflicted heavy losses on the Italian troops and took large numbers of prisoners. By February 25, forces from Kenya had captured most of Italian Somaliland, including the ports of Kismayu and Mogadishu. A force from Aden, escorted by warships, landed at Berbera on the coast of British Somaliland (Somaliland Protectorate) on March 16. On April 6, Addis Ababa was occupied. Meanwhile, forces from the Sudan captured Keren, Eritrea, on March 27, and by April 4 the area between Lake Tana and Addis Ababa had been occupied. Masawa was occupied on April 8. On May 16, after stubborn fighting, the duke of Aosta surrendered at Amba Alagi (the formal surrender took place on May 20). Organized resistance ended, but isolated detachments continued to fight for some months, and it was not until November 27 that Gondar, the last place to hold out, surrendered.

The two most important battles of the East African campaign were those fought at Keren and Amba Alagi. The British land forces were well supported by the air force. Typical of this assistance were the attacks made by the South African Air Force on the airfield at Addis Ababa on April 4, 5, and 6, when about 30 Italian aircraft were destroyed.

All of the Italian forces, white and native, who had not been killed or who had not deserted (as many of the native troops had) became prisoners of war. Total Italian losses were estimated at 289,000. There had at times been serious fighting, but it is true to say that, from the British point of view, the East African campaign was a struggle against the climate and disease rather than against the Italian enemy. Between June 1940 and May 1941, British Commonwealth troops suffered only 1,154 battle casualties but 74,550 cases of sickness or accident, of which about 10,000 were due to dysentery and 10,000 to malaria; 744 of these died.

In East Africa as in other campaigns, Italian arms had not prospered. The campaigns in Africa, as well as that against the Greeks in Albania, had shown Italian troops to be poorly led and trained. They were badly equipped, especially in tanks, and logistically ill found. In Africa they had been completely defeated in two campaigns by British Commonwealth forces of greatly inferior strength. Not less than 420,000 Italians (including Italian-trained native troops) had been killed or captured, as compared with approximately 3,100 British Commonwealth battle casualties. The Italians also lost hundreds of tanks, guns, trucks, and aircraft and vast quantities of other equipment and stores. The collapse in East Africa was Italy's third serious defeat since entering the war. By early February 1941, she had been decisively beaten in Cyrenaica. By mid-March, her last effort to defeat the Greeks without German aid had failed. For the British the campaign in East Africa was the last of the easy victories. Thereafter they were to meet Germans, who were well led,

well trained, and well equipped.

Arrival of the Germans in North Africa: February 1941–May 1942.—After the Battle of Beda Fomm in February 1941, the bulk of the British forces in the Western Desert were withdrawn in preparation for the expedition to Greece. The defense of Cyrenaica was then left to the Australian 9th Division and part of the 2d Armored Division. Later the Indian 3d Motor Brigade was sent to the desert as a reinforcement. This force, which was much less experienced than the Australian 6th Division and the 7th Armored Division which it had replaced, was under the command of Lt. Gen. (later Sir) Philip Neame.

Up to this time the Germans had participated in the Mediterranean operations only in the air (since early January, the Luftwaffe had made attacks on British warships and convoys from Italian airfields). The predicament of the Italian forces in North Africa after their serious defeats in Cyrenaica, however, had convinced the German High Command that a substantial force must be sent to the assistance of their Axis partner. The decision to do so had been made on January 11, and on February 5 the formation of the German Africa Corps was made known to the Italians. The new corps, which was to consist of the 5th Light Motorized Division and the 15th Panzer Division, was placed under the command of Lt. Gen. (later Field Marshal) Erwin Rommel. Within three months, German efficiency and equipment and Rommel's skill in armored warfare, combined with the reduction in British strength, were to change the whole position in North Africa and see the British driven back to the Egyptian frontier.

Rommel arrived in Tripoli on February 12, and at once began organizing the defenses of the area with such Italian troops as were available and making plans for offensive action as soon as the Africa Corps arrived. General Wavell and his intelligence staff estimated that Rommel would not be able to stage a major offensive before May 1. In this they were wrong. In early March, there were a number of clashes between the opposing light forces in the El Agheila area. Then, on March 24, Axis forces occupied El Agheila, and on April 1 they took Mersa Brega. Thereafter their advance was rapid. The weak British forces were outmaneuvered and thrown into confusion. On April 3, Benghazi fell, and on April 7, Generals O'Connor and Neame were captured by a German reconnaissance unit. Me-kili was taken the next day, and by April 11, Axis forces had reached Bardia and Sallum. In the face of this serious threat to the Suez Canal, General Wavell had decided to hold the port of Tobruk with the Australian 9th Division, the Australian 18th Brigade, and some armored and other ancillary units. Their task was facilitated by the existence of the old Italian defense works on the landward side, which were still in fairly good condition. By April 11, Tobruk had been invested, but the speed with which Rommel's forces pressed on past the port made it apparent to Wavell that the Axis objective was the Suez Canal, and that it was necessary to make a stand somewhere in the neighborhood of the Libyan-Egyptian frontier. The reconstituted Western Desert Force, consisting of all the troops Wavell could make available, was put under the command of Lt. Gen. Sir Noel M. de la P. Beresford-Pease; it comprised the Indian 4th Division, the

Australian 7th Division, the incomplete 6th Division, and a mobile force equivalent to a brigade.

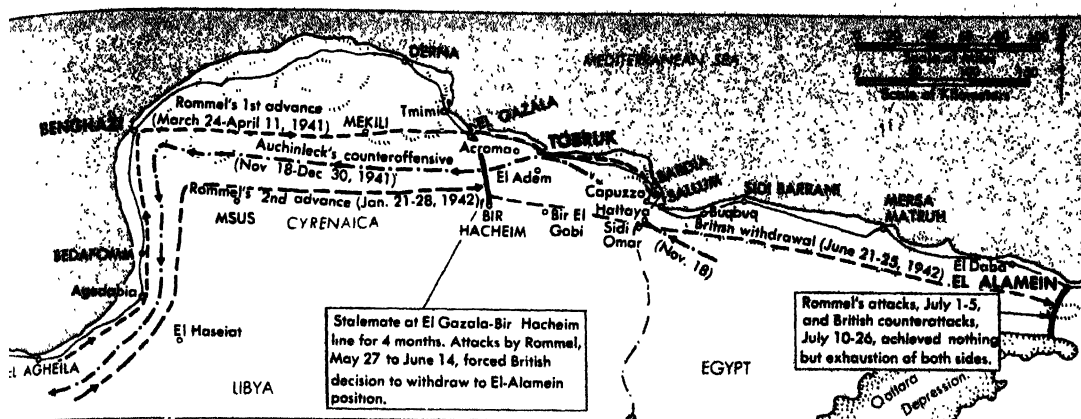

Between April 13 and April 17 and again between April 30 and May 4, Axis troops unsuccessfully attacked Tobruk. Meanwhile, British defenses along the Egyptian frontier had been organized, and it soon became clear that this factor, combined with the threat to their flank from Tobruk and logistic difficulties, had brought the Axis offensive to a halt. Between May 15 and May 17, the British carried out a local offensive in the Halfaya-Sallum-Capuzzo area. Although this offensive was partially successful, the Germans recaptured Halfaya on May 27.

Meanwhile, on May 12, a sea convoy code named Tiger had arrived in Egypt with 82 cruiser tanks, 135 infantry tanks, and 21 light tanks, and this made it possible to start rebuilding the 7th Armored Division. By the end of the month, the British forces had been reorganized and reequipped sufficiently to assume the offensive, and on May 28, General Wavell issued orders for Operation Battleaxe. The Western Desert Force was to defeat the enemy on the frontier and occupy the Bardia-Sallum-Capuzzo-Sidi Azeiz area, then attack the enemy around Tobruk and relieve the port, and finally move on Derna and Mekili. The forces available were the 7th Armored Division, the Indian 4th Division, the Indian 11th Infantry Brigade, and the 22d Guards Brigade. Axis forces consisted of the 15th Panzer Division in the frontier area, with three Italian infantry battalions around Capuzzo and the rest of the weak Trento Division and Bardia.

The attack began on June 15 and achieved some initial success, but on the following day progress was slow, and further advance was checked by enemy counterattacks. By the morning of June 17, losses in tanks and the generally unfavorable situation made it clear that the attack had failed. The order to withdraw was given, and the British forces retired to their original area. British casualties totaled about 960. Of 90 cruiser and about 100 infantry tanks which began the battle, 27 cruisers and 64 infantry tanks were lost. The air force lost 36 aircraft. The Axis forces sustained about 800 casualties, mostly Germans. They had 12 tanks destroyed and about 50 damaged; and they lost 10 aircraft.

The British failure in Battleaxe was attributable to the haste with which it was mounted, the lack of opportunity to train the troops with new equipment, and the lack of tactical training, especially in armored units. Cooperation between air and ground forces also left much to be desired. The Axis defenders occupied well-prepared positions and showed marked skill in handling their antitank weapons and in staging counterattacks. It was clear to the British that a much greater effort was required if the Axis forces were to be eliminated from North Africa. The next six months were to be a period of preparation by both sides. Meanwhile, on June 22, Germany attacked the USSR, and Prime Minister Churchill at once acclaimed the Soviets as an ally with whom his country would cooperate to the fullest extent.

On July 5, General Wavell was replaced as commander in chief in the Middle East by Gen. (later Field Marshal) Sir Claude J. E. Auchinleck. It would be hard to imagine a more difficult military task than that which had faced General Wavell during his two years in command. With the entry into the war of Italy and the

Apr 30. BRITISH AND AXIS OPERATIONS IN LIBYA AND EGYPT (March 24, 1941-July 26, 1942). The map shows schematically the British and Axis seesaw operations during the period covered. Vast distances across the sandy wastes posed problems of vehicle maintenance and of supply (water was a major one) that had marked effect on the conduct of operations. As one force fell back on its base, it became relatively stronger; meanwhile, logistical problems made the opponents progressively weaker as they moved farther and farther from their own base. At the end of the exhausting operations in July 1942 along the El Alamein line, Field Marshal Erwin Rommel was in a most hazardous position, logistically and strategically.

all of France, he found himself with totally inadequate forces, imperfectly trained and not fully equipped. He was outnumbered on all fronts. In less than 12 months he had completely defeated the Italians in North Africa and East Africa, and had killed or captured more than 400,000 of the enemy at a cost of just over 3,000 British Commonwealth casualties. These results were attained despite distractions in Syria and Iraq. In April, on political grounds, he was compelled to send a large force to Greece, but in spite of this contingency and the arrival of the German Africa Corps in North Africa, he succeeded in carrying out his main task, which was the defense of the Suez Canal. Those Allied commanders who came to the Middle East and the Mediterranean later never experienced the same difficulties: their resources in men and materials were incomparably greater.

During the summer of 1941 there was little change in the dispositions of either side. Planning for the next British offensive, known as Operation Crusader, began in August. On September 18, the Western Desert Force was redesignated the Eighth Army and placed under the command of General Cunningham, who had earned such a high reputation in East Africa. Meanwhile, in July, there were reports of German intrigues in Iran, and on August 17, a joint Anglo-Soviet note was sent to the Iranian government. British forces from India entered the country on August 25. There was some resistance at first, but it ceased by August 28. At about the same time, Soviet forces entered Iran from the north, and on September 17, British and Soviet troops occupied Teheran, the capital. The occupation of Iran prepared the way for the development of a supply route to the USSR. While these events had no influence on the war in the Mediterranean, the denial to the Germans of access to that part of the world relieved General Auchinleck of any anxiety from that quarter.

By the beginning of November, plans had been completed for Operation Crusader. The twofold objective of the operation was the relief of Tobruk and the occupation of the whole of Cyrenaica, to which General Auchinleck added the rider that this must be accompanied by the

destruction of the enemy's armor. The British Eighth Army (including the Tobruk garrison) consisted of 1 armored division, 3 armored or tank brigades, and the equivalent of 6.5 infantry divisions, or about 118,000 troops. There were about 680 British tanks, with 500 tanks in reserve or on the way to North Africa. The Axis forces comprised 2 German and 1 Italian armored divisions and 1 German and 6 Italian infantry divisions, or about 119,000 troops. There were about 390 German and Italian tanks, with practically no reserves. The German-Italian numerical inferiority in armor was in some respects compensated by the superiority of their best tanks in performance and gun power. The real superiority of the Axis lay, however, in antitank guns that fired a much heavier missile than the British 2-pounders, had a much longer range, and were handled with great skill.

The offensive began on November 18. The first attempt to relieve Tobruk failed, and British losses in armor were heavy. On November 26, General Auchinleck relieved General Cunningham of command of the Eighth Army on the ground that his plans for the future were not sufficiently aggressive. Cunningham was replaced by Maj. Gen. (later Gen. Sir) Neil M. Ritchie, who had been deputy chief of staff in the Middle East. The offensive was resumed on December 5, and on December 10, Tobruk was relieved. The Axis forces withdrew from El Gazala on December 16, and on December 24, British troops entered Benghazi, having advanced about 300 miles. There the offensive ended. The Eighth Army had attained its first objective, the relief of Tobruk. It had also occupied Cyrenaica, although the occupation was to be a fleeting one. It destroyed many Axis tanks, but its own losses were also very heavy. The German Africa Corps showed remarkable powers of recovery, and on Jan. 21, 1942, Rommel resumed the offensive. By January 28, the British had withdrawn from Benghazi to the El Gazala-Bir Hacheim line. There was then a lull in the Western Desert until the end of May.

Since Operation Crusader began in November 1941, British casualties had totaled about 17,700, and those of the Axis about 38,300. Tank losses

Camera Press-Pix

Residents of Malta take shelter in an underground gallery during one of the numerous Axis air attacks. Because of their bravery, the island was awarded the George Cross.

are more difficult to assess accurately. Up to December 12, the 7th Armored Division suffered 526 battle casualties and breakdowns in tanks, of which about 281 became battleworthy again. How many again took part in Crusader is not known. In addition, more than 200 British infantry tanks became casualties, although many of these were eventually recovered and used again. Axis losses in tanks were around 340, many of which were recovered and repaired. British losses in aircraft totaled about 300; those of the Axis, about 332. Crusader was a British victory, but the price paid, especially in tank losses, was heavy. It was apparent that British equipment and standards of tactical training, although more than a match for Italian troops, were still below those of the German Africa Corps.

Meanwhile, outside the Mediterranean theater, great events had taken place. On Dec. 7, 1941, the Japanese delivered a crippling air assault against the United States naval base of Pearl Harbor. This brought the United States into the war against Germany and Italy. With Britain, the Soviet Union, and the United States in alliance, eventual victory over Germany and Italy, and the new Japanese enemy, seemed certain.

Naval Operations in 1941.—As all British Commonwealth personnel and supplies for the land forces in the Mediterranean had to come by sea, except for a small proportion sent by air, it was of vital importance to keep water communications open. This was comparatively easy in the Indian Ocean and Red Sea, through which reinforcements and supplies from Australia, New Zealand, India, and, frequently, North America, arrived, although there was some anxiety for this route when Japan entered the war. The Mediterranean was, however, by far the more important area of naval warfare. There the British and Italian navies, supported by seaborne and shore-based aircraft, strove to safeguard their own communications and cut those of their opponents.

After the attack on Taranto by British air-

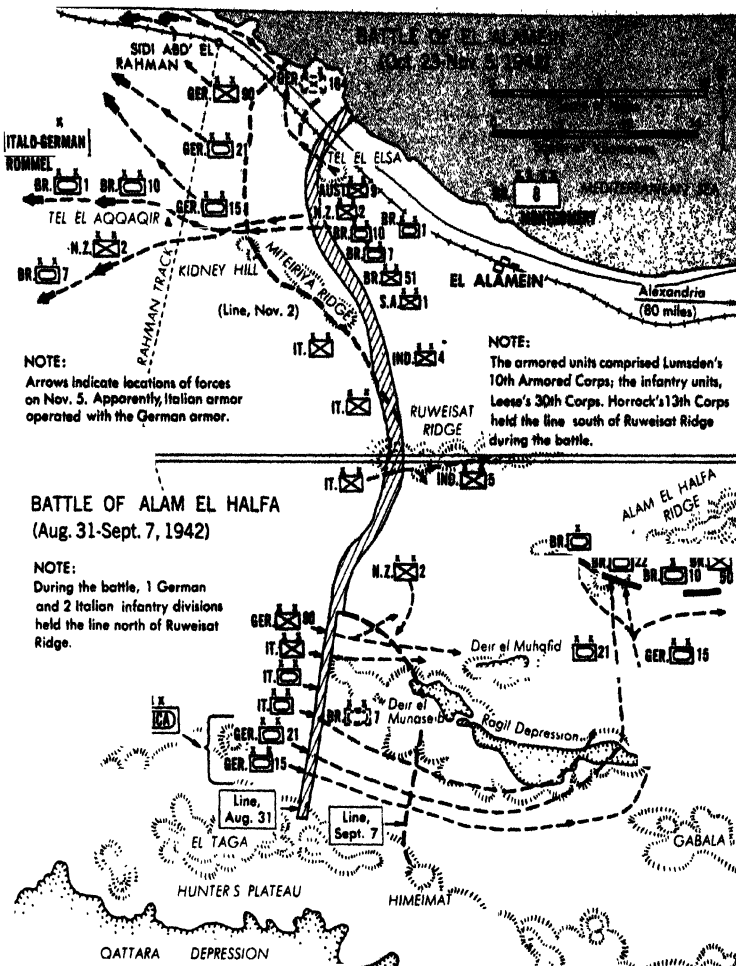

craft in November 1940, the chief events of naval interest were the bombardment of Genoa (Feb. 9, 1941), the British naval success at Cape Matapan (Tainaron; March 28), and numerous actions and convoy work connected with the British expedition to Greece and the subsequent occupation of Crete (April-May). An Italian motorboat attack on the harbor of Valletta, on July 25-26, was completely defeated, but the British subsequently lost the warships *Ark Royal* (November 13) and *Barham* (November 25), and attacks by Italian "human torpedoes" on the harbor of Alexandria resulted in severe damage to the *Queen Elizabeth* and the *Valiant* (December 19).

Throughout 1941, Malta was a target for Axis shore-based aircraft. The many attempts to reinforce, reequip, and fly fighter aircraft to Malta from aircraft carriers cost the British many lives, the carrier *Ark Royal* and numerous other warships, and many merchant ships, valuable cargoes, and aircraft. But Malta held out and was of incalculable value during the Allied invasions of Sicily and the Italian mainland in 1943.

British Defeats in North Africa and the Turn of the Tide: May-November 1942.—At the beginning of May 1942, the British war cabinet was pressing for an early offensive in the Western Desert, and General Auchinleck made the necessary plans. In this he was anticipated by General Rommel, as on May 27, Axis forces attacked the El Gazala-Bir Hacheim position in strength. For several days the battle hung in the balance, but on June 5 the Axis began to get the better of the fighting, and there followed a series of disaster for the British. By June 12, the so-called "Cauldron" Battle had been lost; the Free French troops, after heroic resistance at Bir Hacheim, had been withdrawn; and British armor had suffered a major defeat. The decision to withdraw from the El Gazala line was made on June 14. On June 21, the mainly South African garrison of Tobruk was forced to surrender. Four days later, General Auchinleck assumed direct control of the Eighth Army, which took up a defensive position running from north to south, with its right on the sea near El Alamein and its left on the Qattara Depression. Attempts by Rommel to break through this position between July 1 and July 5 failed, and on July 10, General Auchinleck started a series of counterattacks with limited objectives that lasted until July 26. By this time both sides were exhausted, the British through a series of defeats and heavy losses, and the Axis mainly because of logistic difficulties but also because of considerable casualties. Once again German armor had demonstrated its superiority in material qualities, training, and tactical handling. It was, however, the last Axis success in Africa.

Between August 4 and August 10, Prime Minister Churchill visited Cairo and held a series of meetings, in which he was joined by Field Marshal Jan Christian Smuts, prime minister of South Africa; Gen. (later Field Marshal) Sir Alan F. Brooke (later 1st Viscount Alanbrooke), chief of the Imperial General Staff; and General Wavell, who was now commander in chief in India. As a result, major changes were made. On August 13, Lt. Gen. (later Field Marshal) Bernard Law Montgomery (later 1st Viscount Montgomery of Alamein), assumed command of the Eighth Army, and two days later Gen. (later Field Marshal) Sir Harold Alexander (later 1st Earl Alexander of Tunis) succeeded General

Map 31. BATTLES OF ALAM EL HALFA AND EL ALAMEIN (Aug. 31-Nov. 5, 1942). Appreciating his poor strategic position at El Alamein, Field Marshal Erwin Rommel decided to attack to reach a decision. The pattern of warfare in northeastern Africa had developed into one of envelopment by armored forces. Lt. Gen. Bernard Law Montgomery, knowing this and lacking complete confidence in the operational abilities of his new armored units, had them dig into defensive positions on Alam el Halfa Ridge to meet the inevitable German envelopment. Rommel, as expected, burst through the weak southern part of Montgomery's line and turned northward to complete his envelopment. At the ridge he met the dug-in British tanks; frustrated and short of fuel, he withdrew his forces. Montgomery did not pursue the enemy, but prepared for a deliberate offensive. This came in the north several months later. It was not an easy operation. The German and Italian armor had shifted northward to meet the blow, and a slugging match ensued. Eventually, through sheer superior power, Montgomery's forces broke through and forced a general Italo-German retreat. Logistical and other considerations delayed Montgomery's pursuit, and Rommel reached Tunisia in time to engage in the final Allied-Axis operations for the control of Tunisia.

Auchinleck as commander in chief in the Middle East. A number of lesser appointments also changed hands about this time.

The directive given by Churchill to General Alexander stated that his main duty was to destroy as early as possible the German-Italian army commanded by the recently promoted Field Marshal Rommel. Immediately after General Montgomery took command of the Eighth Army, he began the task of reorganizing and redispersing his troops. He also made known that there would be no further retreat, and that, if attacked, the army would fight where it stood, on what was known as the Alam el Halfa position. The British had not long to wait, for by August 25 it was apparent that Rommel was about to assume the offensive. Available to him for this operation were 4 German and 6 Italian divisions, of which 2 German and 2 Italian divisions were armored. To meet this force, Montgomery had 7 divisions, of which 2 were armored.

The attack began against the southern flank of the Alam el Halfa position in the early hours of August 31. Fighting continued throughout that day and the next, but the British held fast. By the evening of September 2 the Axis armor was short of fuel, and, with little prospects of success, Rommel began to withdraw his forces. He was in full retreat by the following day. The retreating Axis columns were heavily attacked

from the air, but Montgomery did not press the pursuit with his ground troops. For this he was criticized in some quarters, but he suspected a trap to lure his armor onto the powerful and numerous Axis antitank guns and was doubtful if his troops were yet a match for the Germans in fluid operations. By September 7, the battle was over.

After Alam el Halfa, Churchill pressed strongly for an early offensive, but Montgomery was adamant that this would be unwise. He informed the prime minister that an early offensive would fail, but that he guaranteed the success of one late in October. Meanwhile, the greatest energy was displayed throughout the Eighth Army to accustom the troops to new equipment (which was now being delivered in increasing quantities), to reorganize the forces, and above all to improve the standard of tactical training. By October 20, all was ready for the Battle of El Alamein. Montgomery disposed of the equivalent of 11 divisions (3 armored), organized in three corps. To meet this force Rommel had 13 divisions, 4 of which were German. Of his 4 armored divisions, 2 were German and 2 Italian. The British attack opened on the night of Oct. 23-24 with a massive artillery bombardment. Bitter fighting continued for several days, during which both sides lost heavily and fortunes fluctuated. After a short pause to regroup, Montgomery re-

newed the attack on November 2. By November 3, the battle had turned in favor of the British, and Rommel began to withdraw, pursued by the British 30th Corps (the 1st and 7th armored divisions and the New Zealand 2d Division).

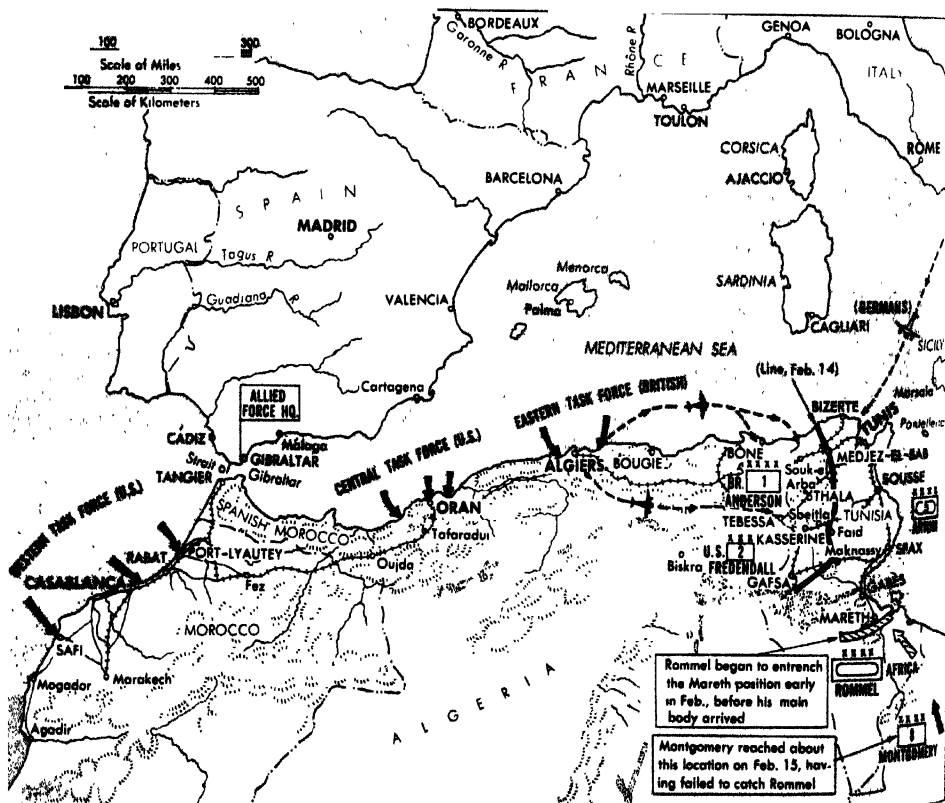

Anglo-American Invasion of French North Africa: November 1942–May 1943.—The Battle of El Alamein was not only the beginning of a series of unbroken victories; it was also the start of a new phase in North Africa. Henceforth the campaign in the Mediterranean was to be a joint Anglo-American undertaking. For some months the American and British staffs had been working on a plan for the occupation of French North Africa, with a view to the elimination of all Axis forces from Africa and as a preliminary to the invasion of Italy. At the end of August 1942, an Allied headquarters had been established in London for Operation Torch, the code name for the enterprise. The over-all command of sea, land, and air forces was vested in the American Lt. Gen. (later General of the Army) Dwight D. Eisenhower. The land forces consisted of the British First Army under Lt. Gen. (later Gen.) Sir Kenneth K. N. Anderson and the United States 2d Corps under Maj. Gen. (later Lt. Gen.) Lloyd R. Fredendall. Initially these formations

were very weak, the First Army being little more than a weak corps, but as the campaign proceeded they greatly increased in strength.

The first landings took place on November 8 and by the morning of November 11, Algiers (Alger), Oran, and Casablanca were in Allied hands. The French troops, acting under orders from the Vichy government, offered some resistance, but nowhere was this wholehearted, and in many places it was merely token. On November 11, all hostilities between the Allies and the French in Algeria and Morocco ceased, and on the following day, Adm. Jean François Darlan, now recognized as the French high commissioner in North Africa, handed over the French territories to the Allies and appealed to the French Fleet at Toulon to cross over to North Africa. Events moved quickly. By the end of November, the Germans had occupied the whole of France, and most of the French warships at Toulon had been scuttled by their crews. Meanwhile, the Axis forces in Tunisia were being heavily reinforced by air and through the ports of Bizerte and Tunis.

On December 11, the Allied advance in Tunisia was halted by Axis counterattacks in the area of Medjez-el-Bab. Then, on December 24,

Map 32. ALLIED INVASION OF FRENCH NORTH AFRICA (Nov. 8, 1942–Feb. 14, 1943). On Nov. 8, 1942, as Lt. Gen. Bernard Law Montgomery took up the pursuit of Field Marshal Erwin Rommel after the latter's defeat at El Alamein, Anglo-American forces landed in French North Africa, as shown on the map. The plan was to drive quickly to Tunis, cut off Rommel, and clear Africa of Axis forces. British amphibious and airborne troops sped to Tunisia to seize and hold advanced positions until the main Allied force arrived. The Germans began to rush reinforcements to Tunisia by air and by sea to thwart the Allied effort, and a race between the German buildup and the Allied advance began. By Feb. 14, 1943, the Germans had accumulated sufficient strength to stop the Allies on the line shown and to hold the gate open for Rommel.

In July 1942, the British Eighth Army was in position near El Alamein. Here Scots Guards are shown going into action in one of a series of counterattacks. After British strength had been built up by Lt. Gen. Bernard Law Montgomery, the Germans were decisively defeated in the battles of Alam el Halfa (August 31–September 2) and El Alamein (October 23–November 5).

Wide World

the already difficult political situation between the Allies and the French authorities was complicated by the assassination of Admiral Darlan. By this time the Allies were supported by numerous French troops under Gen. Henri Giraud; these, although at first inadequately armed, greatly improved in quality toward the latter stages of the campaign.

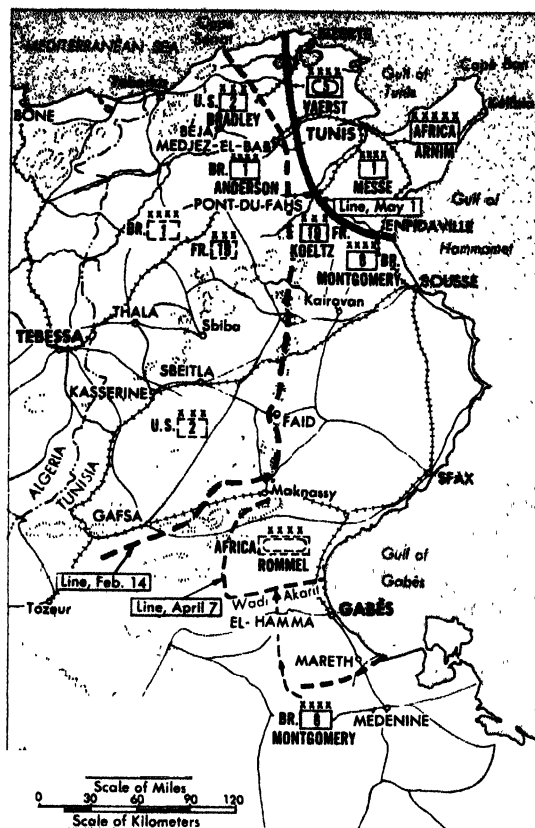

During January 1943, both sides confined themselves to local operations and attempted to build up sufficient strength for a decisive offensive. Then, on February 14, Axis forces launched a powerful attack against the United States 2d Corps, which, heavily outnumbered, was driven back about 50 miles between Faïd Pass in the north and Gafsa in the south. Kasserine and Sbeitla were captured, and the enemy, advancing up the Kasserine Pass, threatened the important centers of Tebessa and Thala. This advance was serious, for it endangered some of the Allied forward airfields. By February 23, the advance of the Axis forces had been halted, however, and between February 26 and March 3 they were driven back to approximately their original positions. It had been a difficult period for the Allies, but General Eisenhower had demonstrated that he was a field commander of the first order.

Meanwhile, the British Eighth Army, after its victory at El Alamein, had made rapid progress. Tobruk was captured on Nov. 13, 1942; Benghazi, on November 20; Tripoli on Jan. 23, 1943; Mareth, on March 20; and Gabès, on March 29. On April 6, Wadi Akarit was attacked, and on the following day troops of the Eighth Army made contact with the Allies advancing in Tunisia. In mid-February, General Alexander had flown from Egypt to join General Eisenhower as his deputy. In that capacity he was charged with coordinating the action of the First and Eighth armies and of all Allied ground troops operating in North Africa—American, British, and French. Mid-April saw an extensive regrouping of Allied forces, including the transfer of several of the Eighth Army's best troops to the First Army, as it was considered that better and quicker results would be achieved if the final blow was struck in the north rather than in the south, where the country was more difficult and unsuitable for armor.

On May 1, the 120-mile Allied front ran roughly from Enfidaville northwestward to Pont-du-Fahs and then northward to the coast about 18 miles west of Bizerte. The British Eighth Army was on the right, French units on the right center, the British First Army on the left center, and the United States 2d Corps on the left in the coastal strip. The main attack, by the First Army and the 2d Corps, began on May 4, the British drive being directed on Tunis and the American drive on Bizerte. The assaulting troops were supported by a powerful force of aircraft, and the attack was preceded by a heavy artillery bombardment. Although the Axis troops fought with great determination, by May 6 the defense had cracked, and on the following day American and British troops entered Bizerte and Tunis, respectively. Confused fighting occurred from May 7 to May 12, but the British succeeded in clearing the Cape Bon Peninsula, where it had been thought that the Axis troops might make a last stand.

On May 13, all Axis forces laid down their arms in surrender. About 240,000 prisoners were taken, including 125,000 Germans. Col. Gen. Dietloff Jürgen von Arnim, the German commander in Tunis, was among those captured. Field Marshal Rommel escaped.

With the surrender of Axis forces in Tunis, no Germans or Italians remained in arms in Africa. From the time that Italy entered the war in June 1940, the number of Axis soldiers killed or captured in Africa totaled about 950,000. Approximately 2,400,000 gross tons of Axis shipping were sunk, and 8,000 aircraft were destroyed. In addition, 6,200 guns, 2,500 tanks, and 70,000 trucks were captured or destroyed. Allied shipping losses and British losses in army equipment in 1942 were also heavy and serious. Casualties in personnel, however, were only a fraction of those suffered by the Axis. Apart from the heavy Axis losses, the latter stages of the campaign in North Africa brought the Allies many advantages. Very soon the victory was to result in Italy's defection from the Axis partnership, and it paved the way for the reentry of the Allies to the European mainland. Moreover, the Tunisian campaign showed that American and British sailors, soldiers, and airmen could fight efficiently as one team, under one commander, against the common enemy.

Map 33. EXPULSION OF THE AXIS POWERS FROM AFRICA (Feb. 14-May 13, 1943). On Feb. 14, 1943, the Axis forces attacked the United States 2d Corps front in Tunisia, driving almost to the key towns of Tebessa and Thala. There the resistance of the Allies stiffened, and their subsequent counterattacks forced the Italo-German troops back to about their original positions. The British Eighth Army pushed Rommel northward and joined the Allied line on April 7. By May 1, the Axis forces had been penned into the northeastern tip of Tunisia. Under constant pressure, 240,000 troops (about half of them Germans) surrendered on May 13. Field Marshal Erwin Rommel himself escaped. All of Africa was now clear of Axis forces, and Sicily and the Italian mainland lay vulnerable to Allied attack.

CAMPAIGNS IN ITALY

Conquest of Sicily: June-August 1943.—Some weeks before the end of hostilities in North Africa detailed planning had begun for the capture of Sicily, to be followed by the invasion of the Italian mainland. On June 11, 1943, the island of Pantelleria, with its Italian garrison of 15,000 men, surrendered to the Allies, and the smaller islands of Lampedusa and Linosa surrendered on June 12 and 13, respectively.

The Allied forces in the Mediterranean were ready for the invasion of Sicily by early July. Under the supreme command of General Eisenhower, the land forces consisted of the Fifteenth Army Group under the direction of General Alexander, comprising the United States Seventh Army, commanded by Lt. Gen. (later Gen.) George S. Patton, Jr., and the British Eighth Army under General Montgomery. Axis forces in Sicily numbered about 75,000 Germans and 275,000 Italians. The German forces included the 15th Panzer Division with about 60 tanks and

the Hermann Goering Division with about 100 tanks. The Italians had four divisions and 100 light tanks.

The Allied troops taking part in the assault came from widespread areas: the American 1st and 3d divisions and the British 51st (Highland) Division from North African ports; the American 45th Division, from the United States; the Canadian 1st Division, from the United Kingdom; and the British 5th and 50th divisions and the 231st Infantry Brigade, from the Middle East. The Allied invasion fleet, comprising 3,000 ships and craft carrying about 140,000 men and covered by powerful naval and air forces, was approaching Sicily on the afternoon of July 9, when a severe storm blew up that threatened the landings with disaster. On the next morning, however, the assault took place as planned, the British Eighth Army landing in the southeastern corner of the island, and the United States Seventh Army on the south coast. The assault by sea was preceded by American airborne landings near Gela and by British landings near Syracuse (Siracusa). The first Allied airborne operations on a big scale, they were only partially successful because of the stormy weather. Many men and gliders landed at some distance from their targets, some of them falling in the sea. But the assault as a whole was successful, and Syracuse was captured that day.

By July 22, British Commonwealth forces had advanced northward to the foothills of Mount Etna, while American troops had overrun the western part of the island, capturing Agrigento and Palermo. Only the northeast held out. By August 15, Randazzo and Taormina had been captured, and by August 17 all Axis resistance in Sicily had ceased. Allied casualties included 6,896 Americans and 12,843 British. Axis killed wounded, and prisoners numbered about 164,000 of whom approximately 32,000 were Germans. The Allies captured or destroyed about 1,500 aircraft, 78 armored fighting vehicles, 287 guns, and 3,500 motor vehicles.

While the fighting in Sicily was in progress, important political developments had been taking place. On July 25, Mussolini was forced to resign, and Marshal Pietro Badoglio became premier of Italy, while King Victor Emmanuel III assumed command of the Italian armed forces. These events were followed by secret feelers, put out by the Allies through neutral diplomatic circles, to induce Italy to cease hostilities and if possible declare war on Germany. On September 3, a military armistice between the Allies and the Italian government was signed secretly at Syracuse. It was announced publicly by General Eisenhower on September 8.

Invasion of the Italian Mainland: September-October 1943.—Immediately after the fighting in Sicily ended, planning began for the invasion of the Italian mainland. The general plan called for the British Eighth Army under General Montgomery to cross the Strait of Messina from Sicily onto the toe of Italy and advance northward as quickly as possible. About a week later the American Fifth Army under Lt. Gen. (later Gen.) Mark W. Clark was to land in strength on the west coast at Salerno, 30 miles southeast of Naples (Napoli) and 180 miles north of Montgomery's landing place, with the objects of joining its forces with the Eighth Army, cutting off substantial German forces in southern Italy, and capturing the port of Naples at an early date.

Sicilians cheer victorious American troops as they ride through the streets of Monreale on their way to Palermo, which surrendered on July 22, 1943.

Robert Capa-Magnum

Events moved quickly. On September 3, the Eighth Army, with massive sea and air support, crossed the Strait of Messina at Reggio di Calabria and advanced rapidly northward against light opposition. Eisenhower's announcement five days later of the capitulation of Italy regularized the withdrawal of the country from the war (which for all practical purposes had already taken place), but it did not as yet bring Italy into the conflict as a cobelligerent against Germany. The port and naval base of Taranto was occupied by British airborne forces on September 9. Two days later, the main part of the Italian Navy steamed into Valletta under escort, and Admiral Cunningham was able to signal the British Admiralty: "Be pleased to inform Their Lordships that the Italian battle fleet now lies at anchor under the guns of the fortress of Malta." During their voyage to Malta the Italian warships were heavily attacked by German aircraft. The flagship *Roma* was hit, caught fire, and blew up. Most of her crew, including the commander in chief, were lost.

The Fifth Army began landing at Salerno on September 9. For some days the Allied intelligence staff had known that Germans had replaced Italian troops in the Salerno area. There was some opposition on the beaches, but on the whole the landings went smoothly and without very heavy fighting. Although the Germans made furious counterattacks on the beachhead on September 13, the crisis was over by September 16, and on that day troops of the Fifth and Eighth armies linked forces. Troops of the Fifth Army occupied Naples on October 1, by which time the British 1st Airborne Division, which had landed at Taranto on September 9, had captured the important airfield at Foggia.

By October 12, the Allies had established a reasonably solid front across the Italian Peninsula, from Foggia on the Adriatic coast to just north of Naples on the west coast—a distance of about 120 miles. The Eighth Army was on the right, and the Fifth Army on the left. Success had been swift: within six weeks the Allies had captured and occupied a substantial part of Italy. There were, however, many hard battles still to be fought. Meanwhile, on September 19, the Italian island of Sardinia had fallen to the Allies, and on October 4 the French island of Corsica was taken.

Strategic Considerations.—The over-all policy, agreed to by the Allies for conducting the war, was that the main effort should be directed first

to the defeat of Germany, after which all available forces would be concentrated against Japan. There was, however, some difference of opinion between the American and British governments and their military advisers as to the best strategy for northwestern and southern Europe. The British at first favored exploiting the Mediterranean theater on the grounds that the Allies were already established there, that no further assault landings would be necessary, and that an attack on Germany through Italy and the Balkans would prevent the spread of communism in central Europe. The Americans held that a cross-Channel attack based on the United Kingdom was the easiest way of getting quickly to the heart of Germany and greatly simplified the logistic problem. They pointed out that while British Commonwealth forces received many of their reinforcements and much of their equipment and supplies through the Red Sea and the Suez Canal, the route from North America to the Mediterranean was longer, more dangerous, and logistically less convenient than that to the United Kingdom and the mainland of northwestern Europe. The American staff also drew attention to the formidable mountain ranges, very suitable

Imperial War Museum, London

for defense, which would have to be negotiated in an advance on Germany from southern Europe.

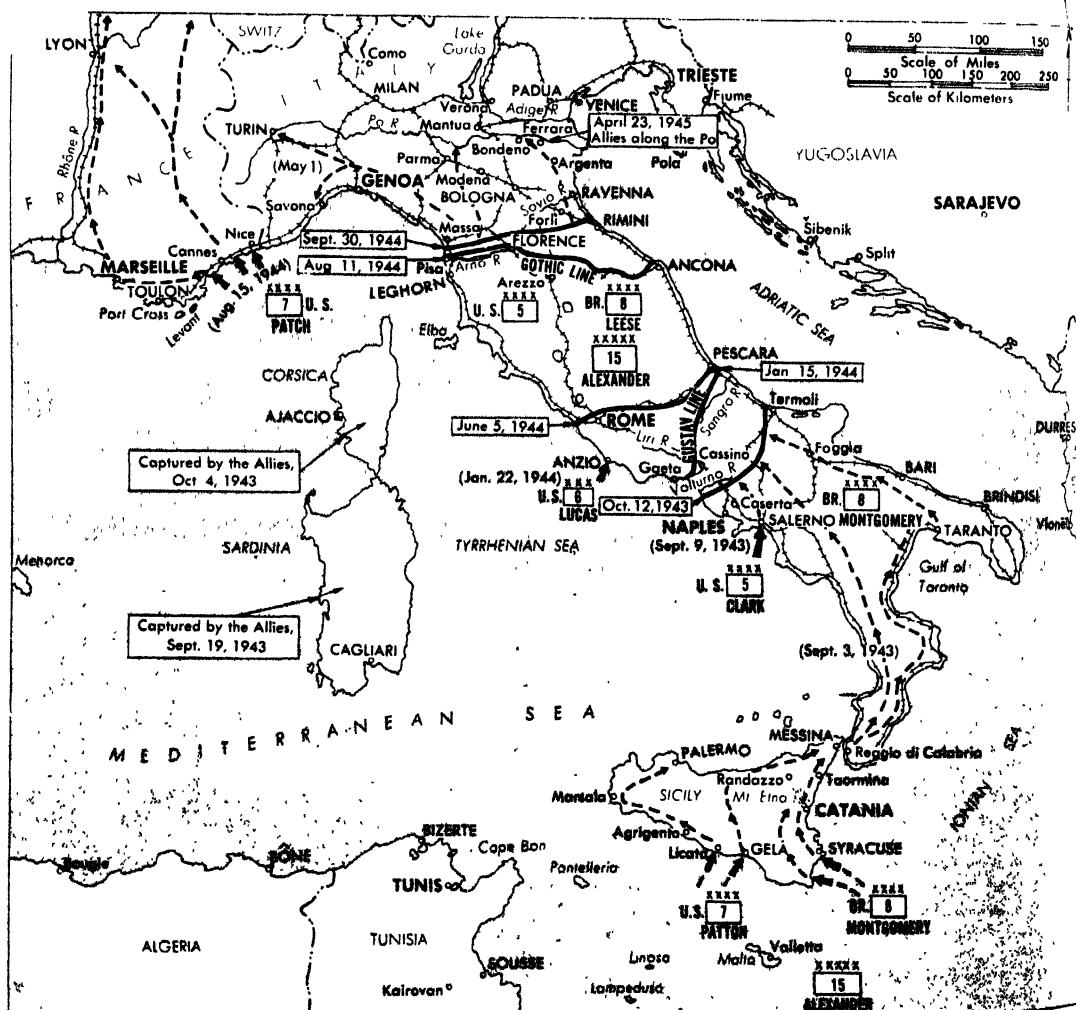

By the late summer of 1943 the American view had prevailed. Planning for Operation Overlord was in progress, and in consequence the Mediterranean theater tended to decrease in importance, although it was still to play a major part in Allied strategy. As soon as the Sicilian campaign was over, the Allies began to transfer 7 divisions (4 Americans and 3 British) from the Mediterranean to Britain in preparation for Overlord, which it was expected would take place in the late spring of 1944.

Following the conquest of Sicily and the surrender of Italy in September 1943, another important strategic matter arose. This was the question of occupying some of the islands of the Dodecanese, off the coast of Turkey, which were

mostly garrisoned by Italians. General Eisenhower was opposed to diverting troops from Italy for this purpose, but the Middle East command under General Wilson sent detachments, carried and escorted by British warships, to Leros and some smaller islands. While the Italian garrisons were friendly, they were not prepared to fight Germans in defense of the islands. Against heavy German threats the British garrisons were withdrawn by mid-November, and the Germans reoccupied the islands. British naval losses in these abortive operations comprised 6 destroyers and 2 submarines sunk by mines or German aircraft, and 4 cruisers and 4 destroyers damaged.

Operations on the Italian Mainland: October 1943–August 1944.—On Oct. 13, 1943, Italy declared war on Germany, and thereafter Italian partisan forces played an increasing role in the

Map 34. CONQUEST OF SICILY AND THE ITALIAN MAINLAND (July 9, 1943–May 2, 1945). After the capture of Tunisia, the Allies invaded Sicily as a steppingstone to Italy proper. Airborne landings were made late on July 9, and seaborne landings were made on July 10 as shown. By August 17, the island had been overrun, and a major portion of its garrison had been captured. Italy signed an armistice with the Allies in early September. At the same time, the American Fifth and British Eighth armies invaded the Italian mainland and advanced to a line above Naples. The two armies were to spend the rest of the war in the most depressing type of warfare—the attack of successive defensive positions across rivers and mountains. In the spring of 1945, the Allies finally broke through into the northern Italian plain. Thereafter the disintegration of the German forces was rapid; on April 29, they surrendered (effective May 2). The operations in Italy were costly to both sides, but they kept one third of Adolf Hitler's forces in western Europe pinned down and away from the decisive fronts.

war against their former Axis partner. By early November, the Allied land forces in Italy consisted of the American 3d, 34th, and 45th Infantry, 82d Airborne, and 1st Armored divisions and the British 46th, 56th Infantry, and 7th Armored divisions, of the Fifth Army; and the 5th, 78th, 1st Canadian, 8th Indian, 2d New Zealand, and 1st Airborne divisions, of the Eighth Army. About this time plans were made to transfer the French Corps under Gen. (later Marshal) Alphonse Pierre Juin from North Africa to Italy. Later the troops in Italy were to be joined by the Polish Corps under Gen. Władysław Anders and by other American, British, and Canadian formations.

The winter of 1943–1944 was a period of hard fighting which brought the Allies up to the German Gustav Line. The Fifth Army crossed the Volturno River on October 13. On November 8, General Alexander issued a directive for offensives by the Fifth and Eighth armies. The Eighth Army began its offensive on the Sangro River on November 20, and the Fifth Army attacked in the Liri Valley on December 1. In both cases the advance was limited, as neither army was strong enough to exploit its success.

In January 1944, there were important changes in command. General Eisenhower left the Mediterranean theater to direct Overlord and become supreme commander of the Allied Expeditionary Force in northwestern Europe. He was succeeded as supreme commander in the central Mediterranean by General Wilson. General Alexander remained as commander in chief in Italy. General Montgomery, who returned to the United Kingdom to command the Twenty-first Army Group, was succeeded by Lt. Gen. Sir Oliver Leese in command of the Eighth Army.

As early as October 1943, plans for an amphibious Allied landing near Anzio had been considered. As finally approved, the landing was to be made by the United States 6th Corps under Maj. Gen. John P. Lucas, comprising 1 United States infantry division, a United States armored element, a battalion of Rangers, a parachute regimental combat team, and 1 British infantry division, a British armored element, and 2 Commando units. The object of the landing was to cut the communications of the German 14th Corps, assist the main Allied armies to advance to the north, and capture Rome (Roma). The landing took place on Jan. 22, 1944. The leading troops advanced about 10 miles but were then halted by stubborn resistance. The German commander, Field Marshal Albert Kesselring, concentrated 10 German divisions against the 4 which, with further reinforcements, the Allies had established on the beachhead. While the Anzio beachhead held firm, little progress was made by the Allies on any front, and it was nearly five months before Rome was captured.

At the end of March 1944, the Allied position facing the Gustav Line extended for 100 miles westward across Italy, from the Sangro River to Cassino and thence to the Tyrrhenian Sea near the mouth of the Garigliano (lower Liri) River. The Anzio beachhead was firmly held. The key position in the Gustav Line was Monte Cassino with its famous Benedictine abbey on the summit. This position was attacked first by the United States 2d Corps (the 34th and 36th divisions) in January; then by the New Zealand 2d Corps (the New Zealand 2d, Indian 4th, and British 78th divisions and a combat group of the United States

1st Armored Division) in February; and for a third time, again by the New Zealand 2d and Indian 4th divisions, in March. All three attacks failed despite the fact that the last two were preceded by massive bombardments by heavy bomber aircraft as well as by artillery. The Allies spent the month of April and first half of May regrouping and planning for a further assault on the Gustav Line at Cassino, preparatory to an advance on Rome. By this time the strategy in the Mediterranean had definitely become subordinate to northwestern Europe, where the cross-Channel assault was planned for early June. General Alexander defined the task of the forces in Italy as follows: "To force the enemy to commit a maximum number of divisions in Italy at the time the Cross-Channel invasion is launched."

The fourth and last assault on the Cassino position was carried out by the Polish Corps, with the British 2d Corps on its left ready to advance up Highway 6 in the Liri Valley and open the road to Rome. Farther to the left the Fifth Army (which included the French Corps) was to advance on Rome, using Highway 7 as its main axis. The offensive was supported by 1,000 guns with the Eighth Army and 600 with the Fifth Army and by more than 3,000 aircraft. The battle began on May 11, but it was not until the morning of May 18 that the Poles were able to occupy the abbey of Monte Cassino. The whole Allied battlefront westward from Cassino then surged forward, and events moved rapidly. On May 23, the Allied forces in the Anzio beachhead took the offensive and joined the troops of the Fifth Army advancing from the south. By this time the Germans had decided to give up the Gustav Line, and their next position, the Hitler Line, was already pierced. On June 4, American troops of the Fifth Army entered Rome, which the Germans had declared to be an open city. The bridges were left intact, and the city was saved many of the ravages of 20th century warfare. Two days later, on June 6, the forces in Italy learned of the successful Allied landings on the Normandy coast.

After the capture of Rome the Allies pressed northward on what was in reality two fronts divided by the Apennines and with only slight ground contact over the mountain barrier. One portion of the Eighth Army was to the east of the Apennines; the Fifth Army and the rest of the Eighth Army, to the west. The full exploitation of success was prevented by the withdrawal of more troops from Italy to help the Allies in northwestern Europe by means of landings in southern France. Pescara on the Adriatic was captured on June 11, Arezzo on July 16, Ancona on July 18, Leghorn (Livorno) on July 19, and Florence (Firenze) on August 11. The Allies now faced the German Gothic Line, which ran from the Adriatic to the north of Ancona, north of Arezzo and Florence, to the west coast north of Leghorn, or about 150 miles.

Allied Landings in Southern France: August–September 1944.—At the Teheran Conference (Nov. 28–Dec. 1, 1943) it had been agreed that the landings in northwestern Europe would be followed by further landings in the south of France. After the fall of Rome preparations began to implement this decision at the expense of General Alexander's forces in Italy. It was now proposed to withdraw 7 good divisions from the Fifth Army: 3 American (the 3d, 36th, and 45th) and 4 French. Known at first as Anvil, the operation was later code named Dragoon. Planning and

execution were entrusted to the headquarters of the United States Seventh Army under Maj. Gen. (later Lt. Gen.) Alexander M. Patch. The troops consisted of the United States 6th Corps, commanded by Maj. Gen. (later Lt. Gen.) Lucian K. Truscott and composed of 3 United States divisions; and the French 2d Corps, composed of divisions formerly in Italy, under Gen. Jean de Lattre de Tassigny.

Early on the morning of Aug. 15, 1944, a special service force of American and Canadian units seized the offshore islands of Levant and Port-Cros, while French Commando troops landed on the French Riviera mainland immediately to the north. Farther inland and 22 miles west of Cannes, the 1st Airborne Task Force, consisting of American and British airborne units, was dropped. These preliminary operations were quickly followed by seaborne landings of major formations of the Seventh Army between Nice and Toulon. German resistance was not sustained, but it was tenacious in places, especially at Toulon and Marseille. By August 27, the French had captured Toulon, and on the following day, Marseille. After liberating southern France the Allied force moved via the Rhone and Doubs valleys to the Belfort gap. It then joined with the Allied armies in northwestern Europe, came under General Eisenhower's command, and ceased to be within the Mediterranean theater of operations.

For a more detailed account of operations in southern France in 1944, see section 5. *Recovery of France and Advance into Germany.*

Campaign in Italy: August 1944–May 1945.—

Despite the weakening of his forces, General Alexander made early plans for an assault on the Gothic Line. This involved the transfer of troops from the western or left flank to the right flank in preparation for an attack on the enemy's left. The offensive was opened by the Eighth Army on Aug. 25, 1944, and by August 31 the German front had been pierced on a line 20 miles long to a depth of 4 miles. On the left the Fifth Army, which included some British Commonwealth formations, also attacked vigorously, and by September 13 had broken the enemy front north of Florence. Rimini fell to the Allies on September 21, and by September 28 the Gothic Line had been forced. This phase of the Italian campaign was an exceptionally fine operation by the Allies, carried out despite dwindling numbers in difficult mountain country well suited to defense. The price, however, was a heavy one—approximately 50,000 casualties. When the offensive was halted at the end of September, the line ran across Italy from east to west for about 150 miles, from north of Rimini to north of Florence and Pisa.

There followed a lull of about six weeks, but elsewhere in the Mediterranean theater an important development took place. In the late summer of 1944 it became apparent that the Germans were preparing to withdraw from Greece. The country was in ruins, however, and clearly the first requirement was an Allied force to maintain law and order, prevent the country from falling under Communist domination, carry out relief work, and generally reestablish stable conditions. Operation Manna, the code name for the relief force, was ready by mid-September, its commander being the British Lt. Gen. (later Sir) Ronald M. Scobie. Except for some Greek units, which had been operating under Allied command in Italy, the force was mostly British, including initially the 2d Parachute Brigade, 23d Armored Brigade (in an

infantry role), and administrative units. The land forces were to be supported by the 15th Cruiser Squadron, United States transport aircraft, and four British and three Greek air squadrons.

On September 26, a conference took place at Allied headquarters at Caserta, Italy, which was attended by representatives of Premier George Papandreou's Greek government in exile and leaders of the two principal Greek partisan groups, the National Liberation Front (EAM) and the Greek People's Army of Liberation (ELAS). The latter both agreed to operate under General Scobie's orders. On October 3, British Commando and airborne troops landed in southern Greece and on the next day occupied Patras (Patrai). Additional airborne forces landed at Megara Airfield, outside Athens, on October 13, and on the following day moved into the capital on the heels of the retreating Germans. Naval forces immediately entered Piraeus (Peiraeus), bringing General Scobie and the rest of his force, followed two days later by the Greek government.

By November 8, the last formed bodies of German troops had left Greece, but their departure did not bring peace. The rival partisan groups—the left-wing EAM and ELAS and the anti-Communist EDES (National Greek Democratic League)—were openly hostile to the Greek government, and in addition quarreled and fought among themselves. The partisans' promise to take orders from General Scobie was soon broken. Toward the end of November, Scobie's command was reinforced by the Indian 4th Division. The last days of November and early December saw a bid by ELAS to take over Athens, and clashes between British troops and ELAS occurred in the city on December 5. In the face of increasing partisan opposition some of the smaller British detachments had to be withdrawn, a few suffering casualties in the process.

With the situation worsening, the Greek government and the Allies turned to Archbishop Damaskinos as the leading figure in Greece and the man with the greatest influence over all parties. As a result of a meeting held on December 26–27, attended by the archbishop, Prime Minister Churchill, and other political and military leaders, King George II of Greece postponed his return to the country, the archbishop became regent, and Papandreou was replaced as premier by Gen. Nicholas Plastiras. In the meantime, General Scobie had been further reinforced by the British 4th Division, which was intercepted in mid-December, while on route from Italy to Egypt. Its arrival turned the scale, and by Jan. 5, 1945, Athens and Piraeus had been cleared of dissentient forces.

On February 12, representatives of the Greek government and the Central Committee of EAM-ELAS signed at Varkiza an agreement, the terms of which included the disarming and demobilization of all revolutionary forces (who were to release their hostages), a general amnesty, and the formation of a national army. Following the Varkiza agreement, British forces had little difficulty in occupying all of Greece. The worst was over and the troubles of the Greeks gave way to more urgent matters.

Meanwhile, in Italy on Nov. 3, 1944, Lt. Gen. (later Gen.) Sir Richard L. McCroery succeeded General Leese in command of the Eighth Army. During the late fall and winter the battlefield remained generally inactive, but the Allies made some progress on their right along the Adriatic

coast. Forlì was captured on November 10, and Ravenna on December 5. Operations were greatly hampered by unusually heavy rainfall during the last three months of the year. On the night of October 1, for example, approximately 8.5 inches of rain fell in the Po Valley in 10 hours, reducing the countryside to a quagmire.

On December 12, General Wilson left the Mediterranean theater to become head of the British Combined Services Mission in Washington. His place as supreme Allied commander in the Mediterranean was taken by the recently promoted Field Marshal Alexander. General Clark became commander of the Allied armies in Italy, which now reverted to the title of Fifteenth Army Group, and General Truscott took command of the Fifth Army. Between Dec. 28, 1944, and Jan. 2, 1945, the Germans made a powerful counter-attack against the Allied left in the Serchio Valley north of Pisa. It fell mainly on the Indian 8th Division, which stood firm and repulsed the attack with heavy losses to the Germans.

In mid-March, Allied intelligence staffs estimated that about a third of the German strength in the west was employed in Italy, and this was judged to be an important factor in the success of Overlord. Special measures were taken to make this known to the Allied troops in Italy, and it proved a useful antidote to the disappointment caused by the earlier withdrawal of troops, which had prevented the Allies from completing the conquest of northern Italy. By the early spring, Italian troops were playing a considerable role in operations against their former German partners. Their activities were mostly of the guerrilla type, but they also had some field units in action.

On April 9, German strength in Italy was the equivalent of 26 divisions, including 1 panzer and 1 light (motorized) division. On this day the Eighth Army on the right launched a major offensive, supported by heavy air and artillery bombardments, and crossed the Senio River. On the Allied left the Fifth Army also carried out a heavy attack, capturing Massa and crossing the Eugido River. On April 16, Field Marshal Alexander and General Clark made it known that the hour for the final battle for Italy had arrived. On the Adriatic side the offensive of the Eighth Army had been designed in the initial stages to give an opportunity to exploit success, either through the Argenta gap near the coast or farther west through Bologna. Argenta was the choice; on April 17 the gap was secured, and the town itself was entered the next day. Meanwhile, the Fifth Army offensive, which had begun on April 14, met with stubborn resistance in the mountains, but once the battlefield reached open country the German withdrawal became a rout.

On both fronts the retreating enemy was pursued by Allied armor and pounded by Allied aircraft. The object of the Germans was to get as many troops and as much equipment as possible north of the Po River. Bologna fell to the Fifth Army on April 21, and on April 23 leading armored elements of the Fifth and Eighth armies met south of the Po in the Ferrara-Finale nell' Emilia area, where they created havoc among German troops and transport crowding the roads to reach the river bridges. By that evening the Fifth and Eighth armies had reached the Po on a wide front. Ferrara, Bondeno, and Modena (all south of the Po) fell on April 24, and by the evening of April 25 approximately 30,000 German

prisoners were in Allied hands, and a substantial part of the German armor, artillery, and transport had been destroyed or captured. Such was the measure of the defeat of the Germans south of the Po that they were unable to offer any serious resistance on this formidable river line, which the Allies crossed without serious opposition.

Operations now entered the area of Napoleon's Italian campaigns, and familiar names appeared on the air and in written messages. On April 26, Mantua (Mantova) and Verona fell, and the Adige River was crossed. At this stage it was revealed that the area west of the Como-Milan (Milano)-Genoa (Genova) line was virtually under the control of Italian resistance troops, who had been organized by Allied liaison officers and equipped from Allied sources. Genoa was occupied by the Fifth Army on April 27. On the following day, Mussolini was murdered by partisans. By this time the Fifteenth Army Group was firmly established across the Adige, and on April 29 it began advancing northward from the river. On the same day the Fifth Army entered Milan, and the Eighth entered Padua (Padova). On April 30, the official communiqué stated: "Troops of the Fifteenth Army Group have so smashed German Armies in Italy that they have been eliminated as a military force." About 120,000 Germans had been taken prisoner since the offensive started.

On the last day of April, purely military operations began to give way to other considerations. It was important that northeastern Italy should be occupied as quickly as possible by American and British troops. Large numbers of German soldiers, many of them detached from their units and not under regular discipline, were roaming the countryside. Many thousands of Italian partisans were to be found, not all of them under proper control. A dispute between Yugoslav partisans and Italians over the possession of Trieste seemed likely to cause a clash, and for many reasons it was desirable that Austria should be occupied as soon as possible. Although the fighting was nearly over, there was much to be done to preserve law and order and bring about a semblance of control.

Allied troops entered Savona and Turin (Torino) on May 1. On the following day, May 2, 1945, at 12 noon, hostilities in Italy came to an end as the result of an instrument of unconditional surrender signed at Caserta on April 29 by representatives of Col. Gen. Heinrich von Vietinghoff-Scheel, commander in chief of the German Southwest Army Group. Nearly 1,000,000 Germans then laid down their arms. Thus ended operations in the Mediterranean theater of war, which had begun on land on the Egyptian-Libyan frontier early on June 11, 1940, a few hours after Italy entered the war.

The purpose of the Allied campaign in Italy was to contain as many Axis troops as possible in order to ease the burden on other fronts. The extent to which this objective was accomplished can be judged by the following comparison of German and Allied strengths at various times (Italian units, which at different times formed part of the forces of both sides, are not included):

	Germans	Allies
Mid-October 1943.	19 divisions	15 divisions
Spring 1944 ¹	23 divisions	27 divisions
Summer 1944	25 divisions	20 divisions
Mid-March 1945	24 divisions	17 divisions and 9 independent brigades

¹ For a brief period only.

Allied casualties in Sicily and Italy totaled 320,955, while those of the Axis (excluding those involved in the final surrender) numbered 658,339. If to the latter figure are added the Axis casualties in North and East Africa, the total is approximately 1,610,000 killed, wounded, and prisoners.

9. War in the Southern and Southwestern Pacific¹

Japanese Dreams of Empire.—The Japanese began their efforts to establish a Greater East Asia Coprosperity Sphere (see Map 35) as early as 1931. Seizing a minor pretext, they then overran Manchuria and, in 1932, established it as a puppet state under the name of Manchukuo. Incursions into China proper followed. These were initially successful, but eventually the Japanese encountered the stubborn resistance of the Chinese, who were united under the central government of Generalissimo Chiang Kai-shek. The crisis came in

1937, when a major offensive was launched to reduce China to submission. After overrunning large areas of northern China, the Japanese found that they could not break the Chinese will to resist, and a policy of economic strangulation was adopted. By 1939 they had seized the major coastal ports and had forced the removal of the Chinese capital inland from Nanking to Hankow and then to Chungking.

In 1940, Japanese pressure on the weak Vichy government of conquered France brought important concessions in Indochina, including the right of entry of Japanese troops. Japan's formal entry into the Axis alliance with the signature of the Tripartite Pact in September 1940 provided convincing proof of her ultimate aims. A treaty was concluded with Thailand (Siam), and by the end of 1940 the Japanese were threatening the Burma Road (q.v.), the last important supply line from the outside world to China. In April 1941, Japan signed a five-year nonaggression pact with the USSR, and in July she completed the occupation of French Indochina. Her thoughts now turned to the so-called Southern Regions (the Philippines, Borneo, the Moluccas, Celebes or Sulawesi, Timor, Java, Sumatra, Malaya, Thailand, and Burma), an area extremely rich in raw materials.

Alarmed by the Japanese movements and ambitions, the United States, Great Britain, and the Netherlands, whose territories Japan coveted, joined in freezing her assets in their respective countries, thereby effectively curtailing her trade. It had long been obvious to the Japanese that the establishment of the Greater East Asia Coprosperity Sphere would result in conflict with the

¹ Although this section deals in detail only with the Southern and Southwestern Pacific, it is in effect a chronicle of the war against Japan, for events in other areas are treated broadly in their chronological relationship. These events are discussed in detail in sections 10. *War in the Central and Northern Pacific* and 11. *War in Eastern Asia*.

Map 35. JAPANESE PLAN OF EXPANSION. The key to the Japanese dream of a self-sufficient empire was the rich Southern Regions (circled in a broken line on the map), which could provide virtually all of the raw materials required by a highly industrialized state. A defensive perimeter (solid line) was to be established and heavily fortified. A reaction by the United States and Great Britain was expected, but it was believed that after they had battered futilely against the strong defensive perimeter, their will to fight would have been destroyed, and they would be willing to accept a negotiated peace on the basis of the status quo.

Occidental powers. Now the crisis was at hand.

Road to War.—The stringent economic restrictions put into effect by the United States in 1940–1941 made it impossible for Japan to import the raw materials required for war production. She now faced the alternatives of either abandoning her ambitions for empire or making herself self-sufficient through the seizure of the Southern Regions. The former course was unthinkable, while the latter seemed a simple venture under existing circumstances. The British, American, and Netherlands forces confronting Japan were weak. The possibility of British and Dutch reinforcements arriving in strength in Asia or the East Indies was remote, for the Netherlands was in German hands and the British were struggling for survival in the Middle East. Even the USSR was reeling under German attacks. The United States was far from being mobilized and was committed through its lend-lease program to the support of the nations aligned against Germany and Italy.

Certainly the time was ripe for Japan to act with vigor and celerity if her dreams of empire were to be realized. Several years would be required for the United States and Great Britain to muster their full strength in the Pacific, years during which Japan could seize and develop the resources of the Far East and make herself impregnable against counterattack. Four years of campaigning in China had inured her soldiers to the rigors of war. Guns, tanks, planes, and other equipment had been tested in combat. In the many amphibious operations against Chinese ports the Japanese had developed skill in the type of war which they would encounter and had mastered the close coordination of land, sea, and air power.

By Dec. 7, 1941, the Japanese Army had grown to a force of 2,400,000 trained men and 3,000,000 partially trained Reserves. The air fleet consisted of 7,500 planes (including 2,675 first-line planes), which were divided about equally between the army and the navy. The rate of new plane construction was 425 monthly, and additional pilots were being trained at a rate of 2,750 a year. Dissatisfied with the lesser role assigned her by the other powers, Japan in 1934 had denounced the naval agreements of 1922 and 1930, and had secretly increased the strength of her navy to 230 major vessels.

West of Hawaii the Allies could oppose this formidable Japanese war machine with approximately 350,000 poorly equipped ground troops, about 90 warships, and less than 1,000 planes, most of which were obsolete. This force, largely untrained and inexperienced and composed of a mixture of nationalities with divergent customs, languages, and interests, was scattered across the Pacific and Southeast Asia from Wake Island to Burma and from Hong Kong to Australia. The principal centers of Allied strength in the Far East were located in Malaya and the Philippines.

The strength of the Japanese armed forces was enhanced by their strategic disposition. The mandated islands in the Central Pacific, which had been secretly fortified, provided excellent bases for operations to the east against Hawaii, to the west against the Philippines, and to the south against New Guinea, the Solomon Islands, and Australia. American Guam and Wake Island were unfortified and could be taken easily. Bases on the China coast and airfields on Taiwan (Formosa), the Ryukyu Islands, and the home islands provided a safe channel for Japanese ship move-

ments southward. The Japanese occupation of southern French Indochina in July 1941 furnished bases for easy access to Malaya and the key British naval base at Singapore. The Philippines, the principal American outpost in the Far East, were hemmed in on three sides by bases in the Palau group, Taiwan, Hainan, Spratly Island, and French Indochina. Hong Kong, which with Singapore and Manila constituted the foundation of Anglo-Saxon power and influence in the Far East, was isolated by a strong cordon of Japanese troops and by bases on Taiwan and Hainan.

The scene for the drive to the south had been well set, but Japan had her Achilles' heel—her merchant marine, which had grown to 6,100,000 tons. An industrial island nation like Great Britain, she needed to import large quantities of unprocessed materials for home consumption and for the manufacture of war goods; and support of the contemplated military operations would double the burden. Japan could fulfill her shipping requirements as long as undue losses were not experienced, but there was no margin of safety. The ravaging of Japan's merchant marine by American aircraft, submarines, and surface warships was to prove a decisive factor in her eventual defeat.

By December 1941, the United States Army had reached a strength of about 1,500,000 men, of whom 1,000,000 were not completely trained. The Army Air Forces had 1,157 first-line combat aircraft, of which 159 were four-engine bombers. The Navy consisted of 347 warships, and an ambitious expansion program was on the ways. American merchant shipping aggregated more than 10,000,000 tons and was growing rapidly. Nevertheless, the state of American preparedness was gravely affected by the commitment of a large portion of war production to the conflict in Europe.

Japanese War Plan.—As the time for war approached, the military hierarchy dominated Japan economically and politically as well as militarily. The basic war plan of Imperial General Headquarters was divided into three phases. Phase 1 included neutralization of the United States Pacific Fleet at Pearl Harbor, seizure of the Southern Regions, and establishment of a defensive perimeter to protect these regions and the Japanese homeland. Phase 2 consisted of the consolidation and strengthening of the perimeter with a string of fortified bases extending from the Kuril Islands through Wake Island, the Marshall and Gilbert Islands, the Bismarck Archipelago, northern New Guinea, Timor, Java, Sumatra, Malaya, and Borneo. Phase 3 embraced the interception and destruction of any attacking forces that might attempt to penetrate the defensive perimeter, and the waging of a war of attrition to destroy the will to fight of the United States, the principal antagonist.

With her western flank protected by the occupation of the China coast and her northern flank by the neutralization of the USSR through a non-aggression pact, Japan could apply maximum pressure toward the south and east. The only real threat to the Japanese war plan was the United States Pacific Fleet based at Pearl Harbor. The first operation would therefore be the neutralization of this fleet by means of a surprise air attack. The First Air Fleet, a strategically mobile striking force built around 6 fast aircraft carriers, was assigned this task. Once the strike at Pearl Harbor had been successfully completed, strong air

attacks, preliminary to invasion, were to be launched against the Philippines and Malaya to destroy the principal Allied concentrations of air-power in the Far East. Air blows would also be struck against Hong Kong, Wake, and Guam.

The main Japanese attack was to be the drive to seize the Southern Regions. The offensive would begin with a two-pronged thrust, one prong being directed against Malaya and the other against the Philippines. At the same time, Guam, Wake, Hong Kong, British Borneo, and Thailand were to be occupied; and advance bases were to be established in the Bismarck Archipelago, Netherlands Borneo (Kalimantan), Celebes, the Moluccas, and Timor. After the capture of Malaya and the Philippines, the two main forces were to be combined for the invasion of Java, the heart of the Netherlands East Indies. By then the First Air Fleet would have completed its operations in the Central Pacific and could lend its overwhelming power to the assault. At an opportune time, large-scale operations would be undertaken in Burma with the primary object of cutting the Burma Road. Upon the successful completion of these campaigns, the first-phase objectives would have been attained. The second and third phases would follow, and Japan would then revert to the strategic defensive, prepared to counter the eventual assaults of the United States and Great Britain.

This plan for the simultaneous conduct of many far-flung operations violated the cardinal military principle of concentrated application of combat power, but in view of Allied weakness such an unorthodox strategy was sound. Striking everywhere at once not only would exploit the essential element of surprise, but would place the Allies on the defensive on all fronts and confuse them as to the true Japanese objectives. It would take advantage also of the Allies' divergent self-interests and thus hinder any attempt to combine and concentrate available defensive forces during the first phase. The military leaders were confident that once Japan dominated the entire Far East, the Allies, operating at the end of long supply lines and lacking well-developed advance bases, would find reconquest a difficult and prolonged, if not impossible, task.

JAPANESE OFFENSIVES

Early on Sunday morning, Dec. 7, 1941, the First Air Fleet surprised the bulk of the United States Pacific Fleet at anchor in Pearl Harbor and inflicted such damage as to put it out of action as an effective major force for some time. Simultaneously, 2 destroyers attacked the American base at Midway and withdrew after severely damaging its air installations. On December 8, Japanese bombers began to rain destruction on the American garrison of Wake Island. An attempt to land on December 11 was beaten off, but the exhausted garrison succumbed to an overwhelming assault on December 23. From bases on the secretly fortified nearby islands of Rota and Saipan, Japanese aircraft bombed Guam. The small American garrison on the unfortified island was overwhelmed by Japanese troops on December 10. During the month the Japanese also occupied Tarawa and Makin atolls in the Gilbert Islands.

The Japanese attack on Hong Kong came early on December 8 (local time). The British garrison held out until Christmas Day, when, exhausted and without possibility of outside aid, it

surrendered. Simultaneously, Japanese troops moved from their bases in French Indochina to overrun Thailand and advance into Burma, and an amphibious force landed on the east coast of the Kra Peninsula and moved southward into Malaya. On Feb. 15, 1942, Singapore, symbol of British strength in the Far East, fell. By May 20, the Allies had been virtually driven from Burma into India, the Burma Road had been cut, and Southeast Asia was in Japanese hands. The western prong of the offensive had done its work well.

Fall of the Philippines.—The Tydings-McDuffie (Philippines Independence) Act, passed by the United States Congress in 1934, provided for the complete independence of the Philippines after a 10-year period as a commonwealth. Independence was scheduled for July 1946. The fact that the United States intended to withdraw from the islands deterred it from any sizable augmentation of the defensive installations. To assist the Philippines Commonwealth in preparing its own defenses, the United States in 1935 sent Gen. (later General of the Army) Douglas MacArthur to serve as military adviser to the new government. An ambitious program for national defense was initiated in 1936, but it was not far advanced when the Japanese struck in 1941. Japanese encroachments in the years preceding the war had almost surrounded the Philippine Islands. The only line of communication that did not pass through Japanese-controlled waters was to the south, toward the East Indies.

On July 26, 1941, the United States, alarmed by Japan's threatening attitude in the Far East, ordered the embryonic Philippine Army into the service of the Army of the United States, as provided in the Tydings-McDuffie Act. A new headquarters, known as the United States Army Forces in the Far East (USAFEF), was created, with General MacArthur in command. The Regular component of the Philippine Army was inducted immediately, and mobilization of 10 Reserve divisions began. National Guard tank and antiaircraft units were sent from the United States, and in November the 4th Marine Regiment was transferred from Shanghai, China.

By December, Allied ground forces in the Philippines totaled about 130,000 men, 100,000 of whom were hastily mobilized Philippine Army troops lacking training and inadequately equipped. American personnel numbered only 13,507 men, who for the most part were assigned to the 31st Infantry Regiment, and various antiaircraft, armored, and harbor defense units. Other troops consisted of 12,000 dependable Philippine Scouts and 3,000 members of the Philippine Constabulary. The United States Far East Air Force, under the command of Maj. Gen. (later Lt. Gen.) Lewis H. Brereton, comprised 277 aircraft (only 142 of which were suitable for combat) and 5,809 aviation personnel. United States naval strength in the Philippines area consisted of 1 heavy cruiser, 1 light cruiser, 4 destroyers, 28 submarines, 6 gunboats, 28 aircraft, and miscellaneous vessels. This was the major portion of the United States Asiatic Fleet, commanded by Adm. Thomas C. Hart. By this time, approximately 500,000 tons of additional supplies and 20,000 troop reinforcements had been earmarked for dispatch to the Philippines, but the Japanese struck before the first shipments could arrive.

The configuration of the Philippine Archipelago makes it very difficult to defend in its entirety. It comprises about 7,100 islands and islets extend-

Map 36. INVASION OF THE PHILIPPINES (Dec. 10, 1941-Jan. 7, 1942). The initial Japanese landings on Luzon were made at the northern and southern extremities of the island. The object was to draw the defenders to these areas so that, when the main landings were made at Lingayen Gulf and Lamon Bay in central Luzon, Gen. Douglas MacArthur's forces would be separated in isolated areas and subject to easy destruction. This strategy did not deceive MacArthur; he kept his forces closely under control and gradually conducted an orderly withdrawal toward Bataan Peninsula in accordance with the basic war plan.

ing approximately 1,100 miles from north to south and 700 miles from east to west. The problem of defense resolved itself into an effort to hold only the largest and most important land areas, particularly Luzon and Mindanao.

A fundamental weakness of the Philippines was its dependence on the outside world. Though possessing rich natural resources, it lacked heavy industries and munition plants and had only a few factories capable of supplying even the smallest items of military equipment. Gasoline and oil had to be imported. Once cut off from outside assistance, the defenders of the islands could not long endure.

Capture of Luzon.—General MacArthur's plan was to make his principal defense on Luzon, the largest and most important island of the group. All but three Philippine Reserve divisions and some miscellaneous troops were concentrated there. Except for 16 heavy bombers and a squadron of Navy patrol bombers, which were in Mindanao, the entire air force was also based on Luzon. A war warning had been received on November 27, and because of the lack of air protection Admiral Hart had moved most of the warships of the Asiatic Fleet out of Manila Bay.

For the defense of Luzon, MacArthur had organized three field forces: the North Luzon Force, the major defense unit, consisting of three Philip-

pine Reserve divisions and elements of the Philippine Scouts, which was under the command of Maj. Gen. (later Gen.) Jonathan M. Wainwright; the South Luzon Force, composed of two Philippine Reserve divisions, elements of the Philippine 1st Regular Division, and two regiments of the Constabulary, commanded by Brig. Gen. (Later Maj. Gen.) George M. Parker, Jr.; and the USAFFE reserve, which was retained directly under MacArthur's command and included the Philippine Division, two Philippine Reserve divisions, two American tank battalions, and miscellaneous other units. The nucleus of the entire force defending Luzon was the Philippine Division. It included two first-rate Philippine Scout infantry regiments, the American 31st Infantry Regiment, and a full quota of division artillery. Two other forces had also been formed: the Philippine Coast Artillery Command, comprising all coast and antiaircraft artillery, which was charged primarily with the defense of Manila and Subic bays; and the Visayan-Mindanao Force, which was responsible for the defense of the southern islands. The plan of defense was to fight as strong a delaying action as possible, retiring as it became necessary to the Bataan Peninsula and the forts of Manila Bay, where a final stand would be made until the United States Navy brought aid.

The Japanese Fourteenth Army, commanded by Lt. Gen. Masaharu Homma and consisting of two reinforced divisions, the 16th and the 48th, was assigned to the invasion of the Philippines. These divisions were well trained and had had fighting experience in China. Each comprised almost 50,000 men and as many as 100 tanks. The 48th Division was to land in northern Luzon and the 16th in southern Luzon; both were to converge on Manila. Meanwhile, elements of the 16th Division would invade Mindanao. The bulk of the Japanese Third Fleet—5 cruisers, 14 destroyers, 1 seaplane carrier, and a host of auxiliaries—was designated the Northern Philippine Force and assigned to support the attack on northern Luzon. The Southern Philippine Force, consisting of the rest of the Third Fleet plus a carrier division—2 aircraft carriers, 5 cruisers, 13 destroyers, 2 seaplane carriers, and a large number of transports and supply ships—was assigned to support the landings in southern Luzon and in the Mindanao-Sulu Archipelago area. Once the landings in Malaya had been successfully carried out, the roving Japanese Second Fleet—2 battleships, 3 cruisers, and 4 destroyers—would provide added support for the main landing on northern Luzon.

The first task of the Japanese was to destroy American airpower and air installations and to seize airfields for land-based aircraft. Since army aircraft based on Taiwan could barely reach Luzon, navy planes had to be used for the main strikes until airfields in the Philippines had been captured. The plan was to strike at dawn on December 8 with a force of 84 fighters and 107 bombers, but a heavy fog blanketed the fields on Taiwan that morning, and the first aircraft did not leave until 10:15 A.M. The Japanese aircraft appeared over Luzon shortly after noon. The delay in attacking proved fortuitous for Japan. Since MacArthur had been informed at 3:30 A.M. that a state of war existed, his planes were in the air at dawn seeking the enemy, and a number of false alerts kept them busy for most of the morning. When the Japanese planes arrived, many of the American fighters were in the process of landing for refueling, others were grounded at airfields because of dust, and the bombers were on the ground. The Japanese therefore encountered little resistance and proceeded to wreak havoc on the American aircraft, and installations. The airfields on Luzon were virtually put out of action, and the naval base at Cavite was destroyed. By the end of the day half of the American bomber force and a third of the fighters had been destroyed. Possessing mastery of the air, the Japanese continued their destructive attacks during the succeeding days. The 16 remaining American bombers were withdrawn on December 11 to Mindanao, and then to Australia, without having been able to mount a single effective strike. By December 15, American fighters had been reduced to a handful, and these were now husbanded for reconnaissance purposes.

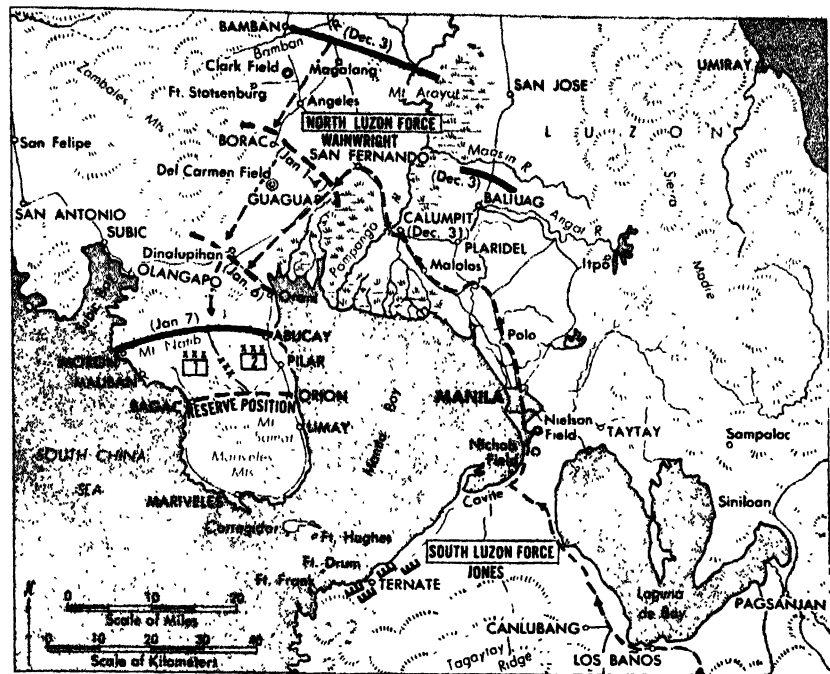

At dawn on December 10, the first Japanese landings took place at Aparri and Vigan in northern Luzon. Elements of the 48th Division, consisting of about 2,000 men each, went ashore at the two points. Early on December 12, 2,500 men of the 16th Division landed at Legaspi in southern Luzon. These landings were designed to lure the defenders to the extremities of the island so that, when the main forces debarked in central Luzon, MacArthur's forces would be divided and

isolated. The general did not succumb to this strategy. Instead, he allowed the small forces in the areas concerned to delay the Japanese as best they could; attacked the Japanese naval forces supporting the landings with his meager air force, though with negligible results; and held his troops close in hand, awaiting the main landings. These came at Lingayen Gulf early on December 22 and at Lamon Bay before dawn on December 24.

Initially, MacArthur's plan had been to meet the Japanese at the beaches and drive them back into the sea. Since this was obviously impossible with the limited combat strength available, his troops had been ordered to hold certain lines inshore and delay the enemy. Thus, when the bulk of the 48th Division (43,110 men and from 80 to 100 tanks) landed at Lingayen Gulf, it encountered little opposition. General Wainwright's North Luzon Force braced itself to meet the inevitable onslaught. The Regular units fought well and offered stiff resistance, but the inexperienced Philippine Reserve divisions were no match for the battle-hardened Japanese troops. Constantly threatened with outflanking on the east, the North Luzon Force gradually gave ground. On December 31, Wainwright's troops were holding desperately to the Bataan-Mount Arayat line and at Baliuag in order to keep open the only escape route into the Bataan Peninsula for the South Luzon Force. This force, which was threatened with outflanking on the south on the very first day, had been falling back toward Manila. On December 24, MacArthur ordered General Parker to prepare the defensive positions on Bataan. Maj. Gen. Albert M. Jones took command of the South Luzon Force. These troops passed around Manila on the night of December 30, and by dawn of the next day had crossed the dangerous bottleneck of the Calumpit bridges, which had been kept open by Wainwright's troops. (Manila itself had been declared an open city on December 26, but it was bombed repeatedly by the Japanese during the succeeding days.) On Jan. 1, 1942, Wainwright withdrew his forces to the Borac-Guagua line covering Bataan. There two Philippine divisions held off Japanese attacks until January 4 in order to allow the rest of MacArthur's forces to get into position on Bataan and prepare for the defense of the peninsula. By January 7, USAFFE was in position and organized for defense, with the forward line extending from Moron through Mount Natib to Abucay.

Fall of Bataan and Corregidor.—Behind the forward defense line the USAFFE forces were organized into two corps. The 1st Corps, under General Wainwright, held the western sector, while the 2d Corps, under General Parker, defended the eastern sector. A reserve battle position extended from Bagac to Orion, and behind a line running roughly through Mariveles was the Service Command Area. The USAFFE reserve, consisting of elements of the reliable Philippine Division, was behind the reserve battle position in General Parker's sector, the sector containing the best routes for the Japanese advance. The forces on Bataan totaled about 80,000 men, including 15,000 Americans. Approximately 2,000 troops, who had been cut off in the retreat to Bataan, fled to the hills of Luzon and conducted guerrilla warfare. Food, housing, and sanitation problems on Bataan were greatly complicated by the presence of more than 26,000 civilian refugees, a contingency that had not been foreseen in planning the defense of the peninsula. All troops were

Map 37. FALL OF BATAAN AND CORREGIDOR (Jan. 1-May 6, 1942). Maj. Gen. Jonathan M. Wainwright held the escape route over the Calumpit bridges open for the South Luzon Force; then all retired to the defenses of Bataan. With no possible hope of outside assistance, the Filipino-American forces fought stubbornly for four months, encumbered by thousands of civilian refugees. Starvation, disease, and lack of supplies and munitions gradually reduced them to impotence. Overwhelmed, they surrendered on May 6.

immediately placed on half rations. With the United States Pacific Fleet virtually immobilized after the attack on Pearl Harbor and the Japanese in control of the waters surrounding the Philippines, the Bataan garrison would have to fight it out with its own limited resources.

Japanese probing attacks against the forward line began on January 9. Determined to conclude the Bataan campaign expeditiously, General Homma began to apply relentless pressure on January 10. The crisis came on January 22, when penetrations on both flanks of the forward line made the position untenable despite vigorous Allied counterattacks. A withdrawal to the reserve battle position was ordered and was completed by daylight on January 26. Meanwhile, on January 23, the Japanese began a series of landings on the southeastern tip of Bataan. Initially, they were opposed only by miscellaneous troops in the vicinity of the landings. Constabulary, Air Corps personnel, sailors, and Marines, organized into provisional units, held the invaders at the beaches until two regiments could be brought up from the front. These struggles, known as the Battle of the Points, continued until February 13, when the last of the Japanese were driven into the sea.

Concurrently with the amphibious landings in the south, General Homma launched an attack on January 26 against the 1st Corps sector, during which a Japanese regiment passed almost unnoticed through the Allied lines and reached an area deep in the rear. General Wainwright executed a series of counterattacks in what became known as the Battle of the Pockets. The Japanese resisted stubbornly, and it was not until mid-February that the pockets had been reduced and the battle position restored. In the meantime, Japanese attacks were made in the 2d Corps sector on January 27 and 28, but these were repulsed. The collapse of his offensive was a severe shock to General Homma. Operations in every other theater were meeting with phenomenal success, particularly in Malaya, where Singapore had fallen

with a bag of 73,000 prisoners. Since Homma had been required to relinquish one of his divisions for scheduled operations in Java, his effective fighting strength had been so much reduced that it was necessary to suspend offensive operations for the time being. Moreover, he had already suffered 7,000 casualties, and between 10,000 and 12,000 of his men were hospitalized with tropical diseases.

Homma counted on a scarcity of food to weaken the defenders of Bataan while he awaited reinforcements, and his hopes were realized. Stocks for the 78,000 troops and 26,000 civilians on Bataan dwindled steadily. An occasional submarine arrived with food, but more often the cargo consisted of much-needed drugs or ammunition. Malnutrition led inevitably to physical wastage and greater susceptibility to disease. Vitamin deficiency caused the almost universal spread of beriberi, while every day hundreds of soldiers suffering from malaria, dysentery, or hookworm were admitted to field hospitals. By March 11, the troops were on one-third rations, and offensive action by the half-starved forces was no longer practicable.

On February 22, President Franklin D. Roosevelt ordered General MacArthur to proceed to Australia to become supreme commander of the Allied forces in the Southwest Pacific. He left on March 11, and General Wainwright took command of the newly constituted Luzon Force, comprising all troops on Bataan. General Jones succeeded to the command of Wainwright's 1st Corps. On March 19, Wainwright was promoted to the rank of lieutenant general and became commander of the United States forces in the Philippines; Maj. Gen. Edward P. King, Jr., took over command of the Luzon Force.

Homma began to receive a steady stream of reinforcements, and by mid-March the increased activity of Japanese aircraft and artillery pre-saged a new offensive. Probing attacks began on the left of the 2d Corps sector on March 27, and

pressure there grew steadily until April 3. Then, with heavy air, artillery, and tank support, the Japanese infantry attacked in strength. The Allied troops, now on quarter rations, counterattacked as best they could but were unable to prevent the collapse of the 2d Corps' left flank. Virtually all of the 1st Corps was moved to the 2d Corps sector in an attempt to stem the Japanese advance, but had little success. Gradually the troops were driven down the east coast of Bataan until, on April 9, General King, realizing the hopelessness of the situation, surrendered the Luzon Force to General Homma. The latter, who had expected the surrender of all troops in the Philippines, was furious when he learned that King spoke only for the Luzon Force. The Bataan garrison then began its long death march to Camp O'Donnell in central Luzon. It is known that on May 10 about 45,000 Filipino soldiers and 9,300 Americans were imprisoned in the camp; the remainder of the Bataan troops perished in the last fighting or during the death march and subsequent incarceration at Camp O'Donnell. A handful escaped to the hills to carry on as guerrillas.

Japanese attention was now focused on Corregidor, the last Allied stronghold in the Philippines. The island, which lies off the southern tip of Bataan, was the key bastion in the chain of island forts that stretched across the 11-mile entrance to Manila Bay. With the fall of Bataan, the Japanese lost no time in moving their artillery to Mariveles on the south coast. Then began an intensive bombardment, in which heavy guns on the south shore of Manila joined. By April 14, most of the fixed guns on Corregidor had been put out of action. Enemy aircraft supplemented the shelling with incessant bombing attacks that contributed impressively to the destruction of the matériel and morale of the defenders. Artillery fire continued throughout most of each day. It was estimated that on May 4 alone more than 16,000 shells hit Corregidor.

On May 5 and 6, Japanese landing barges approached the northern shores of the island. The Allied light field guns, which had been kept protected from bombardment, went into action and

sank many of the barges, but the Japanese gained a foothold ashore. Wishing to end hostilities before nightfall (since his enemy by then might be among the many sick and wounded in Malinta Tunnel), General Wainwright offered the surrender of Corregidor to General Homma on the afternoon of May 6. The Japanese commander insisted on the surrender of all troops in the Philippines. The situation was such that the American commander had no choice; he complied at midnight, May 6. The 11,500 surviving Allied troops, exhausted by incessant bombardment and undernourishment, were evacuated to a prison stockade in Manila.

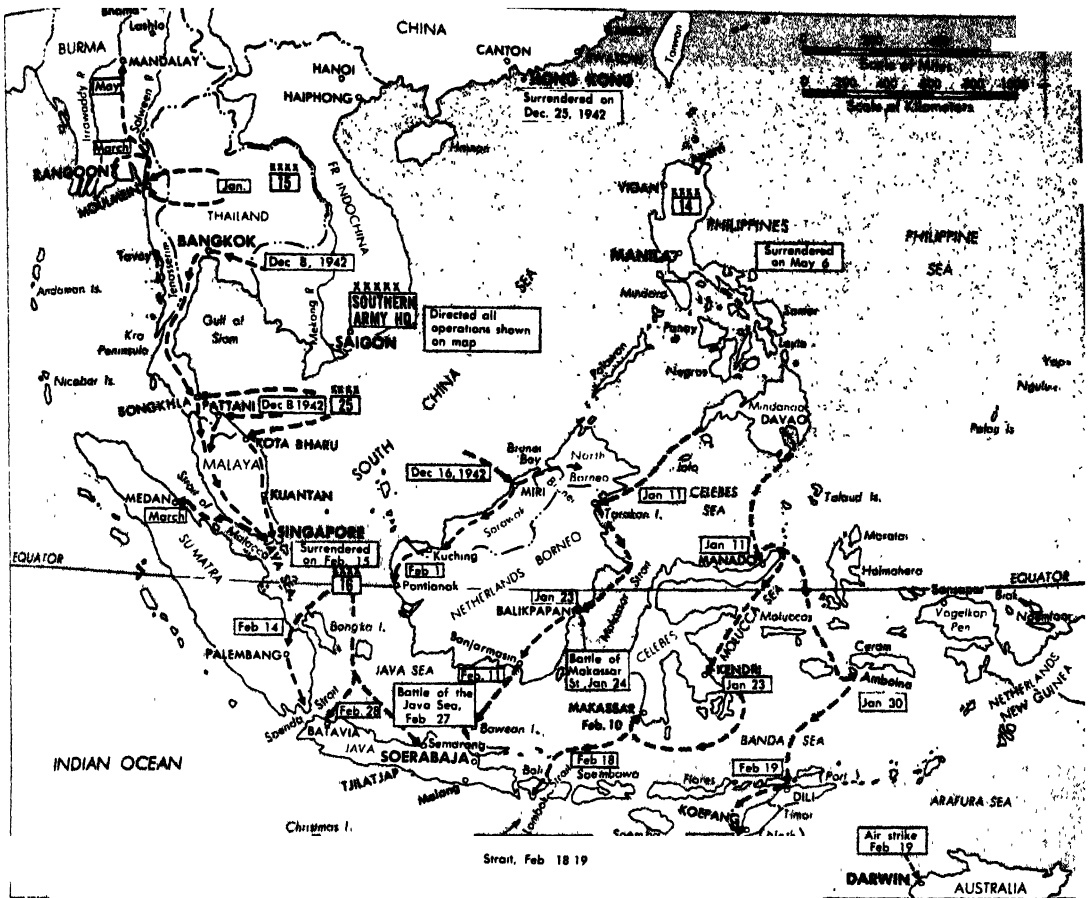

Capture of the Southern Philippines.—The operations that took place on the southern islands concurrently with those on Luzon were comparatively small. The principal objective of the Japanese in this area was to seize bases for the support of the coming invasion of the Netherlands East Indies. They were content to capture initially the most important points on the major islands, leaving the interior areas to be mopped up later. The defense of the southern Philippines was entrusted to the Visayan-Mindanao Force, commanded by Col. (later Maj. Gen.) William F. Sharp. This force consisted of the equivalent of four Philippine Reserve divisions and a regiment of Constabulary troops; it had practically no artillery. Most of the troops were posted on Mindanao, part of one division held Cebu, and part of another defended Panay. On December 8, aircraft from 2 small Japanese carriers struck Davao, principal city of Mindanao, inflicting considerable damage on the few military installations there and destroying 2 long-range naval patrol bombers. The Japanese landed in strength near Davao on December 20, two days before the main landing on Luzon; drove off the weak Allied resistance, and, with the aid of the many Japanese civilians living in and about the city, established a firm perimeter defense around Davao and the adjacent airfield. On Christmas Day, the Japanese occupied the island of Jolo and began the construction of a large air base. On December 31, another beachhead was established on Mindanao, at Digos. While these operations were in progress, American long-range Army bombers, based at Darwin, Australia, and Navy patrol bombers, based at Ambonia (now Ambon), Netherlands East Indies, made limited attacks on Japanese shipping supporting the landings, but without substantial results.

When General Homma realized that the capture of Bataan was not enough to force the surrender of all the Philippines, he sent additional troops to crush resistance in the other islands. Cebu was assaulted on April 10, and Panay on April 16, and additional landings were made on Mindanao: near Cotabato on April 29, and at Cagayan on May 3. The Visayan-Mindanao Force, only partially trained and fighting without artillery, could offer little effective resistance to the determined Japanese attacks. Gradually, the troops moved back into the hills to conduct guerrilla operations. On May 6, General Wainwright had agreed to surrender all troops in the Philippines. Fearing reprisals against the Luzon and Corregidor troops already surrendered, he sent couriers to the island commanders in the south, instructing them to capitulate. General Sharp accordingly surrendered the forces on Mindanao on May 10; three days later, Brig. Gen. Bradford G. Chynoweth surrendered the troops on Cebu and

Corregidor surrendered to the Japanese at midnight, May 6, 1942. Here its heroic American defenders, exhausted by their long ordeal, are being marched to captivity.

Wide World

Map 38. CONQUEST OF THE NETHERLANDS EAST INDIES (Jan. 11–March 9, 1942). Except in the Philippines, the offensives of the Japanese progressed so well that they were able to begin operations in the Netherlands East Indies sooner than scheduled. The Allies concentrated such air and naval forces as they could for the defense of the Indies, but they were gradually overpowered by greatly superior forces. On March 9, the Dutch surrendered the islands to the Japanese. The map shows the successive Japanese landings in the Indies; it also shows schematically the opening operations on the Southeast Asian mainland.

Panay. Many civilians and troops who did not choose to surrender fled into the hills and organized guerrilla bands.

Conquest of the Netherlands East Indies.—The East Indies comprised the richest portion of the Southern Regions. The Japanese conquest of this prize would have to await the end of the campaigns in Malaya and the Philippines, when adequate forces and bases would become available. The problems of defending the Indies were much the same as those encountered in the Philippines. The string of islands extends east and west for about 3,000 miles. Java, the most populous island, was highly developed, but the other islands were generally undeveloped and had limited land communications. A gigantic army would be needed to defend all of them. In December 1941, the Dutch Army in the Indies numbered about 140,000 men, who were concentrated mainly on Java. These were mostly native troops, poorly equipped and of uncertain combat efficiency. Available Dutch naval forces included 3 cruisers, 7 destroyers, and 16 submarines. The principal naval base was at Soerabaja (now Surabaya), Java. About 150 aircraft of all types, generally obsolete, provided the air defense of the entire

Netherlands East Indies. Airfields were situated at key points on all major islands, with the largest bases on Java.

When the United States Asiatic Fleet withdrew from the Philippines, it began to operate from Soerabaja. Meanwhile, American Flying Fortress bombers that had withdrawn from the Philippines to Australia prepared to move into the Dutch air bases. By the end of 1941 the Allied situation in the Far East was deteriorating rapidly. Hong Kong had fallen, Allied troops in the Philippines were being compressed onto the Bataan Peninsula, Singapore was in grave danger, and the Japanese had established strong bases in northern Borneo and the southern Philippines. Under this pressure, Allied cooperation began to show signs of strain: the Australians urged adequate defense of their country, the British stressed the importance of holding Singapore, the Americans sought reinforcements for their beleaguered troops in the Philippines, and the Dutch pressed for assistance in the defense of the Indies. In an attempt to unify the direction of the Allied war effort in the Far East, Gen. (later Field Marshal) Sir Archibald Wavell (later 1st Earl Wavell) was designated supreme commander for all American,

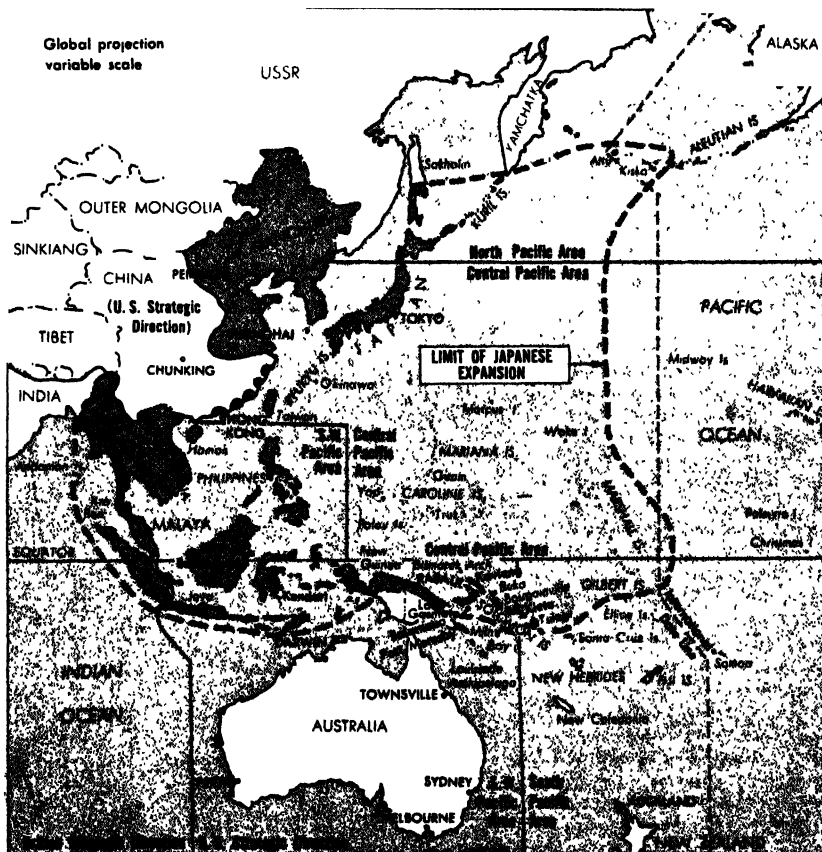

British, Dutch, and Australian forces. Wavell named his forces the American-British-Dutch-Australian Command (ABDACOM). Allied defensive strategy was now directed toward holding the Malay barrier, which was defined as the Malay Peninsula-Sumatra-Java-northern Australia line, with Burma and Australia as the essential supporting positions on its flanks. Communications with Luzon were to be reestablished and kept open through the northern Indies. The British sent reinforcements to Malaya and Burma and arranged for the return of two Australian divisions from the Middle East, and the United States made every effort to dispatch troops, supplies, and aircraft to the Indies.

All of these efforts were in vain. The rapidity of Japanese successes in the initial offensives made it possible to begin operations against the Indies sooner than had been expected. On Jan. 11, 1942, the first attacks were launched—at Tarakan, the Borneo oil port, and at Manado (Menado), a key base in Celebes. Succeeding landings are best shown on Map 38. At all places the Japanese easily overcame Dutch resistance. The small Allied air force could do little against greatly superior Japanese airpower. Allied naval strength in the area consisted of only 9 cruisers, 23 destroyers, and 36 submarines. Nevertheless, though no match for the vastly superior Japanese Fleet, the Allied warships attacked repeatedly. In the early dark hours of January 24, 4 Allied destroyers attacked a large convoy off Balikpapan, Borneo. In this, the Battle of Makassar Strait, the destroyers escaped unharmed after sinking 4 Japanese transports and a patrol ship and damaging

other vessels. Subsequent engagements—the Battle of Lombok Strait (February 18-19) and the Battle of the Java Sea (February 27)—were not as successful for the Allies. In the latter losses from Japanese air and naval attacks were so severe that the surviving Allied warships were withdrawn from the Java Sea to Tjilatjap (Chilachap) on the south coast of Java. On February 28, 2 Allied cruisers, the *Houston* and the *Perth*, which were attempting to escape southward through Soenda (now Sunda) Strait, suddenly ran into a huge Japanese invasion armada in the process of assaulting Batavia (now Djakarta). The cruisers were destroyed, but only after sinking 3 loaded Japanese transports.

The few Allied aircraft and warships that remained were ordered to withdraw to Australia. On March 9, the Dutch finally surrendered the Netherlands East Indies to the Japanese. Allied attention was now directed to the defense of Australia. The enemy was not far away.

Establishment of the Defensive Perimeter.—The Bismarck Archipelago, northeastern New Guinea, and Bougainville and Buka in the Solomon Islands were all mandated to Australia after World War I. The rest of the Solomon Islands constituted a British protectorate, and Papua (southeastern New Guinea) was an Australian territory. Dominating the northern shores of the Coral Sea, these islands provided excellent bases for attacks on Australia and the supply lines from the United States, which now ran a circuitous route through New Caledonia, Fiji, and Samoa to Hawaii. The principal Japanese objective in the area was Rabaul in the Bismarcks. It

Map 39. LIMIT OF JAPANESE EXPANSION (Aug. 6, 1942). The map shows the maximum extent of the Japanese conquests (heavy broken line and shaded areas). It also shows the United States and British spheres of strategic direction and the division of the American sphere into North, Central, South, and Southwest Pacific areas.

had a splendid natural harbor, the contiguous terrain was ideal for airfields, and from it control could be exercised over the area bounded by New Guinea, the Bismarck Archipelago, and the Solomon Islands.

While Japanese forces in the Netherlands East Indies were pouring ashore at Balikpapan and Kendari, Celebes, on January 23, their Fourth Fleet was engaged in assaulting Rabaul, Kavieng, and Kieta. The only opposition encountered was at Rabaul, where 1,400 Australian troops opposed more than 4,000 Japanese. About 400 of the defenders eventually escaped to Australia. Gasmata, New Britain, was occupied on February 8, and on the night of March 7-8, landings were made at Lae and Salamaua on the north coast of New Guinea. The Allies countered with an air attack on Rabaul by 6 bombers of the United States Fifth Air Force, based at Townsville, Australia, and a daring air strike by an American carrier-aircraft task force over the high mountains of New Guinea against Japanese shipping at Lae and Salamaua. Some damage was inflicted, but the Japanese occupation was not hindered. The Pacific defensive perimeter, as envisioned by the basic war plan of Japanese Imperial General Headquarters, had now been established.

Expansion of the Defensive Perimeter.—It was now time for the second phase of the Japanese war plan, consolidation and strengthening of the defensive perimeter, but the unexpected ease with which the initial offensives had been carried out lured the Japanese High Command into a program of further expansion. It was decided to occupy the Solomon Islands and Port Moresby, Papua, in order to strengthen the original perimeter through New Guinea and the Bismarcks. These conquests would pave the way for the subsequent occupation of New Caledonia, Fiji, and Samoa, thus severing the supply lines between the United States and Australia. Expansion of the perimeter to include the Midway Islands in the Central Pacific and Attu and Kiska in the Aleutian Islands was also contemplated.

The first operation was the capture, on May 3, of Tulagi in the southern Solomons. By July, all of the major islands of the Solomon group had been occupied by the Japanese. A strike by an American naval carrier task force against the invading convoy at Tulagi sank or damaged several destroyers and a number of smaller vessels with a loss of only 3 planes. Forewarned that a strong amphibious force was to move through the Coral Sea to occupy Port Moresby, Allied naval forces assembled for the approaching battle. (The Americans had broken the Japanese secret code before the outbreak of the Pacific war and often gained valuable information on impending operations.) The invasion armada was discovered by scouting planes off the Louisiade Archipelago on May 7, and Rear Adm. (later Vice Adm.) Frank J. Fletcher moved his American task force northward. About noon, his carrier aircraft attacked and sank a Japanese escort carrier. Early on the next day, the opposing carrier groups located each other and launched their aircraft for what was to be the first carrier-against-carrier battle in history and the first major naval battle to be fought without an exchange of shots by surface ships. In the resulting engagement, American planes damaged 1 Japanese carrier, while the Japanese inflicted damage to both American carriers, the *Yorktown* and the *Lexing-*

ton. The latter was so badly damaged that she had to be sunk. In this two-day Battle of the Coral Sea, the Japanese lost 105 carrier aircraft; the Americans, 81. Tactically, the engagement was a draw; strategically, it was an important American victory, because the Japanese turned about and abandoned their amphibious operation against Port Moresby.

Again by virtue of knowledge of the Japanese code, it was learned that a gigantic operation was planned to occupy Midway and destroy American naval strength in that area. Admiral Fletcher left the Coral Sea and hastened to join the naval forces of the Central Pacific for the coming battle. Meanwhile, General MacArthur set about strengthening Port Moresby and other bases in eastern New Guinea and established an air base at Milne Bay.

RECOVERY AND VICTORY OF THE ALLIES

The stunning defeat inflicted on the Japanese Navy at Midway in June 1942 caused the American Joint Chiefs of Staff to order the adoption of a more aggressive policy for the South and Southwest Pacific. The overextension of the Japanese in their widespread operations made this policy feasible. The Japanese were faced with the difficulty of supplying troops thousands of miles from home and along a front that extended from India through Malaya, the Netherlands East Indies, New Guinea, and the Solomons, and thence northward through the Gilbert Islands to the Aleutians. Allied submarines and planes had taken an increasingly larger toll of shipping as the months went by, and the speed that had characterized early Japanese operations could no longer be maintained because there were fewer ships to cover greater distances.

The operations prescribed by the Joint Chiefs of Staff envisaged a two-pronged offensive, with one prong directed toward northern New Guinea from Port Moresby and the other up the chain of the Solomons. The final objective of both drives was the recapture of Rabaul, the principal Japanese base in the Southwest Pacific. These two offensives, the Guadalcanal campaign in the Solomons and the Papuan campaign in New Guinea, were the first Allied steps on the road that was to lead to Tokyo.

Guadalcanal Campaign.—Japanese troops and construction personnel had landed on the north shore of Guadalcanal on July 6, 1942, and had begun to develop an airfield and a base for subsequent operations. The American objective was to seize these installations and drive the invaders from the island. Vice Adm. Robert L. Ghormley, commander of the South Pacific Area, with headquarters at Auckland, New Zealand, planned and exercised over-all direction of the Guadalcanal offensive. Admiral Fletcher commanded the two task forces to be employed: the Amphibious Force and the Air Support Force. The Amphibious Force, under Rear Adm. (later Adm.) Richmond K. Turner, was composed of transport and naval support groups aggregating 23 transports, 8 cruisers, 15 destroyers, and 5 minesweepers. Aboard the transports were the 1st Marine Division, the 2d Marine Regiment of the 2d Marine Division, and other troops totaling 19,500 men, commanded by Maj. Gen. (later Gen.) Alexander A. Vandegrift. The Air Support Force consisted of 3 large carriers (the *Saratoga*, *Enterprise*, and *Wasp*), the battleship *North Carolina*, 6 cruisers, and 16 destroyers. This force, under Rear Adm.

Leigh Noyes, was to provide air support for the assault and security against hostile air attack. All land-based planes in the South Pacific (a total of 291, including Army planes) were to be controlled by Rear Adm. (later Vice Adm.) John S. McCain, air commander under Admiral Ghormley.

General MacArthur agreed to use Southwest Pacific air forces to interfere with any Japanese attempt to send reinforcements from Rabaul and to keep that base under strong air attack during the American landings on Guadalcanal. Adm. (later Admiral of the Fleet) Chester W. Nimitz, commander in chief of the Pacific Fleet, agreed to post submarines to interfere with any dispatch of reinforcements from the Japanese base on Truk.

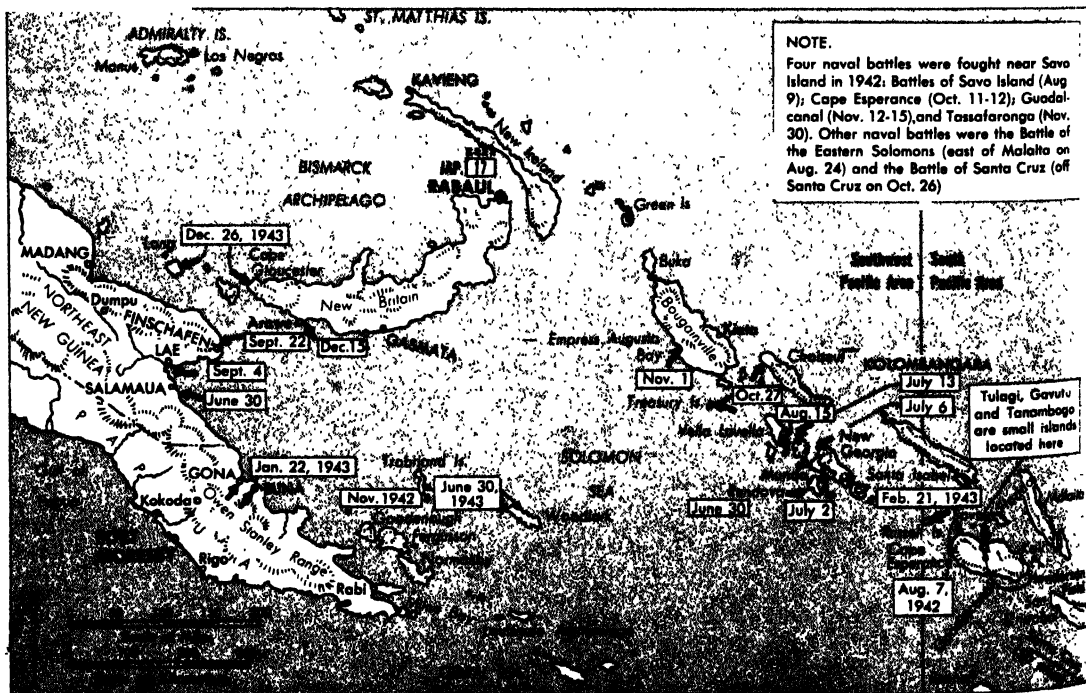

On August 6, as the American invasion fleet approached Guadalcanal from the south, there were actually only 1,500 Japanese in the Tulagi area and about 2,230 on Guadalcanal itself, concentrated near the airfield. Of these, 600 and 1,700, respectively, were labor troops of inferior fighting quality. Heavy air and naval bombardment preceded the landings, which were made on schedule the next morning. Tulagi, Gavutu, and Tanambogo islands, in the Florida group opposite the north coast of Guadalcanal, were captured by the morning of August 8 despite do-or-die fighting by the Japanese. The landings on Guadalcanal were unopposed, and the Marines moved inland without making contact with the Japanese on the first day. On August 8, the advance continued, the airfield (later named Hen-

derson Field in honor of a Marine Corps pilot hero of the Battle of Midway) was captured, and a defensive perimeter established around it, all against light opposition.

The American occupation of Guadalcanal provoked a violent reaction by the Japanese. They seem to have attached great importance to its recovery, for a captured Japanese document reads in part: "Success or failure in recapturing Guadalcanal . . . is the fork in the road which leads to victory for them or for us." Guadalcanal was to be a magnet that attracted powerful Japanese forces and a sinkhole in which they were dissipated. Costly naval battles were to be fought for three months, and the bitter struggle on the ground was to continue for half a year.

Despite the efforts of MacArthur's planes to keep Rabaul neutralized, large bomber groups were launched from the base to attack the American ships off Guadalcanal. Although many planes were destroyed, the attacks were renewed repeatedly. On the morning of August 8, the carriers of the Air Support Force retired to the south, and it was decided to withdraw all the other ships, including those of the Amphibious Force. Their departure was accelerated by a surprise night raid early on August 9 against American warships off Savo Island. In this Battle of Savo Island, 4 American cruisers were sunk, and 1 cruiser and 2 destroyers were damaged. The Japanese ships escaped without harm. Thus the Marines were left ashore without naval or air support and with meager supplies. Under the

Map 40. ALLIED VICTORIES IN NEW GUINEA AND THE SOLOMON ISLANDS (August 1942–December 1943). In August 1942, American troops took the offensive and invaded Guadalcanal. The Japanese poured reinforcements into the island, and one of the most bitter battles of the war ensued. Eventually the Japanese were defeated with heavy losses. South Pacific forces then began a long hard drive up the Solomon chain, as shown. By the end of 1943 they were in possession of the Solomons. Meanwhile, Southwest Pacific forces had taken up the offensive in Papua and northeastern New Guinea. They drove the Japanese from their principal bases at Buna and Gona and continued the offensive along the northeast coast of New Guinea. Rabaul, New Britain, the key Japanese base, was virtually encircled and isolated by these drives. The Allies had wrested the initiative from the Japanese and were to hold it for the remainder of the war.

United States Marines search a palm grove on Guadalcanal for Japanese snipers and stragglers soon after they landed on the island on Aug. 7, 1942.

Wide World

circumstances, General Vandegrift could do no more than concentrate his forces for the defense of the perimeter surrounding Henderson Field and request reinforcements.

On August 18, the first Japanese reinforcements, totaling approximately 1,000 men, arrived on the island. They attacked the Marines on August 21 and were almost annihilated. Meanwhile, on August 20, 19 Marine Corps fighters and 12 dive bombers arrived at Henderson Field; two days later, the first 5 Army planes landed.

A huge Japanese invasion fleet had left Rabaul on August 19 under continuous cover by land-based aircraft. It comprised 3 carriers, 8 battleships, 6 cruisers, 21 destroyers, and 4 troop transports. American forces gathered to intercept it, but all that could be mustered were 2 carriers, 1 battleship, 4 cruisers, and 10 destroyers. Also available were 36 planes on Guadalcanal and 69 long-range patrol bombers. In the ensuing Battle of the Eastern Solomons, fought on August 24, airpower decided the issue. The Japanese, all but stripped of their carrier aircraft, broke off the fight and withdrew. They had lost 1 carrier, 1 cruiser, and 1 destroyer; 1 seaplane carrier and 1 light cruiser were damaged; and about 90 of their aircraft were shot down. American losses consisted of 1 carrier (the *Enterprise*) damaged and 20 planes destroyed.

The Japanese now began to reinforce Guadalcanal by means of fast destroyers, the decks of which were loaded with men and equipment. These approached the island under cover of darkness, unloaded, and sped away before dawn. Troops and equipment were also moved in large landing craft from island to island down the chain of the Solomons, sailing by night and hiding by day. Between August 29 and September 11, approximately 6,000 troops were landed by these means. On September 13 and 14, the Japanese made determined attacks against the Marine position on Bloody Ridge but were repulsed with heavy losses. It now became evident to the Japanese that large forces, tanks, and artillery were needed to dislodge the Marines. The Seventeenth Army, with headquarters at Rabaul, was formed under Lt. Gen. Haruyoshi Hyakutake. The "Tokyo Express," as the swift-moving convoys of troop-ferrying destroyers and cruisers came to be known, operated almost nightly during the latter part of September and early October, building up Japanese strength on Guadalcanal. Meanwhile, the Marines were being reinforced. On September 18, the 7th Regiment

of the 1st Marine Division arrived. Additional squadrons of fighters and dive bombers came to Henderson Field. Coast defense guns were emplaced, and more supplies and equipment reached the troops. On October 13, the 164th Infantry Regiment of the Army Americal Division also arrived.

During the period October 23-26, mostly days of torrential downpours, General Hyakutake made his final bid for victory. Heavy artillery shelled Henderson Field almost incessantly. At times the heavy rains turned the airfield into a sea of mud, preventing American aircraft from leaving the ground and giving the Japanese free rein in the air. But the frequent and violent tank-infantry attacks were beaten back with heavy losses. After a last futile effort on the night of October 25-26, Hyakutake abandoned the land offensive and, on about October 29, began a general withdrawal. General Vandegrift now moved westward to drive his enemy out of artillery range of Henderson Field.

In the meantime, persistent efforts by the Japanese Navy to reinforce the island resulted in a number of naval engagements. During the night of October 11-12, a Japanese force of 4 cruisers and 1 destroyer was intercepted and surprised by Rear Adm. Norman Scott's task force of 4 cruisers and 5 destroyers. In the resulting Battle of Cape Esperance the Japanese lost 1 cruiser and 1 destroyer sunk and 2 cruisers damaged. American losses consisted of 1 destroyer sunk and 2 cruisers and 1 destroyer damaged. As the battle ashore reached its peak on October 26, the two navies clashed in the Battle of Santa Cruz north of the Santa Cruz Islands. The Japanese armada consisted of 4 carriers, 4 battleships, 9 cruisers, 28 destroyers, and 7 other vessels. The much weaker American task force comprised 2 carriers, 1 battleship, 6 cruisers, and 14 destroyers. In this one-day naval-air battle, 3 Japanese carriers and 2 destroyers were damaged, but none were destroyed, although about two thirds of the 170 to 180 Japanese carrier aircraft were shot down. The American force suffered heavily and was forced to withdraw. The aircraft carrier *Hornet* and a destroyer were sunk, and the carrier *Enterprise*, the new battleship *South Dakota*, a cruiser, and a destroyer were damaged; 74 American planes were also lost.

The last major naval battle off Guadalcanal consisted of a series of engagements during the period November 12-15, known as the Battle of

Guadalcanal. In three days of fighting the Japanese lost 2 battleships, 1 cruiser, 3 destroyers, and 11 transports sunk; 3 cruisers and 6 destroyers were damaged. In addition, thousands of ground troops drowned when the transports were sunk. American losses totaled 2 light cruisers and 7 destroyers sunk and 8 other vessels damaged. A damaged light cruiser was sunk by Japanese torpedoes while retiring. The final but lesser naval action was the Battle of Tassafaronga, fought in the narrow channel south of Savo Island on the night of November 30. An American force of 5 cruisers and 6 destroyers intercepted 8 Japanese destroyers carrying troop and equipment reinforcements. The smaller warships had the advantage in the constricted waters, and American radar was ineffective against targets close to shore. The Americans came off second best, losing 1 cruiser and suffering severe damage to 3 others. The Japanese lost only 1 destroyer, but the remainder turned about and failed to land their troops and cargo ashore.

The ground fighting continued sporadically after the abortive Japanese offensive of October 23-26. On the night of November 2-3, about 1,500 Japanese landed near Koli Point. By November 8, they had been encircled, and less than half of them escaped. American ground strength now grew rapidly. On November 4, the 8th Regiment of the 2d Marine Division disembarked; on November 12, 6,000 reinforcements, including the 182d Infantry Regiment of the Americal Division, arrived. Ground activity for the rest of the year was confined largely to constant pressure on the Japanese, and Marine Corps and Army troops advanced as far as Point Cruz.

The Japanese situation deteriorated rapidly after the costly defeat suffered in the naval Battle of Guadalcanal. Only small quantities of supplies and not more than 1,000 troop replacements were able to reach the island during the rest of the campaign. The food situation became desperate, and disease took an increasing toll. In January 1943, General Hyakutake departed with his headquarters for Bougainville, and other senior commanders began to desert their troops and head northward.

By this time, Maj. Gen. (later Lt. Gen.) Alexander M. Patch, now in command of the island garrison, had approximately 50,000 men. His principal tactical unit was the new 14th Corps, composed of two Army divisions, the Americal and the 25th, and the 2d Marine Division. Beginning on December 9, the 1st Marine Division had left for a well-merited rest. A general offensive was launched, and though the remaining Japanese fought bitterly, they were gradually forced westward into the point at Cape Esperance. The Tokyo Express now began operations in reverse, evacuating rather than strengthening the garrison. The Americans reached Cape Esperance on February 9, bringing the campaign to a close.

For the Japanese, Guadalcanal was a costly experience. In addition to many warships and hundreds of planes with their experienced pilots, they had lost 14,800 ground troops killed or listed as missing, 9,000 through sickness, and about 1,000 captured. Only 13,000 men were evacuated. American troop casualties totaled 1,600 killed and 4,245 wounded, of whom 1,042 killed and 2,894 wounded were Marines.

Papuan Campaign.—The offensive in New Guinea, which General MacArthur had been or-

dered to launch simultaneously with the Guadalcanal offensive, was to start from Port Moresby and was designed to drive the Japanese from the northeast coast of the island. A Japanese amphibious force sent to capture Port Moresby had been turned back in May 1942 in the Battle of the Coral Sea. Now the Japanese planned to seize the town by an overland advance.

On July 22, Maj. Gen. Tomitaro Horii landed 4,400 troops at Gona, on the northeast coast of Papua, and quickly occupied Buna. By July 28, elements had penetrated inland to Kokoda, high in the Owen Stanley Range, where they encountered Australian resistance. Additional men and supplies arrived on the coast, and a base was established in the Buna-Gona area. By August 22, more than 11,000 Japanese were ashore, and the drive on Port Moresby began in earnest. The Australians delayed the advance courageously, and by mid-September had halted it at a point less than 32 miles from Port Moresby. Meanwhile, in the last days of August, 2,000 Japanese had landed at Milne Bay, on the southeastern tip of Papua, in order to seize the airstrip there and advance along the coast to Port Moresby. The attempt was a complete failure. Australian troops killed more than 600 of the invaders; most of the rest were evacuated by destroyers, while a few made their way up the coast to Buna. The Japanese supply line over the difficult mountains, tenuous at best, was almost broken by relentless bombing and strafing attacks by Allied planes.

By the end of September, MacArthur had in Papua the Australian 7th Division, commanded by Maj. Gen. George A. Vasey, and the 126th and 128th Infantry regiments of the American 32d Division, commanded by Maj. Gen. Edwin F. Harding. He now ordered a counterattack against the half-starved Japanese. At this time the Japanese situation on Guadalcanal was critical, and just as MacArthur's offensive was launched, the forces operating against Port Moresby were recalled to Buna. Allied troops then converged on Buna, the Australians moving over the Kokoda Trail and the Americans overland, by air transport to improvised airfields at Wanigela and Pongani, and by small boats along the north shore. By November 18, the outposts of the Buna position had been reached. It was an exceedingly strong position, for the Japanese had taken every advantage of the swampy terrain and dense tropical vegetation. Three strong defenses, each almost completely hidden, had been constructed: one was in front of Buna and the airstrip to the southeast, another lay across the Soputa-Sanananda road, and the third was the village of Gona. The position at Buna, held by about 2,200 Japanese, was in the zone of the American 32d Division; the other two, with a total garrison of more than 3,000, were in the zone of the Australian 7th Division.

The battle was to be essentially a slugging match between ground forces. The United States Navy would not risk its ships in the uncharted waters off Buna. Allied planes could not identify targets in the dense undergrowth and dropped bombs on their own troops, causing some casualties and seriously affecting morale, which was already depressed by the swampy terrain, high humidity, and numerous jungle insects and blood-sucking leeches. An attack in the rain against Buna on November 19 failed; an all-out attack along the entire Buna front on

November 22 was equally fruitless. On the same day, the Australians, reinforced by two American battalions, launched a general attack against Gona and along the Soputa-Sanananda road. No headway was made, but American troops had begun to work their way around the Japanese position on the road, and by November 30 they had established a roadblock behind the Japanese, thereby cutting the supply line to Sanananda. The next three weeks were spent in maintaining this roadblock against desperate enemy attacks from all sides.

On December 1, Lt. Gen. Robert L. Eichelberger was summoned to revitalize the American front before Buna. He arrived in time to see the failure on December 2 of a major assault by the 32d Division, which depressed troop morale to probably its lowest point. After reorganization another general offensive was launched against the Buna position on December 5. It was generally unsuccessful, but one unit broke through the Japanese lines west of Buna and established a narrow corridor to the coast. Reinforcements arrived on December 15, and the village of Buna was captured. By December 17, an Australian brigade with tanks had arrived in the American sector, and an attack was made the next morning. Progress was slow but steady. By Jan. 2, 1943, the Buna position had been taken. All efforts were now directed toward Sanananda and Gona. By January 22, organized Japanese resistance had ceased, and the Papuan campaign came to an end. About 12,000 Japanese, 2,000 Australians, and 850 Americans died in this campaign.

Operations in 1943.—By the beginning of 1943, with their victories on Guadalcanal and in Papua, the Allies had definitely wrested the initiative from the Japanese in the South and Southwest Pacific areas. Since the preponderance of Allied resources in the Pacific theater were devoted to these operations, little could be done in the Central and North Pacific after the Battle of Midway. Admiral Nimitz' operations for the rest of 1942 had therefore been limited to submarine warfare and raids on Japanese island bases by air and light naval forces. In Burma, while awaiting reinforcements, the British were organizing their forces for limited land and amphibious operations to capture Akyab, and Lt. Gen. (later Gen.) Joseph W. Stilwell was working feverishly to organize Chinese divisions and train them into effective fighting units. An air transport system had been put into operation over the 500 miles of the Himalayan "hump" to move supplies into China, and construction had begun on a new road to replace the portion of the Burma Road in Japanese hands.

In the South and Southwest Pacific the Allies continued their offensives up the chain of the Solomons and along the north coast of New Guinea. General Hyakutake's Seventeenth Army, with headquarters on Bougainville, defended the Solomons, while Lt. Gen. Hatazo Adachi's newly activated Eighteenth Army, with headquarters in the Lae-Salamaua area, controlled operations in eastern New Guinea. Both armies operated under the direction of Gen. Hitoshi Imamura's Eighth Area Army, with headquarters at Rabaul. In early February 1943, the headquarters of the American Sixth Army was activated at Brisbane, Australia, with Lt. Gen. (later Gen.) Walter Krueger in command. Most of the American troops in the Southwest Pacific, including the 1st Marine Division, the 32d and 41st Army divi-

sions, the 503d Parachute Infantry Regiment, the 158th Infantry Regiment, and certain artillery and engineer organizations, were immediately assigned to this army. Soon it was to become the spearhead of General MacArthur's strategic offensive to recapture the Philippines. Adm. (later Admiral of the Fleet) William F. Halsey now commanded the South Pacific area. Ground operations in his area were to be conducted by the 14th Corps, under the command of Maj. Gen. (later Lt. Gen.) Oscar W. Griswold, which consisted of the 25th, 37th, 43d, and Americal divisions.

A detailed account of the many subsequent operations in the Solomons and along the northern New Guinea coast, which required almost all of the year 1943 to accomplish, is beyond the scope of this article. Many islands were captured, and numerous coastal leapfrog operations were conducted to isolate Japanese garrisons. These are indicated on Map 40. The importance of these operations should not, however, be depreciated: most of the positions were bitterly contested, Japanese power was severely drained, and American forces developed a skill in amphibious operations that was to serve them well in later major operations.

Approach to the Philippines.—As 1944 dawned, Allied advances in the Solomons and New Guinea had virtually isolated the Japanese base at Rabaul; it appeared that the dreaded assault on this strongly fortified position would not be necessary. Toward the end of 1943, tremendous gains in aircraft and naval construction in the United States had permitted the Allies to take the offensive on a large scale. In November, Admiral Nimitz' Central Pacific forces had assaulted and captured Tarawa and Makin in the Gilbert Islands, obtaining bases that could support operations against the next objective, the Marshall Islands, and from which land-based planes could pound the great Japanese base at Truk. In China during 1943, air attacks had constituted the only Allied offensive operations. With increased strength, bombers operating from Chinese bases attacked Japanese bases in Burma, Thailand, Indochina, Hainan, Hong Kong, and Taiwan. Japanese shipping along the China coast was frequently attacked with good results. In Burma seesaw ground operations between Japanese and British-Chinese troops had taken place without material advantage to either side. There also the Allies gradually came to control the air.

During 1944 the tempo of the war in both the Southwest and the Central Pacific areas accelerated with each passing month. General MacArthur projected an advance to the Philippines along the New Guinea axis, while Admiral Nimitz moved directly westward. MacArthur's plan was to take advantage of the position of the Japanese forces, separated as they were by long distances and with only sea and air communications connecting them. The island-hopping and leapfrog techniques, which had proved so successful in 1943, were well suited to the isolation or destruction of the Japanese posts ahead. By these means, General Krueger's Sixth Army was to advance more than 2,000 miles to the Philippines in the next six months. With units of the Australian First Army in the process of taking over operations in eastern New Guinea and the Solomons and blocking the Japanese at Rabaul, MacArthur had adequate troops for the contemplated operations, but he was weak in naval and

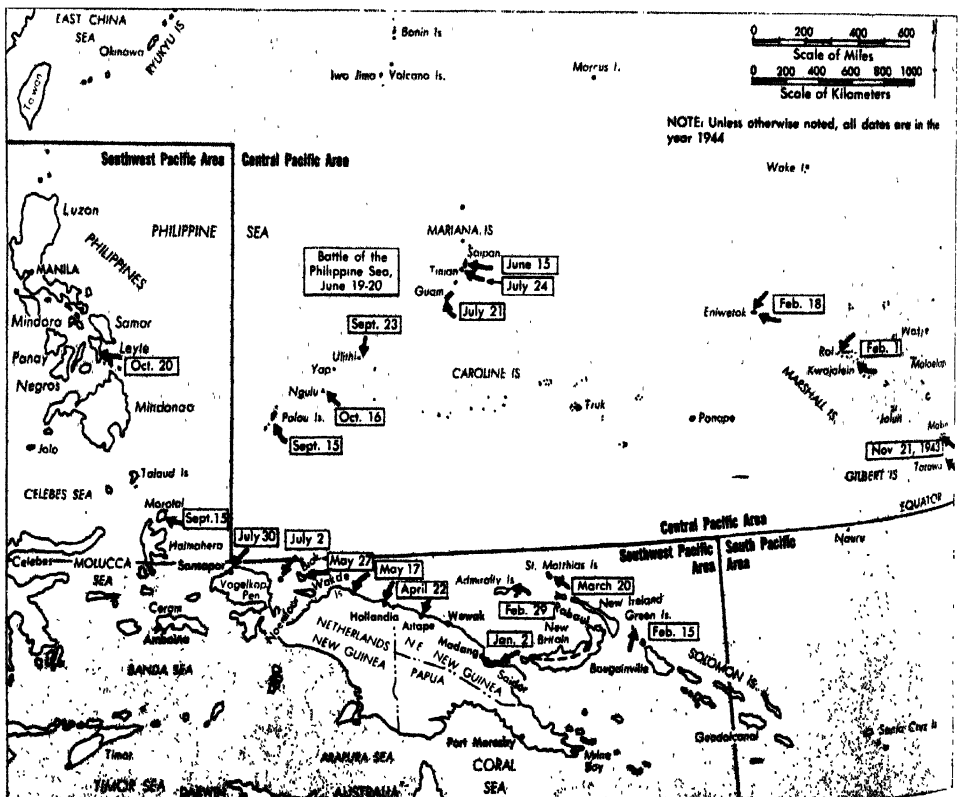

air support, particularly carrier aircraft to assist his long jumps up the New Guinea coast. Arrangements were made with Admiral Nimitz to have Rear Adm. (later Adm.) Marc A. Mitscher's Task Force 58, a large fleet strong in carriers, support MacArthur. Successive operations in both the Southwest and Central Pacific areas are shown on Map 41. By mid-September 1944, American forces were landing on Morotai Island and the Palau Islands. At the same time, Admiral Halsey's Third Fleet was launching its many carrier aircraft in attacks on Mindanao and other enemy bases in the Philippines.

Return to the Philippines: Leyte Campaign.—It had been the American plan to capture the outlying islands of Mindanao, Talaud, and Yap and then to invade Leyte, in the central Philippines, on Dec. 20, 1944. Indeed, Maj. Gen. (later Gen.) John R. Hodge's 24th Corps had left Hawaii on September 15 en route to Yap. On that day, Admiral Halsey reported extremely weak opposition to his carrier-air attacks in the central Philippines and recommended the abandonment of the preliminary operations and an early attack directly on Leyte. It was decided to carry out his recommendation, and the 3d Amphibious Force, carrying Hodge's troops, changed course for MacArthur's area to participate in the Leyte operations, which were rescheduled for October 20.

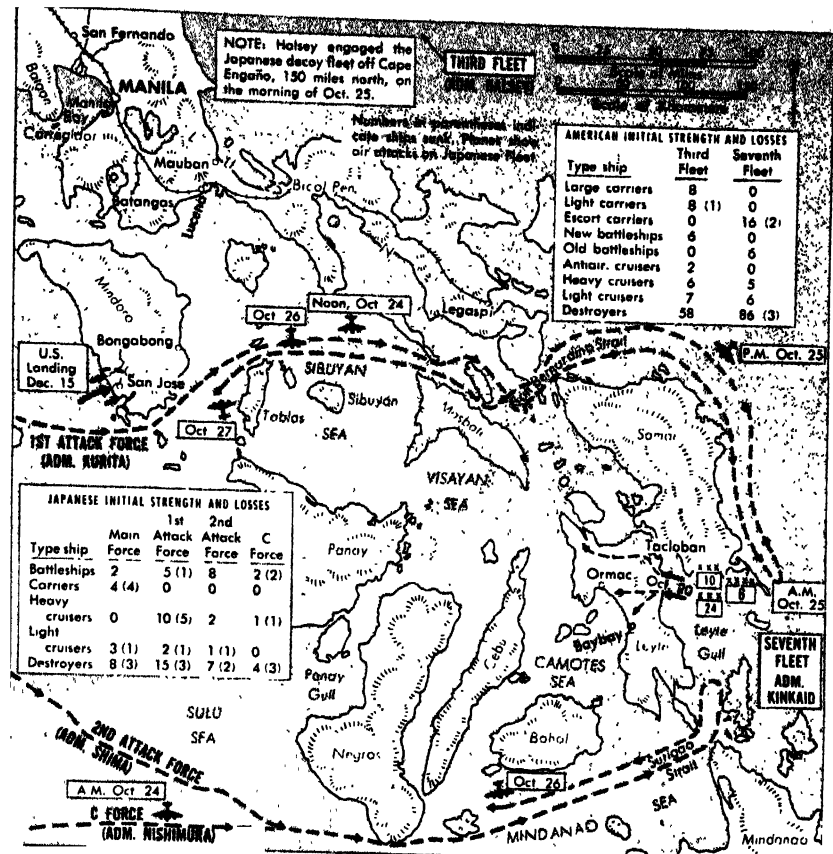

An expedition comprising more than 700 ships was assembled for the invasion. Vice Adm. Thomas C. Kincaid's greatly augmented Seventh Fleet provided the naval and carrier-air support, it was divided into Northern and Southern Attack forces. General Krueger commanded the ground troops: the 10th Corps, Maj. Gen. Franklin C. Sibert commanding, accompanied the Northern Attack Force; General Hodge's 24th Corps, the Southern Attack Force. On October 10, the Third Fleet inaugurated a seven-day air attack against Japanese bases in the Ryukyu Islands, Taiwan, and Luzon to protect the northern flank of the invasion forces. More than 100 Superfortresses of the 20th Bomber Command in China joined in the attack on Taiwan. The Third Fleet did its job of protection well, and MacArthur's forces arrived off Leyte without incident.

The defense of the northern Philippines had been entrusted to Gen. Tomoyuki Yamashita, conqueror of Singapore in 1942, and his Fourteenth Area Army. The Thirty-fifth Army, under Lt. Gen. Sosaku Suzuki with headquarters on Cebu, was charged with the defense of the central and southern Philippines. On October 20, there were 270,000 Japanese ground and air troops in the Philippine Islands. Suzuki expected that Mindanao would be the first American objective in the Philippines; hence only his 16th Division occupied Leyte. Its combat strength

Map 41. APPROACH TO THE PHILIPPINES (Nov. 21, 1943–Oct. 20, 1944). After the successful operations in eastern New Guinea and the Solomon Islands, the American forces began a two-pronged advance toward the Philippines. Adm. Chester W. Nimitz' Central Pacific forces drove straight westward; Gen. Douglas MacArthur's Southwest Pacific forces leaptfrogged along the northern New Guinea coast. Many Japanese garrisons were isolated and left to wither on the vine. These step-by-step advances are shown on the map. The first landings in the Philippines were made on Leyte Island by MacArthur's troops on Oct. 20, 1944.

Map 42. RETURN TO THE PHILIPPINES: LEYTE CAMPAIGN (Oct. 20, 1944-Jan. 1, 1945). The American Sixth Army landings on Leyte on Oct. 20, 1944, surprised the Japanese and met little opposition. As at Guadalcanal, however, the Japanese poured all reinforcements available into the defense of Leyte. The ground action was particularly bitter during November, but the Sixth Army gradually forced Lt. Gen. Sosaku Suzuki's troops back with appalling losses. The fighting gradually tapered off, and by Jan. 1, 1945, the American troops were in full control of the island. Early in the campaign the United States ground forces were threatened with isolation when Japanese naval forces converged on Leyte Gulf, as shown. Vice Adm. Takeo Kurita's sudden decision to turn around and withdraw probably saved the United States forces from disaster.

was 10,620 men, and it was supported by 1,000 base defense troops and 10,000 service troops. The division was no match for the four American divisions that landed on October 20, and the surprised Japanese troops withdrew to the north-western section of Leyte.

While the Japanese were caught unprepared on the ground, this was not true of the Japanese Navy. The Combined Fleet went into action with a prearranged plan that almost turned the invasion into an American disaster. The Battle for Leyte Gulf, which took place on October 23–26,

was actually a series of major surface and air engagements, culminating in three almost simultaneous naval actions: the Battle of Surigao Strait, the Battle off Samar, and the Battle off Cape Engaño. These complex operations can best be understood by consulting Map 42. The Japanese plan was to destroy the American landing forces and supporting ships at Leyte Gulf by converging naval attacks from the north and south. The powerful Second Fleet, under Vice Adm. Takeo Kurita, was to make the converging attacks with its two subdivisions, the 1st Attack

In October 1944, Gen. Douglas MacArthur (left), with his chief of staff, Lt. Gen. Richard K. Sutherland at his side, returns to the Philippines to direct the successful invasion of Leyte.

Wide World

Force from the north and C Force from the south. These forces were to destroy the American warships at Leyte Gulf. Vice Adm. Kiyohida Shima's 2d Attack Force (Fifth Fleet) was to follow C Force and destroy American shipping in the gulf after the warships had been eliminated. Vice Adm. Jisaburo Ozawa's Third Fleet, with 4 half-empty carriers, was to move southward from Japan to lure Admiral Halsey's superior Third Fleet from the scene of action. If it succeeded in doing so and the major American forces at Leyte were destroyed, the loss of the entire Japanese Third Fleet would have been warranted.

On October 25, C Force entered Surigao Strait from the west and was attacked by the battleships and cruisers of Admiral Kincaid's Seventh Fleet. It was virtually destroyed. The 2d Attack Force came up in the rear, engaged the Americans briefly, and then reversed course and withdrew hastily under air attack. Meanwhile, Admiral Kurita's 1st Attack Force moved through San Bernardino Strait unmolested and headed southward for Leyte. (Admiral Halsey had moved to the north to engage the decoy Third Fleet; hence the strait had been left unguarded except for land-based aircraft.) Suddenly Kurita's warships appeared before Kincaid's unprotected escort carriers and destroyers off Samar. Guns from his battleships, up to 18 inches in caliber, fired at the carriers as they attempted to escape to the southeast. It began to look as though Kurita would have a turkey shoot among the huge assemblage of cargo and transport vessels in the gulf. Then, for many reasons (none particularly valid), he turned about and retired back through San Bernardino Strait. En route his fleet was attacked and damaged by a detachment of fast battleships and carriers sent southward by Halsey. The latter had concentrated his attention on Ozawa's carriers and had succeeded in sinking all of them.

The Japanese had planned to make the main defense of the Philippines on Luzon. Now they decided to fight the decisive battle on Leyte. Reinforcements began to pour in by barge, destroyer, and transport. The 16th Division was joined eventually by five others: the 8th, 26th, 30th, and 102d divisions from other islands of the Philippines; and the crack 1st Division from the general reserve in Shanghai. Despite the loss of 1,200 planes to Halsey's Third Fleet over the air replacement route from the Ryukyu Islands to the Philippines and the destruction of more than 400 planes at the Manila airfield complex, the Japanese managed to bring in 1,000 additional aircraft. Troop reinforcement convoys were under constant attack by American planes, and thousands of troops en route to Leyte were sent to watery graves.

The crucial land fighting occurred during November. Additional American troops had been rushed to Leyte, and Krueger's Sixth Army had been increased to seven divisions. The 10th Corps, operating in the northern sector, consisted of the 24th and 32d Infantry divisions and the 1st Cavalry Division; the 24th Corps, in the southern sector, of the 7th, 77th, and 96th Infantry divisions and the 11th Airborne Division. The fighting was extremely bitter, but the Japanese were gradually forced back. On December 6-7, they made a final bid for victory with a counterattack and paratroop operations designed to capture the Burauen airfields, but were un-

successful. By Jan. 1, 1945, the Leyte campaign could be regarded as closed except for minor mopping-up operations. Meanwhile, on December 15, American troops had landed on Mindoro, just south of Luzon, to set up a base for operations against that island.

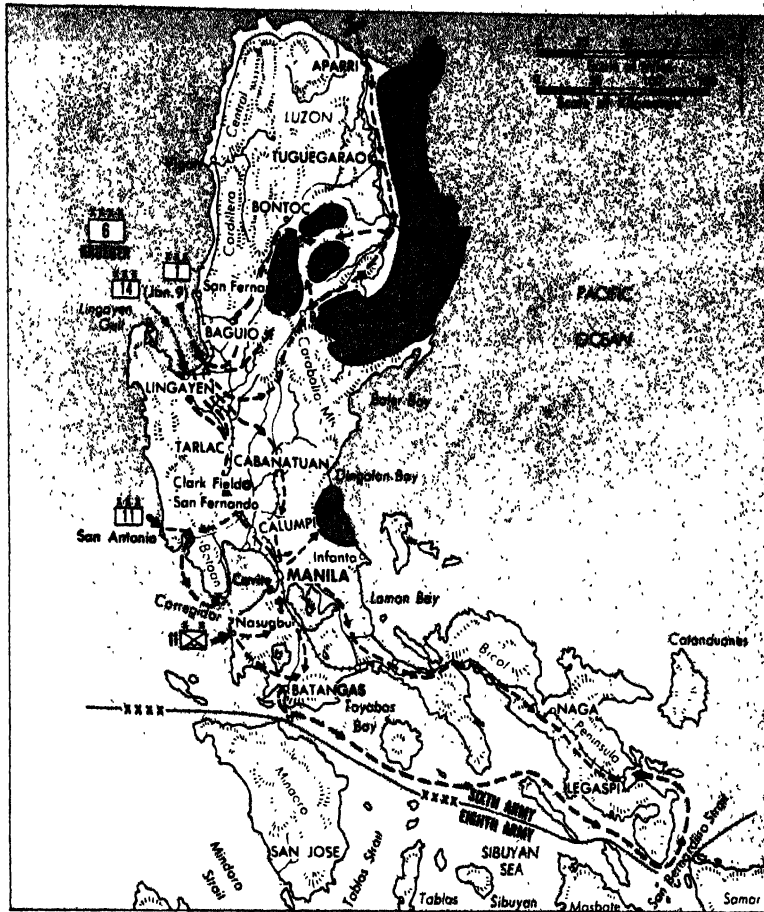

The Japanese had committed the major portions of their air and naval forces to the defense of Leyte. Both had suffered staggering losses. Their ground forces incurred about 70,000 casualties; American ground force casualties totaled 15,584.

Liberation of the Philippines.—During 1944 the Allies had registered major gains on all fronts except in China. There the Japanese had resumed offensive operations on a large scale, exerting every effort to make their forces in China self-sufficient. In Burma an Allied advance had cleared the route of the new Ledo Road, connecting with the Burma Road in China, and in January 1945, supplies began to move over the road into China. The British, having repulsed a major Japanese offensive earlier in the year, were now themselves on the offensive and driving toward Rangoon and Mandalay. In the Pacific the two-pronged advance of Admiral Nimitz and General MacArthur had merged in the Philippines, the outer defenses of Japan had been ruptured by the seizure of the Marianas, and Tokyo had come within range of American Superfortresses. Moreover, by the end of 1944, American submarines alone had sunk 4,300,000 tons of Japan's merchant shipping, and the Japanese were hard pressed to support their needs at home. As the year 1945 began, it was apparent that Japan had lost the war, but she would not yet admit defeat. Her forces continued to struggle with the same fanatical zeal and tenacity of purpose that had characterized their fighting in the early days of the war. While her air, ground and naval strength had been considerably reduced, strong forces for defense still remained at her disposal.

The date set for the invasion of Luzon was Jan. 9, 1945. General Krueger's Sixth Army was to conduct the operations; General Eichelberger's Eighth Army took over Leyte, Samar, and Mindoro and prepared to clear the Japanese from the islands south of Luzon. The Australian First Army was assigned the mission of eliminating isolated Japanese garrisons on New Guinea, New Britain, and Bougainville and of recapturing Borneo and its rich oilfields. The Sixth Army planned to land at Lingayen Gulf, secure the central plain of Luzon, and capture Manila. Naval and air elements would conduct demonstrations along the south coast, and guerrillas would destroy communications in southern Luzon. Admiral Kincaid's augmented Seventh Fleet, designated the Luzon Attack Force, had the mission of transporting, landing, protecting, and supporting the invasion forces. It consisted of more than 850 vessels, including 6 old battleships, 18 escort aircraft carriers, 10 cruisers, 141 destroyers, and a host of smaller craft. Admiral Halsey's roving Third Fleet was to cover the invasion force by air strikes against targets on Taiwan and northern Luzon. Lt. Gen. (later Gen.) George C. Kenney's Far East Air Forces, based on Leyte and Mindoro, would bomb targets on Luzon, and China-based Superfortresses were to hit Taiwan and targets along the China coast.

For the Lingayen Gulf landing the Sixth

Map 43. LIBERATION OF THE PHILIPPINES (Jan. 9–Aug. 14, 1945). Unsupported by the Japanese Navy and having expended practically all of his air force and many of his best troops in the futile defense of Leyte, Gen. Tomoyuki Yamashita realized that he could not defeat a determined attack on Luzon. He planned to offer what resistance he could, and then withdraw into the mountains to hold out as long as possible. The American landings were not strongly opposed, but the defense of Manila was fierce. Yamashita's Fourteenth Area Army was eventually forced into the mountains and broken into the five isolated groups shown. His troops surrendered after Japan capitulated on August 14. In the meantime, Lt. Gen. Robert L. Eichelberger's Eighth Army was cleaning up Japanese resistance on Mindanao and the other southern and central islands of the Philippines. He had his opponents similarly boxed in in the mountain areas when the war ended.

Army had Maj. Gen. (later Lt. Gen.) Oscar W. Griswold's 14th Corps (37th and 40th divisions); Maj. Gen. Innis P. Swift's 1st Corps (6th and 43d divisions); and a reserve that included the 25th Division, the 158th Regimental Combat Team, the 6th Ranger Battalion, and the 13th Armored Group. In view of the reports of great Japanese strength on Luzon, additional troops were scheduled to join Krueger later. These were the 32d, 33d, and 41st divisions, the 1st Cavalry Division, and the 112th Cavalry Regimental Combat Team.

General Yamashita's Fourteenth Area Army on Luzon aggregated approximately 250,000 men. There were only about 150 Japanese aircraft based on the island, but they were to exact a frightful toll of American shipping by suicide attacks known as Kamikaze (q.v.). These attacks began on January 4 as the American invasion fleet passed the island of Panay. By January 13, when the last of the Japanese planes had been expended, 17 American ships had been sunk, 20 had sustained major damage, and 30 had received lesser damage. Isolated and lacking air and naval support, Yamashita entertained little hope of holding Luzon, and he planned only to conduct a delaying action to prevent the fall of the island as long as possible. His forces were divided into three groups: the Shobu Group (140,000 men) in the north, to guard against an invasion through Lingayen Gulf; the Kembu Group (30,000) in the center, to protect the

Clark Field airfield complex; and the Shimbu Group (80,000), to protect southern Luzon. When forced to do so, the Japanese would withdraw into the mountains in the east and hold out there to the end.

At 9:30 A.M. on January 9, the Sixth Army landed at Lingayen Gulf with the 14th Corps on

Wide World

the right and the 1st Corps on the left. Only light opposition was met, and by nightfall 68,000 men were ashore. While the 14th Corps made steady progress toward Clark Field, the 1st Corps encountered bitter resistance in the Cabaruan Hills, directly in its path, and in the Caraballo Mountains, on its eastern flank. The Japanese there were a threat to the American line of communications, for Lingayen Gulf would have to serve as the supply base until Manila had been captured. By January 31, the 14th Corps had seized the airfield complex in the Clark Field-Fort Stotsenburg area, but the 1st Corps was still occupied in the Caraballo Mountains. In the meantime, two subsidiary operations by Eighth Army troops had taken place. On January 29, the 11th Corps landed near San Antonio and rushed inland to seal off the Bataan Peninsula; on January 31, the 11th Airborne Division landed at Nasugbu and headed for Manila.

Krueger now organized elements of the 14th Corps into flying columns for a dash on the capital. By February 3, American troops had reached the outskirts of Manila, but it would take a month of stern fighting before the city could be cleared. Although Yamashita offered stubborn resistance in the mountains, he was pushed back steadily. By March 15, his forces had been broken into three separate groups, but he held out until Japan surrendered on August 14.

Meanwhile, Gen. Eichelberger's Eighth Army methodically set about eliminating Japanese resistance in the central and southern islands. By August 14, the greater part of the organized resistance had been wiped out, and the main Japanese forces on Mindanao were deep in the mountains of the interior, where they faced starvation. The Japanese lost more than 170,000 known killed on Luzon; American casualties were approximately 38,000, including about 8,000 killed.

Collapse of Japan.—Even as American forces were fighting in the Philippines, on Iwo Jima, and on Okinawa, preparations were being made for the invasion of the Japanese homeland. The Japanese surrender on August 14 fortunately made it unnecessary to conduct this admittedly hazardous and costly undertaking.

The final phases of the war are described in sections 10. *War in the Central and Northern Pacific* and 11. *War in Eastern Asia*. See also

10. War in the Central and Northern Pacific

Navies of Japan and the United States.—A maritime war necessarily followed the breakdown in December 1941 of peaceful relations between the United States and Japan (see section 14 *Diplomatic History*). Poor in resources, Japan required the mineral wealth of the Dutch and British possessions to the south if she were to achieve her national aim, the domination of East Asia. To check Japan the United States had to project her power 6,000 miles across the Pacific Ocean. After initiating the conflict, Japan moved so far so rapidly that she soon accomplished her goals and threatened Australia. The axis of movement of United States forces during the first two years of the Pacific war therefore had to be directed to the southwest rather than to the west, as had been planned. Thrown on the defensive by the attack on Pearl Harbor, the United States Navy was barely able to protect the vital line of sea communications to Australia. When the offensive phase finally began for the United States, that nation found itself with the choice of two campaigns, one across the Central Pacific and the other from the South Pacific back along the route that the Japanese had taken. Whatever the choice, all major movements would be made overwater. Command of the sea was essential, and the nation whose navy gained control of the waters of the Western Pacific would be victorious.

The size of the two navies that would be the determinants in the Pacific struggle had been set at the Washington Conference of 1921–1922. For Japan a war in the Pacific would probably be fought against the United States, with its aim being a negotiated peace that would leave Japan a free hand in East Asia. This could be achieved by a strategic defense with a navy two thirds as large as that of the United States. The size assigned to Japan by the Washington Con-

ference was 60 percent, which Japanese officers claimed was not sufficient. They therefore built ships superior to those of the United States in fire-power and speed at the expense of livability and radius of action. Japan's two largest battleships, the *Yamato* and the *Musashi*, each mounted nine 18-inch guns; she possessed a greater number of aircraft carriers than did the United States; aircraft, torpedoes, and equipment for night fighting were superior; and ship's companies were superbly trained. Tactical plans called for the enemy to be reduced by attrition and then destroyed in a major fleet action.

The United States Navy entered the war weak in some elements and strong in others. Ordnance was inferior, but its system of high-pressure steam propulsion was the best in the world. Its Marine Corps had the potential to seize the bases needed, and its train of auxiliaries, which for two decades had supported the fleet while at anchor in the San Pedro-San Diego area of California, became the nucleus for the mobile type of support that would characterize sea, air, and ground operations in the Pacific.

Merchant shipping would be the major weakness of both nations. The United States did not require a large merchant marine in peace and thus had to build one in war. The Japanese possessed a sizable merchant fleet, but it was forced to do a double job: bring in food and raw materials for a war economy and support military operations overseas.

When the war started, the United States had 17 battleships, 6 aircraft carriers, and 32 cruisers, distributed about equally between the Atlantic and the Pacific. The Japanese had 10 battleships, 9 aircraft carriers, and 46 cruisers, all stationed in the Western Pacific. Numbers of other types of warships were in approximately the same proportions.

The officers of the Japanese Navy were dedicated to their profession, and they drove themselves and their men hard. Training was tough and realistic, and loss of life was accepted as it would be in war. Although admiring the United States and personally friendly toward its Navy, they thoroughly studied this prospective enemy. English was their second tongue, and the most promising officers were sent on attaché duty to Washington. The officers and men of the United States Navy reflected the merits and faults of their countrymen. They were unique, however, in a way of life that combined devotion to duty with a spartan ability to live continually in their warships. Their major weakness in 1941, a grave one indeed, was a lack of appreciation of the strength of their probable enemy. Because of this, many United States sailors would die, and all would suffer a humiliation especially bitter to the proud.

In support of the national policy, Japanese naval planning provided for a quick seizure of Dutch and British possessions in Southeast Asia. The United States was to be held off by a chain of island defenses across the Western Pacific. For this purpose the Kuril, Mariana, and Caroline islands were already in Japanese hands, but the islands on the southern end of the chain, mandated to Australia and New Zealand, would have to be seized.

United States war planning had to provide for the defense or recapture of the Philippines with a step-by-step movement across the Pacific. Naval officers realized the dangerously exposed position

of the United States in the Far East, and they rankled under the provision of the Washington Conference that forbade the development of bases in American Far Eastern possessions. United States war plans were sound in principle but weak in detail. They were not supported by adequate intelligence, their timing schedule was too optimistic, and logistics were neglected. The last-named deficiency was revealed when the fleet was based on Pearl Harbor in 1940, and an overseas supply activity had to be established at Oakland, Calif.

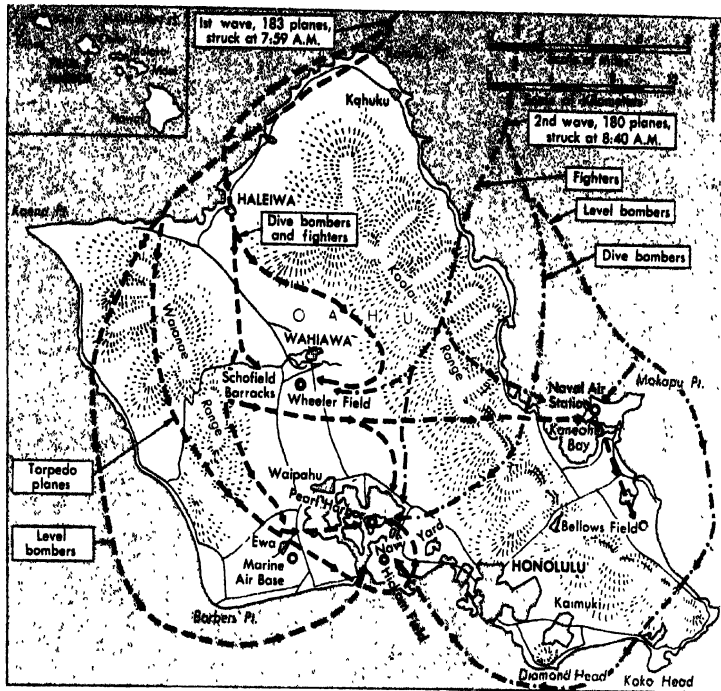

Pearl Harbor.—The oil of Borneo and Sumatra 5,000 miles away, brought about the attack on Pearl Harbor. In July 1940, the United States placed an embargo on the export of oil and scrap metal without a special license and of all aviation gasoline to Japan. When Japanese forces moved into northern French Indochina in September, the United States reacted with an embargo on scrap iron and steel, and when they also moved into southern Indochina, in July 1941, all Japanese assets in the United States were frozen. Similar action by Great Britain and the Netherlands affected shipments of oil from the East Indies. This created such a critical situation for Japan that its cabinet decided that, unless the United States made concessions, the oilfields to the south would be seized by military operations.

The plan of the Japanese Navy's General Staff was to employ the navy's entire air and surface strength in a direct thrust southward, quickly secure its objectives, and then turn its attention to the Western Pacific, where an advancing United States Fleet would be dealt with as the Russians had been at Tsushima in 1905. Adm. Isoroku Yamamoto, commanding the Japanese Combined Fleet, had a different plan. He believed that the United States Pacific Fleet would have to be destroyed in the first year of the war before it could be strengthened by the building program then in progress. His plan called for a carrier air attack on this fleet at its base in Pearl Harbor as the opening act of the war, while the advance to the south would be supported primarily by land-based aircraft. When a test of the plan on a game board predicted heavy losses, the Navy General Staff opposed it, but the popular Yamamoto forced its acquiescence by a threat of resignation.

A force composed of Japan's 6 largest carriers, 2 fast battleships, 2 cruisers, and a number of destroyers and tankers, commanded by Vice Adm. Chuichi Nagumo, was assigned this task. The carriers' air groups received special training. Aircraft torpedoes were equipped with ailerons to enable them to be used in the shallow depth of Pearl Harbor, and fins were fitted to armor-piercing shells to convert them to bombs.

The task force assembled in secrecy at Takan (now Hitokappu) Bay on Etorofu-to (now Iturup Island) in the Kurils and departed for its mission on November 26¹, proceeding eastward in northern latitudes. It observed radio silence, and no shipping was encountered. The passage was rough, and destroyers had to be sent back, but carriers, battleships, and cruisers reached the launching point about 200 miles north of the Hawaiian Islands at 6 A.M. on December 7. Earlier a force of 16 fleet-type submarines had been deployed off Pearl Harbor, where 5 of them launched midget submarines. Two of the midgets succeeded in getting inside Pearl Harbor on December 7,

¹ Dates in all cases are those of the area in which events occurred.

Map 44. JAPANESE ATTACK ON PEARL HARBOR (Dec. 7, 1941). In a military sense the Japanese attack on Pearl Harbor was well conceived and brilliantly executed. It put the United States Pacific Fleet out of action long enough to permit attainment of the primary objective, conquest of the Southern Regions. But the Japanese were content with half a victory. They failed to destroy the vulnerable maintenance facilities and oil storage or to assault and occupy the Hawaiian Islands, both of which courses were feasible. These derelictions were to allow the United States Navy to recover and enter the fray much sooner than the Japanese expected.

but were sunk. One grounded on the north coast of Oahu, and its two-man crew was captured; the others did not return to the recovery area. This entire submarine effort accomplished nothing.

The warships of the Pacific Fleet at Pearl Harbor on the morning of December 7 included 8 battleships, 9 cruisers, 29 destroyers, 5 submarines, and a number of auxiliaries. One fourth of their anti-aircraft batteries were manned. Fortunately for the United States, no carriers were present. The *Saratoga* was still being overhauled on the west coast, while the *Lexington* and the *Enterprise* with their task forces were at sea ferrying aircraft to Wake and Midway Islands.

The first wave of attacking Japanese aircraft, launched at 6 A.M., was composed of 183 dive bombers, level bombers, torpedo planes, and fighters. This group encountered no search aircraft in its two-hour approach and was barely sighted before the first bombs were dropped. It was detected by a United States Army radar operator, but the officer whom he informed decided that the aircraft were friendly. The attack began at 7:59 A.M. with dive bombing on the airfields. Torpedo planes then attacked the 7 battleships moored to concrete quays on the northwest side of Ford Island in Pearl Harbor. Heavy bombers followed. Only 4 United States aircraft got off the ground, and these were soon shot down. Japanese fighters, having no opposition, strafed the closely packed Army Air Forces (AAF) planes, which had been lined up for easier protection against sabotage, the supposedly major threat. The second wave of 180 aircraft struck at 8:40 A.M. Its pattern of attack was similar to that of the first wave, except that it launched no torpedo planes.

By this time the ships' anti-aircraft batteries were firing, and these brought down the only Japanese aircraft lost by gunfire. The attack was over by 9:15 A.M., and before 1 P.M. all surviving Japanese aircraft had returned to their carriers.

Only 29 planes, with their crews of 55 officers and men, were missing. Of the American battleships, the *Arizona* was completely destroyed, the *California* and *West Virginia* were sunk, the *Oklahoma* capsized, the *Nevada* was heavily damaged, and the *Pennsylvania*, *Tennessee*, and *Maryland* were damaged but able to proceed under their own power to the west coast. In addition, 3 cruisers were damaged, 2 destroyers burned and heavily damaged, and 2 auxiliaries sunk and 2 damaged. Personnel casualties were heavy, 2,403 men losing their lives in the first hour of the war.

More words have been written about the Pearl Harbor disaster than perhaps about any other single event in United States history. The official investigations alone fill 39 volumes. Nevertheless Americans continue to ask "Why?" An answer is found in Roberta Wohlstetter's *Pearl Harbor. Warning and Decision* (Stanford, Calif., 1962). Contributing causes were invalid assumptions, faulty appraisal and dissemination of intelligence, and inadequate security measures. Behind these was a lack of war-mindedness at this Pacific base halfway around the world from areas where momentous events were happening. Adm. Husband E. Kimmel, the Pacific Fleet commander, admits to it: "We did not know that in the Atlantic a state of undeclared war existed" (*Admiral Kimmel's Story*, p. 2, New York 1955). The War and Navy departments also shared in responsibility for the disaster, not only by withholding intelligence but by assigning low priorities to critical equipment for ships and units in the Hawaiian area.

For Americans, Pearl Harbor was a disgraceful tragedy. For Japan it was a brilliant tactical victory, a temporary strategic success, a lost opportunity, and, in the end, a colossal political mistake. By sinking the battleships but not the carriers, the Japanese Navy resolved a long-standing argument among United States naval officers as to which type would comprise their capital ships. The

American people were aroused as they would not have been had the plan of the Japanese Navy's General Staff been adopted. The lost opportunity was Nagumo's failure to destroy with a second strike the Pearl Harbor base facilities, especially the exposed and fragile tanks that contained 4,500,000 barrels of precious oil. The destruction of these tanks would have sent the Pacific Fleet back to the west coast, might have starved Hawaii, and would certainly have broken the line of sea communications to Australia. Instead a prostrate United States Navy was allowed to recover at Pearl Harbor.

Battle of Midway.—Within hours after the Pearl Harbor attack the Japanese struck at the Philippines and Malaya, and for the next five months success followed success. By splendid preparation and planning the Japanese armed forces achieved their initial goals so quickly that they soon were confronted with the problem of what to do next. The offensive had to be retained, and the choice made was an advance toward Australia. Since the Japanese Army, with an eye on a weakened Soviet Union, would not release sufficient troops for an invasion of Australia itself, the plan was to occupy New Guinea, New Caledonia, and Fiji. This South Pacific advance was getting started when the Doolittle raid took place.

On April 18, 1942, 16 specially equipped B-25 AAF Bombers under Lt. Col. (later Lt. Gen.) James H. Doolittle took off from the carrier *Hornet*, 650 miles east of the Japanese islands, and made a raid on Tokyo. Most of the planes reached safety in China. Results were meager, but the Japanese believed that these aircraft had come from Midway. This atoll and the western Aleutians remaining in United States hands thus constituted a threat to the homeland, and the line of Japanese-held bases would have to be extended to include them. Yamamoto had always favored a campaign to the east, and he hoped by such a movement to bring out the remainder of the United States Pacific Fleet to battle. After his success at Pearl Harbor, the Navy General Staff could refuse him nothing, and despite the southern advance an order to capture Midway and occupy the Aleutians was issued on May 5. A force of 5 carriers and 11 battleships with 5,000 troops was to strike Midway on June 4, while another force (which included 2 carriers) was to support the Aleutian occupation. A submarine line was to form west of the Hawaiian group on June 1 to report any approaching United States forces.

Yamamoto believed that 2 United States carriers instead of 1 had been lost in the Battle of the Coral Sea on May 8, and he assumed that the 2 others were still in the South Pacific. He did not know that Adm. (later Admiral of the Fleet) Chester W. Nimitz, who had relieved Kimmel, was reading his messages. The 3 United States carriers were recalled, the damaged *Yorktown* was quickly repaired, and by June 1 all of them were at sea beyond the Japanese submarine line. Rear Adm. (later Adm.) Raymond A. Spruance commanded the *Enterprise* and *Hornet* group. Rear Adm. (later Adm.) Frank J. Fletcher with the *Yorktown* group was in tactical command, but Nimitz at Pearl Harbor retained over-all control.

On June 3, the Japanese carriers with the Aleutian force struck Dutch Harbor on Amaknak Island, and landings were made on Kiska

and Attu on June 6-7. A cruiser-destroyer-submarine force sent by Nimitz to check this strike never made contact with the Japanese.

The Japanese Midway force remained undetected until June 3, and its carrier group, which included the large carriers *Akagi*, *Kaga*, *Soryu*, and *Hiryu* and was still commanded by Nagumo, reached the launching point 240 miles northeast of Midway, at 4:30 A.M. on June 4. The first wave, composed of 108 planes, was reported by a United States patrol plane at 5:45 A.M. At 6:30 A.M., it struck Midway. Damage was heavy, but the group commander reported that another strike would be necessary. The second wave had been readied for a carrier attack if any United States carriers were discovered. Nagumo had sent out only a 7-plane search that morning. Hearing nothing from it by 7:15 A.M., he ordered the planes of the second wave to the hangar decks, where torpedoes would be exchanged for bombs while the first wave was being recovered. At 7:23 A.M., a cruiser plane reported American ships and, at 8:20 A.M., announced that one of them was a carrier. Nagumo decided to recover his planes first and then launch a heavy strike against the carrier at 10:30 A.M. The carrier sighted was the *Yorktown*; the faulty morning search left the *Enterprise* and the *Hornet* undiscovered by the Japanese all day.

The American commanders had the reports of the patrol plane and the attack on Midway. Since the *Yorktown* was still recovering the planes of her morning search, Fletcher sent the other two carriers toward the enemy. Spruance decided to close in for an hour to bring the enemy well within his combat range and perhaps to catch him refueling. At 7:30 A.M., Spruance launched his planes, and the *Yorktown* air group followed at 8:30 A.M. The

Map 45. BATTLE OF MIDWAY (June 3-6, 1942). The arrowheads show the locations of the elements of the United States and Japanese navies at midnight on June 3-4, the eve of the Battle of Midway. The Japanese forces (A-H) were as follows: A—main carrier force; B—main battleship forces; C and D—covering groups for the Midway occupation group (E); and the forces engaged in the Aleutians (F—second carrier force, G—Kiska occupation force, and H—Attu occupation force). These forces aggregated 4 large carriers, 4 light carriers, 2 seaplane carriers, 11 battleships, 12 heavy cruisers, and a host of lesser vessels. The American carrier force (J) and cruiser-destroyer task force (K), the only United States groups in the area, could muster in major vessels only 3 large carriers and 7 heavy cruisers. In view of this disparity in strength, the American victory at Midway, as described in the text, was truly remarkable.

Enterprise and *Hornet* air groups had difficulty in locating the enemy, and *Hornet* dive bombers missed the Japanese ships altogether. The remainder of the early launching reached the enemy at about the same time as the *Yorktown* planes.

While the Japanese had no radar, from the number of planes reported Nagumo knew that more than one enemy carrier was present. The United States torpedo planes struck first, but they were slaughtered by enemy fighters without any of their torpedoes hitting; only 6 of the 41 torpedo planes returned to their carriers. Their martyrdom was not in vain, for the Japanese fighters could not again gain altitude, and the carrier lookouts barely had time to scream "Helldivers" before the bombers struck and roared away. Between 10:20 and 10:25 A.M., three bombs hit *Akagi*, one exploding on the hangar deck; four hit *Kaga*, two on the hangar deck; and three hit *Soryu*, one on the hangar deck. Gasoline caught fire, bombs and torpedoes exploded, and within 20 minutes these carriers were burning wrecks. All were gone by the next morning. The rest was anticlimax. Dive bombers from the *Hiryu* hit the *Yorktown* at 12:20 P.M., and two torpedoes struck her at 2:30 P.M. She was abandoned soon thereafter. The *Hiryu* herself was eliminated at 5 P.M. by dive bombers from the *Enterprise*.

Yamamoto was still confident because he believed that the disabled American carrier was the only one present. He recalled the Aleutian carriers, and at 7:15 P.M. ordered his surface force to move in for the kill. Two hours later, Nagumo enlightened him, and at 2:55 A.M. on June 5 he reluctantly ordered a general retreat. Shortly thereafter, the heavy cruisers *Mogami* and *Mikuma* collided while avoiding a United States submarine. Seriously damaged, they both fell behind. On the night of June 4, Spruance headed eastward to avoid enemy surface contact, and the next day his planes did not sight the enemy. On June 6, carrier planes finished off the *Mikuma*, but the battered *Mogami* returned safely to Truk in the Carolines. The last casualty was the abandoned *Yorktown*, still afloat with a destroyer alongside. Both ships were sunk by a Japanese submarine.

The question may be asked how a fleet of such size could be turned back by the meager force that the Americans were able to bring against it. The reason was the overconfidence of the Japanese. Too many objectives had been undertaken, and too many assumptions had been made in their own favor. The submarine line was established too late, and the morning search on June 4 was inadequate. On the United States side, there were superior intelligence and good luck as well as the dive bomber. This weapon, which the Americans had developed and the Japanese copied, settled the issue in five fateful minutes. Midway was a decisive battle, for the Japanese Navy never again gained the offensive.

Advance Through the Gilbert, Marshall, and Mariana Islands.—The task of halting and reversing the Japanese advance in the South Pacific and the need to build up United States forces caused a lull in operations in the Central Pacific for more than a year after Midway. The one exception was the recapture of Attu in the Aleutians. Since there were insufficient forces available to take the easterly and more strongly

held Kiska, it was bypassed for Attu, where the poorly prepared 7th Infantry Division was landed on May 11, 1943. This small island was secured in three weeks, but only after 11,000 men had been landed and the Japanese garrison wiped out. On August 15, a properly equipped and trained force of Americans and Canadians landed on Kiska, but they found that the Japanese had already evacuated the island.

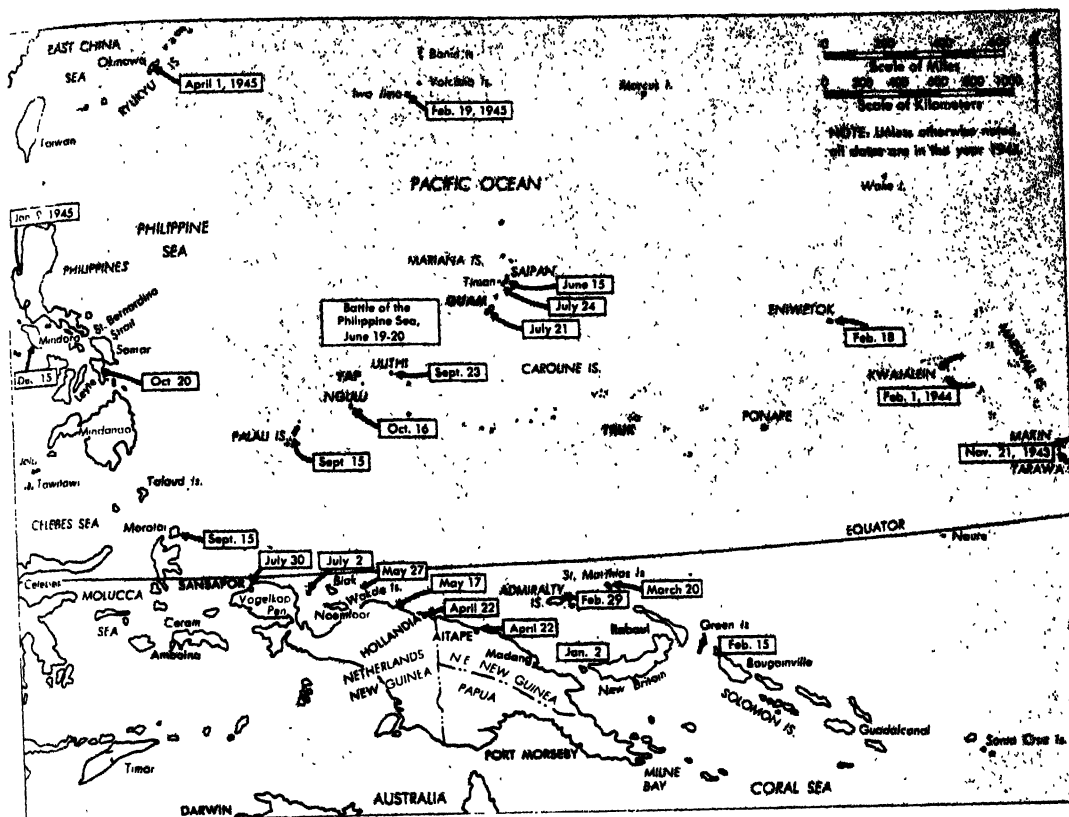

By the autumn of 1943 the Americans were ready to begin their strategic offensive. The geography of the Pacific offered them two directions of advance, both of which were adopted. One led along the north coast of New Guinea toward the Philippines; the other, directly across the Pacific from Hawaii. Both advances would bypass the Caroline Islands, believed to be strongly held by the Japanese. The Southwest Pacific campaign was to be conducted primarily by army forces, which would advance in shore-to-shore amphibious movements. The campaign in the Central Pacific would be primarily naval, supported by ground forces consisting mostly of Marines. It would require long overseas amphibious movements and heavy troop assaults on a few strongly held positions.

The major striking arm in the Central Pacific was a force of 16 heavy and light carriers with accompanying fast battleships, cruisers, and destroyers. Commanded by Rear Adm. (later Adm.) Marc A. Mitscher, it was named Task Force 58. Even this strong force, it was at first believed, would not be able to withstand attacks by land-based aircraft operating from the numerous Japanese-held islands in the Pacific. Early in each operation the carrier force would have to be relieved by its own land-based aircraft, and this would necessitate a step-by-step advance, first through the Gilbert Islands, then through the atolls of the Marshall Islands, and finally through the Marianas, which included captured Guam.

The Central Pacific campaign opened on November 21 with landings on Makin and Tarawa in the Gilbert Islands. At Tarawa the 2d Marine Division encountered the coral beaches and suicide resistance that would characterize Central Pacific assault operations. Casualties totaled 3,000, one third of them killed in three days of bitter fighting. This costly experience brought about improved amphibious techniques. It also revealed that the threat of enemy land-based aircraft was not as strong as had been supposed, and that naval forces could remain in the area of their objectives for extended periods without extreme risks.

Nimitz therefore decided to bypass the eastern Marshalls and seize Kwajalein. This was accomplished on Feb. 1-8, 1944, without committing the 10,000 troops of the reserve. These were used to take Eniwetok, the largest of the western Marshalls, but before this was attempted, the Japanese air bases in the Caroline and Marshall Islands were neutralized. Three carrier groups of Task Force 58 struck Truk in the Carolines on February 17-18, sinking 39 ships and putting 270 planes out of action. A strike against the Marianas on February 22 netted 150 more planes and valuable photoreconnaissance. Eniwetok, first scheduled for capture in May, was secured on February 18-23.

The assault on the Marianas was not scheduled to take place until June, and assault and

Map 46. ADVANCE ACROSS THE PACIFIC (Nov. 21, 1943–April 1, 1945). Initially, all American resources in the Pacific had to be employed to stop the Japanese advance in the Solomon Islands and eastern New Guinea. By late 1943 the tremendous production feats of United States industry provided sufficient resources for Adm. Chester W. Nimitz' Central Pacific forces to permit them to take the offensive against the Gilbert Islands. Thereafter, the forces of Nimitz and Gen. Douglas MacArthur converged in a two-pronged offensive across the Pacific, as shown. To avoid heavy losses of the kind suffered at Tarawa, such strongly fortified Japanese bases as Truk and Yap were bypassed and isolated.

amphibious forces returned to the Hawaiian Islands for training and staging. Task Force 58, however, with its afloat logistical support now in the anchorage at Majuro in the Marshalls, remained in the Western Pacific, supporting Gen. (later General of the Army) Douglas MacArthur's invasion of Hollandia, New Guinea, in April.

The Japanese mobile forces had not reacted to the Gilbert and Marshall advances. They withdrew first from Truk to the Palau group and then to Tawitawi in the Sulu Archipelago of the Philippines. The first Combined Fleet commander, Yamamoto, had been shot down on a flight to the Solomons a year before. His successor, cautious Adm. Mineichi Koga, was himself lost in an airplane accident in March 1944. The new fleet commander, Adm. Soemu Toyoda, took over with orders to seek action under favorable circumstances. Believing that the Americans were committed to the single line of advance through the Southwest Pacific, he stationed a surface force in the Moluccas and concentrated his land-based aircraft and submarines to cover it. He hoped to draw Task Force 58 into the area.

Instead the Central Pacific Fleet (now the Fifth Fleet) under Spruance struck the Marianas. Amphibious forces under Vice Adm. (later Adm.) Richmond K. Turner, numbering

555 ships, lifted 170,000 troops from the Hawaiian and Solomon Islands. The first landings were made at Saipan on June 15, 20,000 men being put ashore on that day. As at Tarawa, they met stiff resistance. Saipan was the strong link in the defense chain of the Japanese, and they were determined to hold it.

On learning of the Marianas attack, Toyoda ordered his surface and rebuilt carrier force to concentrate at sea east of the Philippines. United States submarines off Tawitawi and in the San Bernardino Strait reported this approach, and Mitscher wanted to advance with Task Force 58 to meet the Japanese and be within easy striking range at dawn of the day of contact. He knew that the enemy's striking range was 300 miles, whereas his own was only 200 miles because of the armor and self-sealing tanks in American aircraft. Spruance refused to permit Mitscher to adopt this course, since such an advance might uncover the ground and amphibious forces. The Japanese therefore had the offensive and attacked in four raids throughout daylight of June 19. To meet them, Mitscher put every available fighter in the air, and then launched his other planes to keep the carrier decks clear for rearming and refueling. With excellent fighter direction, the Japanese raids were met from 50 to 70 miles beyond the task force. There then took place what has

A battle-weary Marine quenches his thirst during the hard fighting for Saipan (June 15-July 9, 1944).

become known in the United States Navy as the "Marianas Turkey Shoot." Of the 326 Japanese planes attacking, 227 were lost, as compared with an American loss of 26. Only 3 United States ships suffered minor damage. In the midst of the Japanese flight operations, United States submarines hit 2 of their 3 largest carriers; both caught fire and sank that afternoon. The Japanese retreated, followed by Task Force 58, but contact was not made until 4 p.m. on June 20 at extreme range. Mitscher sent off one raid of 216 aircraft, which sank the carrier *Hiyo* and damaged 4 other ships. This ended the battle, and the Japanese carrier force was finished for the rest of the war.

On Saipan the 2d and 4th Marine divisions and the 27th Infantry Division, numbering 59,000 men, secured the island by July 9 after hard fighting in which they suffered 13,000 casualties, 3,000 of them killed. The Japanese defense force, which comprised 30,000 army and naval landing troops, was virtually wiped out. After heavy bombardment by army artillery and naval gunfire, nearby Tinian was taken easily between July 24 and August 1. The landings for the recapture of Guam, largest of the Marianas, had to be postponed on the approach of the Japanese Fleet, but were finally made by the 3d Marine and 77th Infantry divisions on July 21 after 11 days of intensive bombardment. The island was secured by August 10.

The seizure of the Marianas, which cracked the Japanese defense line, was the beginning of the end for Japan. The elimination of the Japanese carrier-based air strength uncovered the Philippines for MacArthur's forces, and the following November saw the first B-29 raids. A naval base was established on Guam, and Nimitz transferred his headquarters there. Spruance and his staff returned to Pearl Harbor to

plan future operations, while Adm. (later Admiral of the Fleet) William F. Halsey, former commander of the Third Fleet, which was to work with MacArthur in the invasion of the Philippines. The Japanese and most Americans believed that the Third Fleet was another naval force, but only the top commands had changed. The ships with their splendid engineering plants were the same.

Submarine Campaign.—A submarine's ability to submerge makes it a unique weapon in naval warfare. It employs stealth and therefore cannot easily be integrated into naval tactical formations. It must operate alone or with its own class, whether employed against combat ships or against merchant shipping. The Japanese used their submarines almost exclusively against combat ships but the United States submarine effort was directed primarily against merchant shipping and in effect constituted a blockade of Japan.

The United States submarines employed in World War II were mostly of the *Gato* class, the 1941 design displacing 1,525 tons on the surface, 311 feet long, with a surface speed of 20 knots and a cruising radius of 12,000 miles. They were armed with 24 torpedoes with six tubes forward and four aft and a 3-inch gun and four machine guns, and they had good radar, sonar, and optical equipment. Their complement was 8 officers and 80 men. Submarines of this class were excellent ships, but their primary weapons, torpedoes, were inferior to those of the Japanese, and many were found defective as a result of faulty peacetime testing procedures. The faulty torpedoes had been fitted with magnetic exploders that would not explode. It was eventually discovered that the torpedoes were running too far below their depth settings to activate magnetically, but when this was corrected the exploders began firing prematurely in latitudes near the equator. When the magnetic feature was deactivated, the mechanical exploders failed to work. Finally a resourceful commander conducted his own field test on a tanker that he had disabled off Truk. Of 15 torpedoes used, 9 failed to explode after careful checking and under ideal firing conditions. He saved his last torpedo to take back to Pearl Harbor for evidence. Exhaustive tests conducted there disclosed the defects and in September 1943, 21 months after the commencement of the Pacific war, the first fleet-type submarine went to sea with torpedoes in which her crew had confidence.

Following the Pearl Harbor attack, the chief of naval operations issued orders for unrestricted submarine warfare. This was a change in American traditions and doctrine, which had required submarines to be used in accordance with international law and primarily against combat ships. Whatever the reasons for the change, it was a militarily sound decision, for Japan's vital arteries were her sea lines of communications from her resources areas.

At the outbreak of hostilities, 28 submarines were attached to the Asiatic Fleet. These accomplished little against the Japanese initial advance into Southeast Asia, but in 1942 submarines based on Australia and at Pearl Harbor began their relentless campaign against the Japanese supply lines. At the beginning of the war, Japan had 6,100,000 tons of shipping, and she acquired an additional 800,000 tons by captures. The total was constantly reduced, slowly until

December 1943 and then sharply, until by 1945 it had been cut to 1,800,000 tons. Most of the ships that remained were in the Sea of Japan, which was still closed by mines to United States submarines. The attrition of Japanese shipping caused shortages in raw materials, slowing industrial production. Shortages in aviation gasoline curtailed pilot training, and a major portion of the fleet had to be based in Southeast Asia, near the oilfields but at a distance from repair and training facilities. (United States submarines had sunk 110 tankers.)

Japanese antisubmarine methods were inept. Merchant ships sailed singly until 1942, and convoys remained small throughout the war. United States submarine attack groups, called wolf packs, seldom had to exceed 4 ships. Commanders adopted hazardous tactics, attempting difficult shots and often operating on the surface at night in order to make use of high speed for continuing attacks. At first the submarines had little success against combat ships. During the first two years they sank only 1 heavy cruiser, 1 light cruiser, 6 destroyers, and 3 submarines. The heavy cruiser *Kako*, returning from victory at Savo Island in 1942, was sunk by the lowly S-44, a World War I type using old-style torpedoes with simple contact exploders. In the advance across the Pacific, Spruance skillfully employed submarines by placing them in narrow waters through which the enemy would have to pass. He left the actual direction of their operations to Vice Adm. Charles A. Lockwood, commander of submarines in the Pacific, the man who had solved the problem of the faulty torpedoes. Submarines now began to obtain good shots and transmit accurate information on enemy movements. The submarine contribution to success in the battles of the Philippine Sea and Leyte Gulf in 1944 was large. In November of that year, United States submarines sank the battleship *Kongo* north of the Philippines and the giant carrier *Shinano* in the Inland Sea, the latter only 10 days after she had been commissioned.

Submarines also performed lifeguard service, recovering 504 aviators downed in carrier strikes or B-29 operations. Among other special missions were mining, reconnaissance, and contact with coast watchers, guerrillas, and other isolated groups. A total of 52 United States submarines were lost during the war. Despite poor Japanese antisubmarine methods, more were sunk by escorts than by patrols, mines, aircraft, and other means; 3 were sunk by their own countrymen.

Throughout the war the Japanese used their submarines poorly. A single exception occurred in 1942 in the early Solomons campaign, when they sank the carrier *Wasp* and 4 other ships and damaged a battleship and another carrier. For some reason they limited their submarine operations primarily to combat ships, never learning, or refusing, to use them against the long and vulnerable United States supply lines. Attempts to integrate submarines into the Pearl Harbor and Midway operations proved fruitless, and in the late days of the war, when submarines might have defended the homeland, they had to be used to feed or evacuate garrisons isolated by the United States leapfrog strategy. The Japanese Army built submarines of their own for this purpose. Improved United States antisubmarine methods, the product of experience in the tough battle of the Atlantic, caused heavy Japanese submarine losses late in the war. Of 27 sub-

marines sent out during the Marianas campaign, 17 were sunk. In May 1944, the destroyer escort *England* accounted for 7 in 10 days.

In numbers, Japanese submarines about equaled those of the United States, and their torpedoes were far superior. Sound gear was poor, they had no radar, and the morale of their crews did not match that in United States submarines. Nevertheless, they could have constituted a dangerous threat to United States victory if Japanese naval leaders had not been blind to the realities of modern war.

Iwo Jima and Okinawa.—Like the Japanese in April 1942, the Americans in the Pacific in October 1944 were confounded by their successes. The question was not what to do next but how to do it. In the opinion of the AAF, bombing of the home islands would bring Japan to her knees, but the Army considered that an invasion would be necessary. The Navy's main job was virtually completed. Command of the sea had been won, and sea lines of communication to the Western Pacific were secure. The submarine blockade would continue, but other naval forces would be used to support ground and air operations.

After the Marianas campaign, Spruance had recommended Okinawa as the next step. He was overruled, since MacArthur wanted to return to the Philippines and Adm. (later Admiral of the Fleet) Ernest J. King, chief of naval operations, advocated the invasion of Taiwan (Formosa). The Army, however, claimed that the latter would require 9 divisions more than would be available in the Pacific before the fall of Germany. A plan proposed by Nimitz was finally accepted: the occupation of Luzon, supported by Central Pacific forces, to be followed by the occupation of Okinawa as a base for operations against Japan. MacArthur's forces were at first scheduled to support the Okinawa campaign, but they were subsequently diverted to mopping-up operations in the southern Philippines and Borneo.

The need for the capture of Iwo Jima in the Volcano Islands between the Marianas and Japan soon became apparent. The early operations of the B-29's had been disappointing. The round trip of 2,700 miles required 16 hours; without fighter protection, bombing had to be carried out at 28,000 feet; and disabled planes with their crews were often lost on the long return flight. The only suitable island in the Volcano group was Iwo Jima. D-days were set for Luzon, Jan. 9, 1945; Iwo Jima, February 19; and Okinawa, April 1.

After losing the Marianas, the Japanese planned a new defense line that included Iwo Jima, Okinawa, Taiwan, Shanghai, and southern Korea. Ground forces in these areas were to hold out to the end without reinforcements. Suicide aircraft, named Kamikaze (q.v.) for the "divine wind" that had thwarted the last attempted invasion of Japan in the 13th century, would be used against the advancing enemy. The final battle would be fought in Japan itself. Bloody attrition was expected to bring the Americans to terms.

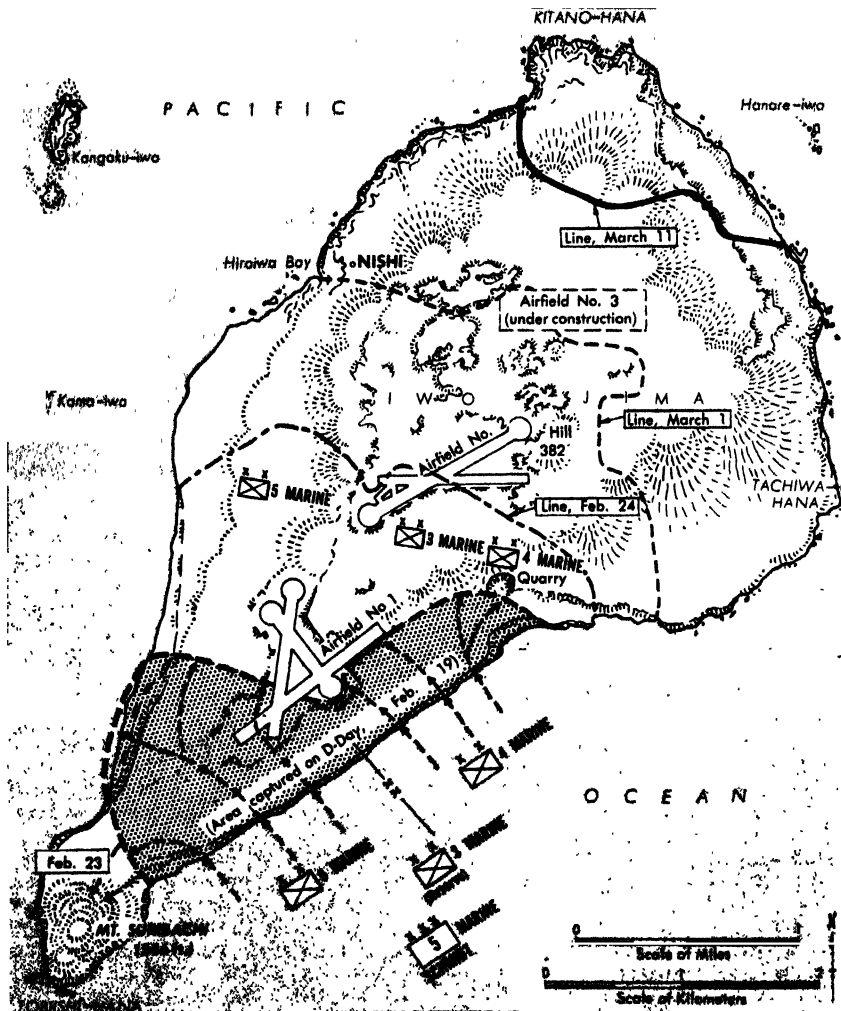

The Japanese knew that their enemy would eventually come to Iwo, and 21,000 troops were assigned to its defense. In October 1944, their commander, Gen. Tadamichi Kuribayashi, began to honeycomb the island with interconnected underground defensive positions 35 feet deep for protection against bombing and gunfire. Iwo,

shaped like a pork chop, is dominated by the 546-foot Mount Suribachi on its southwest point, while the northeastern section is a broad plateau. The airfield that the Americans wanted was in the center of the island, and the only suitable landing beaches were in the south near Suribachi. Kuribayashi therefore built his defenses on this mountain and in the north, although the entire island could be covered by artillery and mortar fire.

Operations commenced on Feb. 16, 1945, with preliminary bombardments. At 9 A.M. on February 19, assault troops of the 4th and 5th Marine divisions landed without much opposition and moved 300 yards inland. Then the guns on Mount Suribachi opened up, and the Marines suffered heavily. Nevertheless, they succeeded in crossing the southern end of the island by 6 P.M., and sufficient supplies were landed to ensure that the beachhead would be held. As enemy positions were disclosed, call-fires from the fleet were employed, and on February 24 the 3d Marine Division was landed. Mount Suribachi itself was taken on February 23, and the photograph of the raising of the American flag there became one of the best-known pictures of the war. The 3 divisions swung to the north, and the bloody work of destroying the Japanese defenders continued.

American casualties totaled almost 25,000, including 6,800 killed. Only 216 Japanese surrendered. Organized resistance ended on March 16, but a stricken B-29 had made the first emergency landing March 4. To the Marines Iwo Jima meant ugly death; to the B-29 crews, a godsend.

Okinawa, the next island on the Central Pacific's schedule of captures, is located 350 miles southwest of Kyushu, the southern main island of Japan. About 60 miles long and from 2 to 18 miles wide, it has two harbors and much flat terrain suitable for airfields. It was to be the base for the army ground and air forces that would be available, following the surrender of Germany, for the assault on Japan. Planning for Okinawa began with a study by Nimitz' staff, headed by his planner, Rear Adm. (later Vice Adm.) Forrest P. Sherman. Spruance was again to have over-all command. The ground force would be the Tenth Army under Lt. Gen. Simon B. Buckner, Jr., composed of the Army's 24th Corps of 4 divisions and the Marine 3d Amphibious Corps of 3 divisions with a division in reserve. The combat troops to be landed numbered 172,000; service troops, 115,000. Landings were to be made on the southwest coast near the airfield, which was to be seized quickly and put into operation for the land-based aircraft that would

Map 47. CAPTURE OF IWO JIMA (Feb. 19-March 16, 1945). Iwo Jima was a natural objective for the Americans. Within fighter and medium bomber range of Tokyo, it allowed fighter planes to escort and protect the B-29 bombers. It also provided a haven for B-29's in emergencies. The capture of Iwo, perhaps the most heavily fortified island attacked during the war, testified to the spirit and courage of the United States Marines. Though 6,800 Marines died on Iwo, by the end of the war emergency landings had been made on the island by 2,251 B-29's, carrying 24,761 crewmen, who otherwise might have found watery graves in the vast Pacific.

relieve the carrier forces. The Kerama-retto, a group of islands west of Okinawa, would be taken to provide anchorages for the auxiliaries servicing the naval combat forces. A British carrier task group would participate in the operation, covering the southern approaches to Okinawa.

Japanese forces on the island consisted of 77,000 well-trained army troops and 20,000 Okinawan militia and labor troops, all commanded by Lt. Gen. Mitsuru Ushijima. In accordance with the new Japanese policy, the invading force would not be resisted on the beaches but at strong positions inland, in this case in the southern part of the island. The army was to hold fast until air and naval forces, primarily suicide types, had forced the Fifth Fleet to withdraw, leaving the United States ground force unsupported. Between 2,000 and 3,000 Japanese planes would be available from 65 airfields in Taiwan and 55 airfields in Kyushu. The closest Japanese airfield was only 150 miles away.

Operations began on March 18-19 with strikes by Task Force 58 against Kyushu airfields and shipping in the Inland Sea. The results were disappointing, and 116 planes were lost and 3 carriers damaged, the *Franklin* seriously. The fight of the *Franklin's* crew to save their vessel was one of the epics of the war. More productive were the B-29 operations, striking Kyushu airfields and mining Shimoneseki Strait between the Inland Sea and the Sea of Japan. During the last days of March, 1,300 ships converged on Okinawa. Task Force 58 began preassault strikes on March 23, and the next day old battleships moved in to commence the naval bombardment. On March 26-28, the Kerama-retto were occupied without resistance, and a nest of 350 suicide boats was discovered. Service ships and patrol planes moved in, and from March 28 to April 8 tankers fueled an average of 23 ships a day.

On April 1, 4 divisions landed on Okinawa. They encountered no opposition, and by 6 P.M. about 50,000 troops were ashore in a beachhead 8 miles long and 3 miles deep. The 6th Marine Division turned to the north, and by April 27 had secured that weakly held portion of Okinawa as well as Ie-jima, where an airstrip was made operational early in May. The 24th Corps, which had turned to the south, was stopped when it reached the first Japanese defense line on April 6. This line was not broken until April 24, and the advance bogged down again four days later. A Japanese counterattack on May 4-5 was repulsed, and Buckner then launched his principal attacks on both flanks. The Japanese line was finally broken on May 31, but organized resistance did not cease until June 21. Buckner was killed in action three days earlier.

During this long period the naval forces had to remain in the area, supporting the land operations with air strikes and gunfire and covering the reinforcing amphibious echelons. They were unable to use their great asset, mobility, and were forced to stay and absorb 1,465 aircraft attacks, most of them Kamikaze suicide raids. On April 6-7, the fleet was raided by 350 aircraft, which sank or damaged 30 ships. Similar raids continued for two and one-half months but gradually decreased in intensity, the last one of 45 planes taking place on June 22. By then, 15 naval vessels had been sunk, none larger than a destroyer, and 200 damaged.

On April 7, the Japanese Navy had its *Götterdämmerung*. The giant *Yamato*, flagship

Wide World

of Yamamoto at Midway, plus a cruiser and 8 destroyers with the last 2,500 tons of oil available left the Inland Sea for a suicide attack on the naval forces off Okinawa. Two United States submarines reported this force on the evening of April 6, and it was located again at 8 A.M. the next day and kept under surveillance. Beginning at noon, carrier plane attacks sank the *Yamato*, the cruiser, and 4 of the destroyers. American losses were 10 planes and 12 men. By June 10, decreased Japanese resistance ashore and the buildup of land-based air strength permitted the release of Task Force 58, which had been at sea for three months. The strain on the high command of the Fifth Fleet had become almost unendurable, and toward the end of May, Nimitz took the unprecedented step of relieving Spruance, Mitscher, and Turner by their opposite numbers of the Third Fleet before the end of the campaign.

Bombing of Japan.—No final plans for the defeat of Japan had been accepted by the United States Joint Chiefs of Staff (JCS) by early 1944, but it was expected that the air offensive against that country, like that against Germany, would be made in conjunction with other operations. The AAF, however, believed that in the B-29 they had a weapon capable of removing Japan from the war by mass bombing alone. This aircraft, with a range of 1,600 miles, had only been developed in 1939, but with shortcuts in testing and procurement it was coming off the production lines in such quantities as to be ready for combat early in 1944. High AAF officers were naturally anxious to get it into active operations as soon as possible.

It was anticipated that the Marianas, lying 1,350 miles south of Honshu, would provide ideal bases for B-29 operations, but these islands were not scheduled for capture until June, and several more months would be needed to construct airfields. China was the only area then in Allied

Map 48. SEIZURE OF OKINAWA (April 1-June 21, 1945). The seizure of Okinawa was essential to eliminate Japanese bases in the Ryukyu Islands and to provide air bases for support of American operations against Japan proper. As at Iwo Jima and Tarawa, it was necessary to reduce methodically the strong Japanese defenses at the cost of heavy casualties. It took from April 6 to April 24 for the Tenth Army to break the Machinato Line, and from April 28 to May 31 to pierce the Shuri Line.

hands from which attacks could be made on the main islands of Japan with the B-29. The planes would have to be based in India, and gasoline and bombs ferried into China by air for staging from fields there. Despite such logistic drawbacks, it was decided to proceed with this plan.

The long-range B-29 presented a command problem. The AAF was always reluctant to place strategic bombers outside of its own chain of command, fearing that the effects of concentration in mass bombing would be lost if used to support other types of operations. It also considered that the range of the B-29 transcended theater boundaries. Command difficulties were already evident in the China-Burma-India theater, and similar trouble might develop in the Pacific as the two advances in that area converged on Japan. AAF historians credit Admiral King with proposing the command arrangement that was finally approved. The Twentieth Air Force, the B-29 over-all command, would remain directly under JCS with the AAF member, Gen. (later General of the Air Force) Henry H. Arnold, acting as its executive agent. Theater commanders were authorized to use B-29's in their areas in the event of a strategic emergency, and they could request assistance by them at other times.

The China B-29 operation began in June 1944 with a single wing assigned to the 20th Bomber Command. The logistic burden proved immense, and little was achieved in proportion to the effort expended. Combat aircraft were forced to transport most of their own gasoline and bombs for staging; sorties averaged only two monthly, and no more than 800 tons of bombs were dropped on Japan, although some damage was done to steel plants in Manchuria. The effort was abandoned in March 1945.

Following the capture of the Marianas, a gigantic B-29 base program was initiated. Credit for the speed with which it progressed is due Lt. Gen. Millard F. Harmon, commander of the AAF in the Pacific, who had to compete for priorities in a Navy theater. Naval construction battalions and Army aviation engineer battalions built three airfields on Guam, two on Tinian, and one on Saipan. The general depot was on Guam. The 21st Bomber Command in the Marianas was placed under the command of Brig. Gen. Hayward S. Hansell, Jr. Its first wing arrived in October 1944. The initial mass attack of 111 aircraft was made on Japan on November 24. Only 88 aircraft reached the bombing point, and these dropped their bombs at a high altitude through bad weather. The results in subsequent

raids continued to be disappointing, with high operational losses, especially on the long over-water return flight. In January 1945, Hansell, who continued to maintain his faith in high-level precision bombing, was relieved by Maj. Gen. (later Gen.) Curtis E. LeMay, an experimenter and a driving executive.

The capture of Iwo Jima eased the B-29 problem. Accompanying fighters and air-sea rescue units could be based on the island, and emergency landings could be made halfway home. Approximately 2,400 such landings were made in the subsequent months of the war. The number of men saved could not be determined, but the AAF accepted King's estimate that it exceeded the number lost (8,800) in the capture of the island.

Incendiary bombing had proved effective in Germany and many AAF officers believed that it would be even more effective against Japanese cities, where wood construction predominated and housing areas surrounded industrial plants. LeMay, who had already made the decision to bomb at low altitudes, now decided to undertake

a major fire effort. The first night incendiary raid against Tokyo on March 9 burned out 15.8 square miles of the city, killed 83,000 persons, and injured 40,000. Within the next 10 days four of Japan's other large cities received similar treatment. These raids finally brought home to the people of Japan what the war really meant.

During March and April, B-29's supported the Okinawa operation by raids on Kyushu and by aerial mining of Shimonoseki Strait. This last operation, made at the request of the Navy, which had no planes suitable for the work, proved so successful that it was extended to ports on the Inland Sea and virtually ended traffic in that important body of water. By the end of July, B-29 aircraft were raiding in numbers of over 500. A total of 64 cities had been bombed, while losses in aircraft dropped to a negligible figure. Attacks became so bold that leaflets were dropped warning cities of their impending doom. LeMay kept driving his men at an exhausting pace, hoping to force a surrender before the invasion.

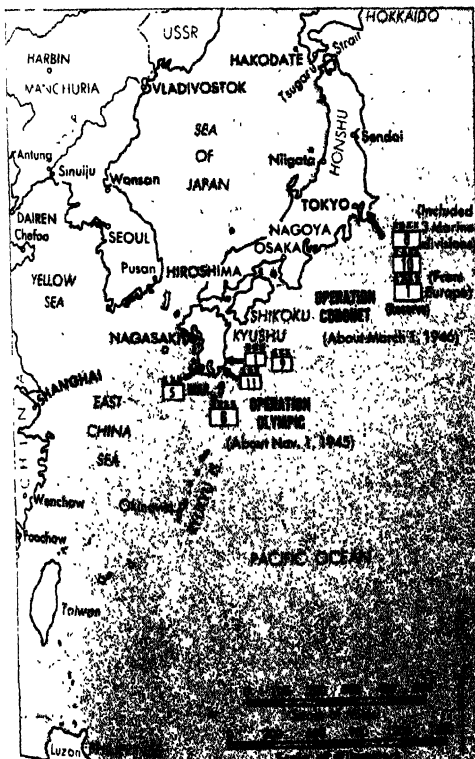

Atomic Bombing and Surrender.—Meanwhile, preparations were being made for the invasion of the Japanese home islands, with landings scheduled for Kyushu in November 1945. This assault, code named Olympic, was to be made with Army and Marine units then in the Pacific. Landings on Honshu, code named Coronet, were to be made in March 1946 aided by forces deployed from Europe.

By this time a search for peace was under way in Japan. Interrogations made after the war indicated that many Japanese leaders and intellectuals were convinced after the fall of Saipan that their country could not win, and the B-29 bombings stimulated efforts to bring about a surrender. In July 1944, the militaristic cabinet of Premier Hideki Tojo fell. Its successor, committed to continue the war, also fell after Okinawa was invaded. The new cabinet was directed by Emperor Hirohito to seek appropriate means to end hostilities even on terms unfavorable to Japan. Army members of this cabinet, however, were still reluctant, since the Americans had not as yet met the full force of the Japanese Army and 8,000 aircraft had been hoarded to repel the invasion effort.

The Soviet Union ominously announced to Japan in April 1944 that the neutrality pact between the two countries would not be renewed. Peace overtures were made through the USSR, but the Russians stalled. At the Potsdam Conference (July 17–Aug. 2, 1945), Joseph Stalin did not mention these overtures to President Harry S. Truman, who already knew of them through intelligence sources. In the Potsdam Declaration of July 26, the Allied leaders did announce that for Japan "unconditional surrender" would apply to the armed forces alone. This condition for negotiations was not acceptable to the Japanese cabinet, because it made no mention of the future status of the emperor. Such was the situation on August 6, when an atomic bomb was dropped over Hiroshima.

Six years before, President Franklin D. Roosevelt had received a letter from Dr. Albert Einstein, in which the eminent scientist referred to the possibility of a uranium bomb of tremendous power. This initiated a large but secret project known as the Manhattan Engineer District, under Maj. Gen. (later Lt. Gen.) Leslie R. Groves, for the development and construction of such

Map 49. PLAN FOR THE INVASION OF JAPAN PROPER (November 1945–April 1946). Even as the United States Tenth Army assaulted Okinawa, the Sixth and Eighth armies in the Philippines prepared for the invasion of Japan proper. Operation Olympic, the capture of Kyushu to provide air bases to support the assault on Honshu, was to be undertaken by the Sixth Army about Nov. 1, 1945. Operation Coronet, the final attack on Japan, was to be a massive affair involving the Eighth Army from the Philippines, the Tenth Army from Okinawa, and the First Army, deployed after the collapse of Germany to initial bases in the Philippines. Supporting echelons were to be moved from all major bases in the Pacific and from as far east as the west coast of the United States. Fortunately for both sides, the surrender of Japan on Aug. 14, 1945, made these operations unnecessary.

bombs. The first was exploded successfully at Alamogordo, N.Mex., on July 16, 1945. This information was sent to President Truman, who gave the authority to drop an atomic bomb on Japan after August 3. The fissionable material available was shipped to Saipan aboard the cruiser *Indianapolis* and by air. A squadron of B-29's organized for the purpose was already on the island, and one of its planes, piloted by Col. Paul W. Tibbets, Jr., was assigned to make the first drop. Capt. (later Rear Adm.) William S. Parsons, the weapon commander, made the final adjustments in flight. The bomb was dropped over Hiroshima at 8:15 A.M. on August 6, and exploded at about 2,000 feet, destroying 4.7 square miles of the city. More than 71,000 persons were dead or missing.

The Russians declared war on Japan on August 8 (effective August 9) and were soon invading Manchuria, Korea, and southern Sakhalin. On August 9, the second bomb was dropped on Nagasaki. The emperor then advised acceptance of the Potsdam terms, to which the cabinet agreed provided the imperial system be retained. United States Secretary of State James F. Byrnes drafted a reply to the effect that the emperor must be subordinate to the supreme commander for the Allied powers (SCAP), his final status to be determined by free elections of the Japanese people. On August 14, on the emperor's advice, these terms were accepted, and hostilities ceased.

The surrender took people in the Pacific generally by surprise. Moreover, after the stubborn character of Japanese resistance experienced during the war and the nature of the Japanese government, it could hardly be assumed that the military would quietly acquiesce to a surrender decision made by political leaders. Occupation forces therefore had to be ready to meet resistance. General MacArthur was made supreme commander for the Allied powers on August 14,

and plans were immediately shifted from Olympic to the occupation of the Japanese home islands by the Sixth Army from the Southwest Pacific and of Korea below the 38th parallel by the 24th Corps from the Central Pacific. The Russians were to occupy Korea above that line. The landing date had to be postponed from August 28 to August 30 because of a typhoon. The first landings were made simultaneously by the 11th Airborne Division at Atsugi Airfield near Tokyo and by the 4th Regiment of the 6th Marine Division at Yokosuka Naval Base. Formal surrender took place on September 2 aboard the battleship *Missouri* in Tokyo Bay. The surrender was followed by Operation Magic Carpet, a rapid return of military personnel to the United States for demobilization. The greatest military machine that the world had known was allowed to pass out of existence before the fruits of victory had been secured.

Meanwhile, 2 Marine divisions were sent into Japanese-held northern China until the Nationalist forces of Generalissimo Chiang Kai-shek could occupy that area. A major error, as it later proved, was made in returning to Japan the disarmed Kwantung Army and the Japanese civil administrators. This and too early withdrawal of American forces helped to create a vacuum that the Chinese Communists were to fill.

Victory in the Pacific was not just the result of interservice cooperation; it was the summation of three arms and three strategic doctrines employed to their highest capabilities. Without the seizure of bases by ground forces, there would have been no command of the sea. And without command of the sea, the B-29's would not have had the opportunity to bring Japan to her knees before the invasion of her soil. The realization of these three military capabilities was made possible by the rich resources and intelligent labor force that gave the United States an almost un-

limited economic potential for war. A heartland facing on two oceans, the American nation could with one hand fight a continental war in Europe and with the other a maritime war in the Pacific. In the latter its industrial power permitted two advances through areas in which the strategies of its land and sea forces could best be exploited. These advances supported each other and kept the enemy off balance. The Americans were able to profit by their mistakes, exploit opportunities, and, when necessary, see the big picture. The Japanese could not, and therein lay the margin of victory.

JOHN D. HAYES,

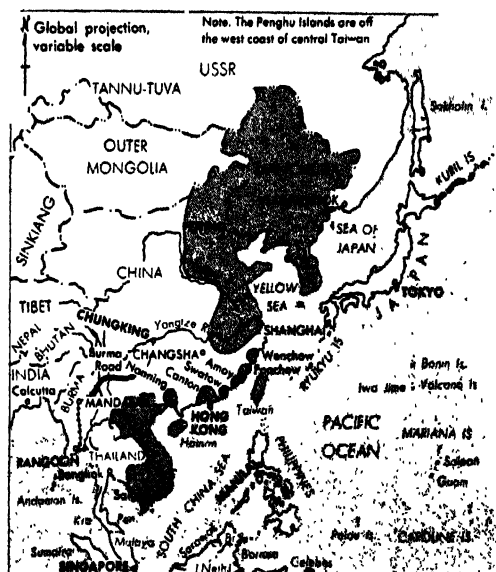

Rear Admiral, United States Navy (Retired).

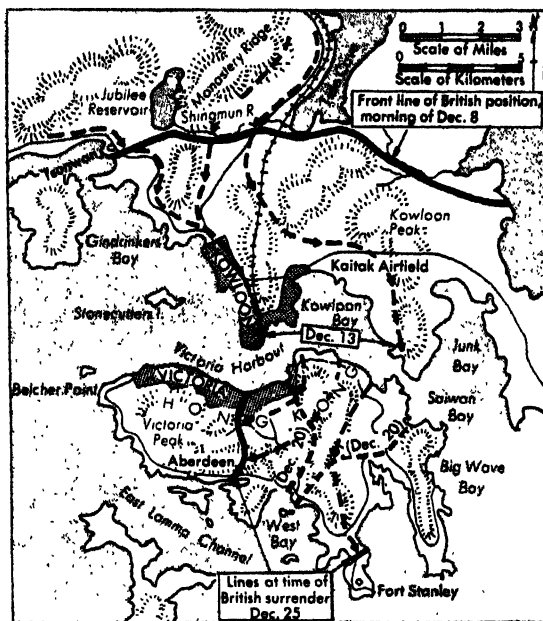

11. War in Eastern Asia

When Japan went to war with the United States, Great Britain, and the Netherlands in December 1941, she was already well established on the Asian mainland from Manchuria in the north to Indochina in the south. Since she possessed sovereignty over Taiwan (Formosa) and the Penghu Islands (Pescadores), she was poised to strike quickly toward the so-called Southern Regions, which included the Philippines, Borneo, Celebes, Java, Sumatra, Malaya, Thailand (Siam), and Burma, an area rich in such raw materials as oil, rubber, tin, and many other products of which she was desperately short. Of the 51 infantry divisions which composed the Japanese Army in 1941, 43 were committed to the Asian mainland: 13 to Manchuria, 2 to Korea, 25 to China, 2 to Indochina, and 1 to the island of Hainan. In addition, 2 of her 5 air divisions were also committed to Asia. She had therefore only a comparatively small force available to undertake the capture of the Southern Regions. The attacks on the Philippines and the

Netherlands East Indies are discussed in section 9. *War in the Southern and Southwestern Pacific*, and this section therefore deals only with operations on the Asian mainland: Thailand, Malaya, Burma, China proper, and Manchuria. A division from China was given the task of seizing Hong Kong; the Twenty-fifth Army, consisting of 4 divisions (of which only 3 were used) and an air division, was allotted to neutralize Thailand,

Map 50. JAPANESE PREWAR CONQUESTS IN ASIA. Japan's drive for empire began many years before World War II. She seized Taiwan from China in 1895 and annexed Korea in 1910. In 1931, on a minor pretext, the Japanese overran Manchuria. Ever-increasing demands on China brought on the Sino-Japanese War in 1937. The Japanese made substantial incursions into China proper and took control of the major Chinese ports. After the fall of France in 1940, the Vichy government was coerced into granting rights of transit in Indochina to Japanese troops, which eventually led to the occupation of all of Indochina. On Dec. 8, 1941, the Japanese controlled the areas shown.

Map 51. CAPTURE OF HONG KONG (Dec. 8-25, 1941). The first target of the Japanese was the British crown colony of Hong Kong. The British defense line, held by a few battalions, was quickly breached, and by December 13 the defenders had been driven from the mainland onto the island of Hong Kong. The Japanese crossed to the island in great strength and attacked persistently. Isolated and short of supplies and food, the British garrison surrendered on Christmas Day.

invade Malaya, and capture the British naval base at Singapore; and the Fifteenth Army, consisting of 2 divisions and an air division, was assigned the job of occupying southern Burma.

Japanese Advance in Southeast Asia: 1941-1942.—The invasion of Hong Kong began early on Dec. 8, 1941 (local time). The small garrison of this isolated outpost, consisting of two British, two Canadian, and two Indian battalions, attempted to defend the New (Leased) Territories on the mainland, but by December 13 had to withdraw to Hong Kong Island. The Japanese landed on its northern shores on the night of December 18-19 and gradually forced the garrison into the western part of the highly populated island. With no hope of reinforcement or relief and having suffered severe losses, the garrison surrendered on December 25. This freed the Japanese division to join the Sixteenth Army for the invasion of the Dutch territories farther south.

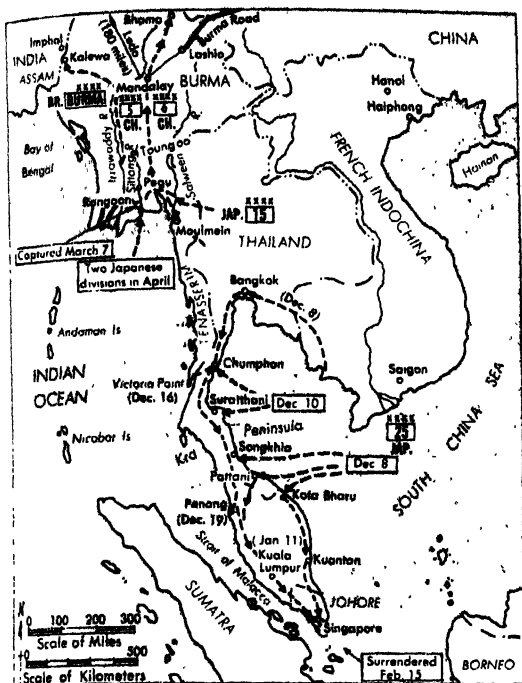

In the early hours of December 8 (local time), the Twenty-Fifth Army occupied Bangkok, thereby gaining control of Thailand, and landed a division at Songkhla (Singora) on the Kra Peninsula and part of another at Kota Bharu in northeastern Malaya. The Japanese quickly gained air supremacy, since their aircraft were far superior to and outnumbered the obsolescent Royal Air Force (RAF) planes. Two days later, Japanese torpedo bombers sank off the east coast of Malaya the *Repulse* and the *Prince of Wales*, the only two British capital ships in Eastern waters. This success ensured the Japanese complete control of the South China Sea. The British garrison of Malaya consisted of the Indian 3d Corps (two newly raised and semitrained divi-

sions), which held northern Malaya, and an understrength Australian division, which held northern Johore. Constantly outflanked by infiltration through jungle-covered country and by landings on the coast behind it, the 3d Corps proved to be no match for the highly trained and experienced Japanese divisions and was forced to withdraw southward. The Japanese occupied Penang on December 19, and Kuala Lumpur on Jan. 11, 1942. Despite a stand in northern Johore by the Australians, they had driven the mauled and dispirited defenders back into Singapore Island by January 31. Although the garrison had been reinforced by two hastily dispatched and almost untrained Indian brigades and, at the last moment, by a British division diverted while at sea on its way to Egypt, the defense of the island, by then isolated by sea and air, was a hopeless task. The Japanese landed three divisions on February 8-9, and by February 13 had forced the remnants of the garrison back into a tight perimeter ringed around Singapore itself. With the city and its large Chinese and Malayan population under heavy artillery fire, water supplies cut off, and the troops short of ammunition, the garrison surrendered on February 15. In conquering Malaya, the Japanese had gained an entrance into the Bay of Bengal and the use of the Singapore naval base.

The invasion of Burma began on Dec. 16, 1941, when a small Japanese detachment occupied unopposed Victoria Point at its southern extremity; in mid-January other detachments occupied points on the Tenasserim coast. The small Burma Army was reinforced during January with what India could spare, but when the main invasion began it consisted of only two ill-equipped divisions, composed of British, Indian and Burmese troops, supported by a very small air force, which included a squadron from Big Gen. (later Maj. Gen.) Claire L. Chennault's American Volunteer Group (Flying Tigers) in China. On January 20, two Japanese divisions crossed the Thai frontier east of Moulmein. Outflanking and outmaneuvering the Indian division facing them, they captured Moulmein on January 31, and by February 24 had forced the defenders back across the Sittang River.

In December 1941, Generalissimo Chiang Kai-shek, anxious lest the Burma Road, along which lend-lease supplies were reaching China from Rangoon, should be cut, had offered Chinese troops to assist in the defense of Burma. Their entry into Burma from the north in mid-February enabled the other division of the Burma Army (now reinforced by an armored brigade and other troops) to move south to help in the defense of Rangoon. The advance of the Japanese was, however, too rapid: they drove a wedge between the two divisions before a junction could be made, and on March 5 captured Pegu. Rangoon could no longer be held and, after some hesitation, was evacuated on March 7. Its garrison, escaping somewhat luckily from the encircling Japanese forces, withdrew up the Irrawaddy toward Prome.

The defense of central and northern Burma now rested on the Burma Army (two weak divisions) in the Irrawaddy Valley, and on the Chinese Fifth and Sixth armies (equivalent in strength to two American divisions) in the Sittang Valley on the direct railway from Rangoon to Mandalay. The Chinese were under the command of Lt. Gen. (later Gen.) Joseph W. Stil-

Map 52. FALL OF BURMA AND MALAYA (Dec. 8, 1941-May 20, 1942). The Japanese invaded Burma and Malaya in great strength, as shown. The limited British and Chinese forces available fought to stem the Japanese advances, but they were forced back by overwhelming power. On Feb 15, 1942, Singapore, bastion of British strength in the Far East, fell. By late May, the Allied forces had been driven from Burma into India and China.

well, who had also been appointed commanding general of the American China-Burma-India (CBI) theater in February 1942. The possession of Rangoon and the cessation of hostilities in Malaya enabled the Japanese to reinforce the Fifteenth Army in Burma with two fresh divisions, two tank regiments, considerable artillery, and a number of air regiments. They quickly advanced toward Mandalay in an attempt to destroy the defenders in the loop of the Irrawaddy River. Having captured Toungoo on March 30, they drove rapidly north, passing round the Chinese left flank, and by the end of April had cut the Burma Road at Lashio. The Burma Army had no alternative but to withdraw across the Irrawaddy. Burma could now no longer be held. The Burma Army and two Chinese divisions withdrew into Assam, the former by way of Kalewa to Imphal and the latter from Myitkyina to Ledo. The rest of the Chinese armies withdrew eastward across the Salween River into China. By the end of May 1942, the Japanese were in control of the whole of Burma and had occupied the Andaman and Nicobar Islands. They had thus attained in five months all their objectives and secured the western end of their long defensive perimeter around the Southern Regions.

With the control of the Strait of Malacca and the Bay of Bengal in their hands, the Japanese sent part of their naval forces, including aircraft carriers, into the Indian Ocean for a short time early in April to bomb Colombo and the naval base at Trincomalee in Ceylon and to raid the

shipping routes along the east coast of India. Neither the British nor the Japanese were seeking a fleet action but, before the enemy force withdrew to Singapore, its aircraft had sunk two British cruisers, a small aircraft carrier, two destroyers, and a corvette and had accounted for approximately 100,000 tons of merchant shipping.

The loss of Burma and of the command of the sea and air in the Bay of Bengal left India wide open to invasion by land or sea. Since the best Indian formations had been sent to Iraq and Egypt and the equivalent of three divisions had been lost in Malaya and Burma, there was little with which to undertake her defense until her many newly raised divisions were trained, equipped, and ready for battle. Strenuous efforts were therefore made to build up forces for her defense and that of Ceylon. Three British divisions were diverted from the Middle East theater, and an African division was sent from East Africa. A beginning was also made in the buildup of a large Allied strategic and tactical air force, including the United States Tenth Air Force, and the India-Burma Division of the United States Air Transport Command to ferry supplies from Assam across the "hump" to China, which was now cut off from all land access from the west. This entailed an enormous program of airfield construction in Bengal, Assam, and elsewhere in India, which stretched Indian engineering resources to their limit. Faced with the defense of her eastern frontier (an eventuality which had never been envisaged), India had also to reorientate her logistical organization and improve the very poor rail and river communications from Calcutta to eastern Bengal and Assam. In her efforts to do this she was hampered by having sent much of her river and coastal shipping and a large proportion of her meter-gauge railway locomotives and rolling stock to Iraq to help in its defense. The buildup therefore could only be accomplished over a longish period of time.

With the American naval victories of the Coral Sea in May and Midway in June 1942, the danger to India passed, and the main problem now facing the Allies was how to keep China in the war. To reach Kunming by road from Assam necessitated the reoccupation of northern and central Burma and the building of a road from Ledo through Myitkyina and Bhamo to join the original Burma Road. Since to accomplish this would take considerable time, it was decided to increase deliveries of supplies by the air ferry route to a tonnage sufficient to supply the needs of Chennault's Fourteenth Air Force and reequip approximately 30 Chinese divisions. The Chinese troops who had reached India in 1942, gradually reinforced by men flown from China, were reformed, equipped, and trained by Stilwell, who aimed at producing three elite Chinese divisions (each of 10,000 men) with tank and artillery support.

Operations in Burma: 1942-1943.—Gen. (later Field Marshal) Sir Archibald Wavell (later 1st Earl Wavell), the commander in chief in India, made every effort to take the offensive to recapture Burma as soon as practicable, but the means were not to hand until time allowed his land and air forces to be assembled and trained and his communications to the eastern frontier built up. Nevertheless, he launched an offensive in October 1942 by one division to

capture Akyab in coordination with an amphibious assault on the port. Maungdaw and Buthidaung were occupied on December 17, but the formation earmarked for the amphibious assault and its landing craft were delayed by extended operations to wrest Madagascar from the control of supporters of the Vichy French government. Wavell therefore decided to continue with the land advance and, when within striking distance of Akyab, to launch a short-range amphibious attack. The Japanese had meanwhile brought their forces in Arakan up to divisional strength, and early in March 1943 halted the land advance too far to the north of the port to make a short-range amphibious operation possible. They then launched a counteroffensive and by the break of the monsoon in May had recaptured Buthidaung and Maungdaw. Although Wavell's effort had failed, it brought to light defects in the organization and training of the rapidly expanding Indian Army. These were eliminated, and by the end of 1943 the British-Indian divisions had reached a pitch of training which made them equal to the Japanese.

In July 1942, Wavell formed a long-range penetration brigade (Chindits) under the command of Brig. (later Maj. Gen.) Orde C. Wingate. On Feb. 14, 1943, the Chindits, some 3,000 strong, crossed the Chindwin River and, supplied by air, penetrated deep into Burma without meeting much opposition and damaged the railway south of Indaw. Wingate then crossed the Irrawaddy into a somewhat waterless area, but its many roads and tracks enabled the Japanese to surround his force, which had to disperse and get back as best it could. By early June, only 2,200 men had got out of Burma to Assam or China. This incursion had little strategic value in itself, but it gave a considerable moral fillip to Britain and India and showed clearly that troops in jungle country could be supplied by air. Its greatest effect, however, was that it made the Japanese decide to improve their defensive positions in Burma by taking the offensive toward

Assam, a decision which was to prove fatal.

Campaigns in Burma and China: 1943-1944.—In November 1943, the Anglo-American South-east Asia Command (SEAC) was formed with Adm. Lord Louis Mountbatten (later 1st Earl Mountbatten of Burma) as supreme commander, and General Stilwell as his deputy, with the object of controlling all operations in Southeast Asia. In December, the United States Tenth Air Force and the RAF wings in India were combined into the Eastern Air Command under Maj. Gen. (later Lt. Gen.) George E. Stratemeyer. Meanwhile, plans were made to establish the 20th Bomber Command, equipped with long-range B-29 aircraft, at Chengtu in Szechwan Province, China, from where Manchuria and the Japanese mainland could be bombed.

The plans for the 1944 campaign prepared by the supreme commander included a combined thrust by Stilwell's Chinese forces from Leds toward Myitkyina, by British-Indian forces across the Chindwin toward Indaw, and by the Chinese Yunnan armies across the Salween with the object of reoccupying northern Burma and opening a land route to China. A subsidiary attack was to be made in Arakan to capture Akyab and if resources allowed, the Andaman Islands. Resources, however, did not permit an amphibious operation to be mounted in the Indian Ocean, and Chiang Kai-shek refused to commit his Yunnan armies across the Salween. The plans for 1944 had therefore to be reduced to a land advance toward Akyab, a drive down the Hukawng Valley toward Myitkyina, and an incursion by the Chindits (now enlarged to six brigades and known as Special Force) to the Indaw area to cut the enemy communications to the north and so assist Stilwell's thrust on Myitkyina. The Japanese, on the other hand, having decided to take the offensive, planned to advance in March 1944 across the Chindwin to capture the British base at Imphal, and to attack in Arakan in February to forestall the expected Allied advance in that area.

Map 53. OPERATIONS IN BURMA AND CHINA DURING 1944. It was not until the beginning of 1944 that the Allies could accumulate sufficient resources to launch a real offensive in Burma. Progress was slow against the Japanese resistance and counterattacks, but by the end of the year the area shown had been regained, and land communications had been reopened with China via the Leds Road (eastern portion of the Burma Road). Meanwhile, stung by B-29 air attacks from bases in southern China, the Japanese advanced as shown and captured the airfields. In 1944 also, they advanced their lines in the area of Chenghsien (now Chengchow).

At the end of the monsoon the Indian 15th Corps of the Fourteenth Army under the command of Lt. Gen. (later Field Marshal) Sir William Slim (later 1st Viscount Slim) was gradually approaching the strong defensive positions in Arakan covering Maungdaw and Buthidaung when, on February 4, the Japanese launched their offensive. They passed approximately 5,000 men behind the forward Indian divisions, thus cutting their communications. Supplied by air, these stood firm, and reserves brought forward threw back the Japanese with heavy loss. The British offensive was then resumed, and by the break of the monsoon in May the Japanese had been driven out of all their main defenses covering Akyab.

The Japanese offensive toward Imphal was launched by the Fifteenth Army in mid-March, but, on the assumption that Imphal would be captured in three weeks, inadequate logistical plans for its maintenance had been made, a mistake which was to prove disastrous. In accordance with the Fourteenth Army's prearranged plan, the Indian 4th Corps withdrew to prepared positions covering the Imphal plain as soon as the enemy crossed the Chindwin. The corps was isolated from India when the Imphal road was cut on March 29. Kohima was attacked on April 4 and surrounded by April 8. A division was flown into Imphal from Arakan, and the Indian 33d Corps was brought forward from India and concentrated at Dimapur. The Allies had by now gained air supremacy over Burma, and, supplied by an airlift, the 4th Corps was able to hold its position around Imphal and in May to begin a counteroffensive, while the 33d Corps, after relieving the Kohima garrison, took the offensive southward. By the end of June, the two corps had met, and the Imphal road was reopened. The defeated Japanese Fifteenth Army, short of food and ammunition, retreated to the Chindwin in considerable disorder.

Stilwell had begun his advance from Ledo toward Myitkyina in January. On orders from Chiang, the Chinese divisions did not press forward as fast as they might, but progress was made thanks to Merrill's Marauders (the 5307th Composite Unit led by Maj. Gen. Frank D. Merrill and the American counterpart of the Chindits), and by the end of March the Hukawng Valley had been cleared and entry into the Mogaung Valley secured. On April 28, the Marauders, reinforced by some Chinese regiments, began to move east across the mountains and then south to capture Myitkyina from the north by surprise. On May 17, this force occupied the Myitkyina airfield, but its exhaustion was such that, despite reinforcements brought in by air, it was unable to drive the Japanese from the town, and a four struggle began that lasted 11 weeks.

To assist Stilwell's advance, three brigades of Special Force were moved into Burma by air and by march route. By the end of March 1944, approximately 12,000 men, supplied entirely by air, were established around Indaw and had formed a block north of the town on the road and railway leading to Mogaung, thus effectively cutting the communications of the enemy forces facing Stilwell. The Japanese made repeated unsuccessful attempts to break the block, but it became evident early in April not only that the block might be overwhelmed by a newly arrived Japanese division, but that Special Force could not be maintained at Indaw during the monsoon.

Wide World

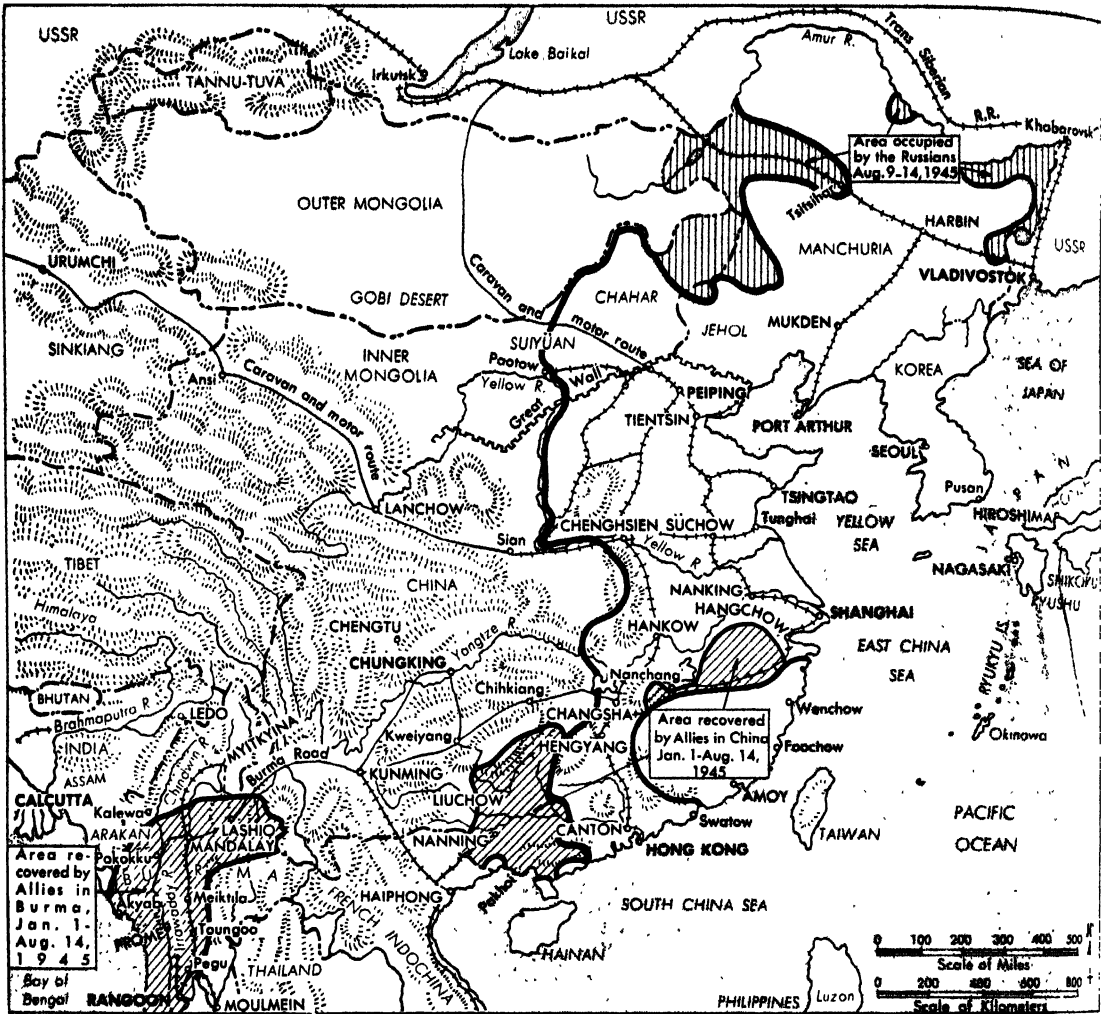

The special American unit known as Merrill's Marauders crosses a stream in northern Burma in pursuit of the retreating Japanese during the 1944 campaign.

It was therefore ordered to move north at the end of April, establish a new block nearer Mogaung, and come under Stilwell's command beginning on May 17.

By threatening to withdraw aid for the re-equipment of his armies, the Americans at last obtained Chiang's agreement to the Yunnan armies taking the offensive across the Salween on April 10. This offensive, however, failed to help Stilwell to capture Myitkyina, for an inferior Japanese force brought the Chinese to a halt by the end of June before a line of defended walled towns not more than 20 miles west of the Salween.

Special Force established its new block south of Mogaung on May 7 but was forced to abandon it with heavy loss on May 25. The Japanese were now free to reinforce Kamaing or Myitkyina but did not move quickly enough to do either. Stilwell occupied Kamaing on June 16, and a brigade of Special Force, with some assistance from a Chinese division, occupied Mogaung on June 26. Stilwell was now able to use the road to Myitkyina; his forces were reinforced and finally occupied the town on August 3. The capture of Myitkyina was of great value for, once airfields had been constructed and a pipeline built from Ledo to them, the air ferry could operate into China without flying across the "hump."

There was little more than sporadic fighting in China during 1942 and 1943. By the beginning of 1944, Chennault had established a base for the B-29's at Chengtu and a chain of airfields in eastern China astride the Hankow-Canton railway, from which the Fourteenth Air Force could support the Chinese armies. Since these latter airfields constituted a danger, the Japanese decided to eliminate them. In April and May, they cleared the Peiping (Peking)-Hankow railway, and at the end of May began to advance southward. Despite the support of the Fourteenth Air Force and at times of the B-29's, the Chinese armies were no match for the Japanese. By mid-December, assisted by an ad-

Map 54. OPERATIONS IN BURMA AND CHINA DURING 1945. The shaded areas in Burma and southern China indicate the territory recaptured from the Japanese by the Allies from Jan. 1, 1945, to the capitulation of Japan on Aug. 14, 1945. The shaded areas in Manchuria indicate the territory occupied there by the Russians from their entry into the war on August 9 to its end on August 14. The Russians also invaded northern Korea and occupied southern Sakhalin before V-J Day, and they continued on to occupy more of Manchuria and the Kuril Islands.

vance westward from Canton, the Japanese had occupied all but two of the American airfields in eastern China, had made contact with their garrison in Indochina, and had created a threat to both Kunming and Chungking. Meanwhile, in June, the B-29's from Chengtu had begun to bomb targets in Manchuria and western Japan.

Recovery of Burma and Final Operations Against Japan: 1944-1945.—In October 1944, Stilwell was recalled to Washington, and the CBI theater was divided. Maj. Gen. (later Lt. Gen.) Albert C. Wedemeyer replaced Stilwell as commanding general of the China theater and Lt. Gen. Daniel I. Sultan took command of the Burma-India theater, which remained part of SEAC. Soon after taking up his command, Wedemeyer, conscious of the threat to Chungking and Kunming, advised Chiang Kai-shek to concentrate a force of 30 Chinese divisions to meet it. To provide a trained nucleus for this force, he asked for the eventual return to China of all the Chinese divisions (by now numbering

5) operating in northern Burma; 2 were sent him in January 1945.

In Burma the Fourteenth Army relentlessly pursued the defeated Japanese throughout the monsoon. Despite appalling climatic conditions, which turned roads and tracks into quagmires, Kalewa was captured and bridgeheads were established across the Chindwin at many points by the first week in December 1944. Slim was now ready to advance into central Burma. He sent his 33d Corps in a wide sweep toward the Irrawaddy with Mandalay as its objective, and with great secrecy passed the 4th Corps southward from Kalewa to Pakokku, with Meiktila on the main enemy communications between Rangoon and Mandalay as its objective. By Feb. 1, 1945, supplied almost entirely by air, the Fourteenth Army had closed up to the Irrawaddy from a point 40 miles north of Mandalay, where it had seized bridgeheads across the river, to Pakokku 140 miles farther downstream. On the Arakan coast the 15th Corps began to advance as soon

as the monsoon abated and occupied Akyab, which had been abandoned by the Japanese two days earlier, on January 3. An amphibious attack was launched on Ramree Island on January 21, and the island was finally occupied during February. Airfields were rapidly built at Akyab and on Ramree Island to make it possible for the Fourteenth Army to be supplied by air in its drive toward Rangoon from the Irrawaddy.

In northern Burma the southward advance from Myitkyina, begun by Stilwell in October 1944, made slow progress, and it was not until December 15 that Bhamo was occupied. Sultan, who now had an American brigade (which incorporated the Marauders), a British division, and three Chinese divisions, pressed on and made junction with the Yunnan armies on the old Burma Road on Jan. 20, 1945. The road from Ledo to China was now clear, and the first convoy from India passed along it to reach Kunming on February 4. Work was immediately begun on extending the Ledo-Myitkyina oil pipeline to Kunming. Meeting with little opposition, for the Japanese were forced by the threat to Mandalay to withdraw southward, Sultan's forces occupied Lashio on March 7. Meanwhile, using Myitkyina as a staging post, the Air Transport Command had doubled the monthly air deliveries to China. With this increase and a road and pipeline from India, China was no longer isolated from her allies.

The Japanese sea communications with the Southern Regions, already precarious owing to the activities of the American submarine fleet, were completely severed when Leyte and Luzon in the Philippines were reoccupied in the winter of 1944-1945. The Japanese armies in the Southern Regions, forced to exist on the countries they had occupied and such reserves of war material as they had stored, withdrew divisions from outlying territories, including Burma, to reinforce Indochina, now open to invasion from the Philippines, and thus weakened their ability to defend the other areas.

By the end of February 1945, a fleet of river craft had been assembled on the Chindwin at Kalewa to supplement air supply and, with adequate supplies ensured, Slim began to cross the Irrawaddy in mid-February. The 4th Corps captured Meiktila by surprise on March 3, and shortly thereafter Mandalay was invested from both the north and the south. In a desperate attempt to stave off final defeat, the Japanese concentrated their remaining forces in Burma and launched a counteroffensive to recapture Meiktila; fierce battle raged throughout March, but by the end of the month Mandalay had been captured, and the Japanese had been thrown back with very heavy losses, their armies losing all cohesion. This offensive proved to be their last in Burma. Slim immediately resumed the pursuit toward Rangoon along both the main railway and the Irrawaddy. Toungoo was occupied on April 2 and Prome on May 2, and Pegu was reached on April 29. To ensure that Rangoon was occupied before the monsoon broke, an amphibious landing, preceded by a parachute drop, was made near the mouth of the Rangoon River on May 2, and the city, which had been hastily evacuated by the Japanese a few days before, was entered without opposition on May 3. The campaign for the reoccupation of Burma was now over, except for extensive mopping-up operations, and SEAC began to prepare for the invasion of Malaya. With the virtual end of the Burma campaign, all

the American and Chinese resources remaining in India and Burma were gradually transferred to China, and plans were made in Chungking for an offensive by 39 divisions to capture a port in eastern China in the fall of 1945.

The swift progress of the American offensive in the Pacific (see section 10, *War in the Central and Northern Pacific*) culminated in the capture of Iwo Jima in March and of Okinawa in June 1945. The Americans now had forward bases for an invasion of Japan, and the Japanese were forced to withdraw troops from Manchuria, Korea, and China to defend their homeland. In China, to forestall any amphibious landing, they began to withdraw toward its coast and concentrated their forces in the Canton area, the lower Yangtze Valley, and Shanghai, thus enabling the Chinese, with American assistance, to reoccupy many of the airfields in eastern China which had been lost the previous year.

Japan opened negotiations for peace on August 10 after atomic bombs had been dropped on Hiroshima and Nagasaki on August 6 and August 9. On August 14, she surrendered unconditionally. The USSR declared war on Japan on August 8 (effective August 9) and, using a massive force of three strong army groups, invaded Manchuria, Korea, southern Sakhalin, and, later, the Kuril Islands. The Japanese armies in Manchuria, reduced in size and weakened by the need to provide for the defense of the homeland, could offer little resistance, and when hostilities ceased on August 14, Russian troops were close to their objective, Mukden (now Shenyang) in Manchuria, had landed a force on the northeast coast of Korea, and had occupied Sakhalin.

In China the isolated Japanese armies also surrendered, and Hong Kong was freed. In the Southern Regions troops were sent to occupy Singapore, Bangkok, and Saigon early in September, and on September 9 the amphibious attack on Malaya took place as planned but under

British troops attack the enemy in a native basha (hut) in a banana grove. The dense vegetation is typical of the combat areas of the Burmese theater of war.

Imperial War Museum, London

peacetime conditions. The Japanese armies in the Southern Regions formally surrendered at Singapore on September 12. The long task of rounding up the Japanese forces and recovering the many thousands of Allied prisoners of war throughout the area then began.

War on the Mainland in Retrospect.—The Japanese were able to gain all their objectives in Asia in 1941–1942, for the United States was unready for war, and Britain, fighting single-handed in Europe, could not find the means with which to defend her interests in the Far East adequately. Thereafter the course of the war on the Asian mainland fell into two phases. The first, in 1942–1943, was one of comparative inactivity while the Japanese digested their conquests and organized their defenses and the Allies gathered their strength, overcame their grave logistical difficulties, and kept China in the war by air supply. During the second phase, in 1944–1945, the Allies launched an offensive to recapture Burma and drive a road through to China. The offensive succeeded, but before further operations could be mounted to liberate Malaya and other occupied territories, the war came to a sudden end as a result of the rapid American offensive across the Pacific to the very threshold of Japan and of the dropping of atomic bombs, which forced Japan to capitulate. It was thus the surrender of her wide-flung armies in Asia which followed, rather than their defeat in the field, that eventually freed the greater part of the Asian mainland from Japanese domination.

12. Developments in Naval Warfare

Naval developments in World War II may be divided into four categories: (1) carrier operations, (2) amphibious operations, (3) mobile logistics, and (4) antisubmarine warfare. The development that overshadowed all others was the task force system whereby both carrier and amphibious operations were conducted in the Pacific. Also of major importance was the development of the mobile logistics that enabled the task force system to be employed. In addition, the developments that resulted from the campaign against German submarines may have been particularly significant because of their relation to future naval warfare.

Task Force System.—During World War II the expression "task force" used in connection with fast carrier operations in the Pacific caught the imagination of the American people and became part of their language, though with a variety of meanings. In the working language of the United States Navy, however, "task force" is one of a group of terms employed in connection with a system of organization which it has evolved for managing its combat ships in order to make the most effective use of sea and air in modern, fast-moving warfare, while at the same time providing for the maintenance, support, and constant replenishment needed by these ships. In naval warfare it is the manned ship that fights, not the man himself. A combat ship functions

only at sea, but it must return to port at various intervals to prepare and replenish itself again for sea duty. It is therefore possible to separate in time the tactical employment from the logistics of a ship, its operation from its administration, and this separation is carried over into naval organizational structure in a manner not possible in land warfare.

The task force method of conducting naval warfare is a byproduct of what might be called the task-type organization of naval operating forces. In this method of organization a combat ship's captain actually works for two commanders. He is under the operational control of a task commander, who is responsible for completing some task within the Navy's mission; and is under the administrative control of a type commander, who is responsible for the ship's upkeep, supply, discipline, and (within certain limits) training. Broadly speaking, a task commander is concerned with functions of purpose, and he serves as operational commander of a composite force of ships suited to a particular purpose. A type commander is concerned with the functions of support, and he maintains the readiness of his ships, which are usually of one type, such as carriers, cruisers, or destroyers. He is an administrative commander and does his job primarily with such of his ships as are in port.

The task force organization of combat ships was best represented during World War II by the carrier task forces, which also included battleships, cruisers, and destroyers. Amphibious task forces were composed of amphibious ships of all types, as well as battleships for gunfire support, small carriers for air support, and destroyer types for antisubmarine protection. Replenishment task forces consisted primarily of tankers, ammunition ships, and salvage tugs, with a cruiser flagship and small carriers and destroyer types for protection. These task forces could be divided into task groups and task units, while the administrative commands retained the older designations of squadron and division. The task concept was expanded to the fleet level in 1944. The two task fleets in the Central Pacific were the Fifth and Third fleets: the Fifth Fleet conducted the operations against the Marianas, Iwo Jima, and Okinawa, while the Third Fleet assisted Gen. (later General of the Army) Douglas MacArthur in the recapture of the Philippines. The units that composed these fleets came from the pool of Central Pacific ships, which were assigned or withdrawn as operations required and the condition of the individual ships warranted. When ships were withdrawn from operational status, they reverted to the control of their type commander, whose headquarters were usually located with that of the commander of the Pacific Fleet. Ships newly commissioned or reverting to operational status after extensive repairs were assigned temporarily by the type commander to training commands, which specialized in preparing ships for combat. Such training was usually conducted outside of operational areas, although Japanese forces on bypassed Pacific islands provided targets for aircraft training.

Carrier Operations.—The task force system was most widely exemplified in carrier operations. The destruction of the battleships at Pearl Harbor in December 1941 made the capital ship of the United States Navy the carrier, with its main battery of manned striking aircraft carrying torpedoes and bombs and a defensive system com-

sisting primarily of fighter planes. Only the Japanese and United States navies developed carrier operations to a high degree. The technique of operating aircraft from carrier decks and the tactics of various aircraft types, especially the dive bomber, had been developed before the war and were similar in both navies. Usually the Americans initiated these developments, while the Japanese copied and perfected them.

As a capital ship, the carrier caused a revolution in naval tactics. As long as the gun remained the major weapon, the standard combat formation was the battleline, with light forces disposed on the engaged van and rear. When carriers first operated with the fleet, they took station on the unengaged side. As the manned airplane with its longer range replaced the big gun, the battle formation was changed to a circular one, with the carriers in the center, and other forces disposed around them to give them protection. United States formations were generally tight, with all the ships making tactical movements together in a task group that included four carriers. The Japanese operated in looser formations, and carriers with their attached ships conducted flight operations independently.

The primary striking carrier weapons in the United States Navy were the TBF Grumman Avenger, which could be used as a torpedo plane or as a level bomber, and the SDB Douglas Dauntless, a scout and dive bomber. The fighter that finally triumphed over the Japanese Zero was the Grumman F6F Hellcat. Japanese aircraft were also given identification names by the Allied forces. The famous Mitsubishi Zero fighters, for example, were called Zekes, while the long-range, two-engine Mitsubishi bombers were known as Bettys.

All American ships were equipped with aircraft and surface radar by the end of 1942, but radar did not come into general use in the Japanese Navy until late in 1943. The Japanese fought such major actions as the battles of the Coral Sea and Midway without it. United States fighter aircraft in these and subsequent engagements were directed against oncoming raids by fighter directors using radar, thereby enabling the fighters to meet enemy aircraft from 50 to 70 miles out. The extensive use of radar resulted in the establishment in United States ships of a combat information center (CIC), where all information received was analyzed and plotted and then relayed to the flag or commanding officer for his action. In some cases the officer in tactical command took his station in the CIC. It was surface radar that finally enabled the Americans to overcome the superiority of the Japanese in night actions.

Antiaircraft fire from United States ships early in the war was not effective, and enemy planes that were able to elude the United States fighter planes had good chances of making a successful attack. The variable-time (VT) or proximity fuze in antiaircraft ammunition, which was adopted in the Pacific in January 1943, changed this situation. An influence fuze, the VT was actually a small radar set that triggered the firing mechanism within 70 feet of the target in its destructive zone. At first it was restricted to naval actions, since it was feared that its use against land targets would result in its discovery by the enemy. In 1944, VT fuzes were employed successfully against V-1 flying bombs, as well as by ground forces in the Battle of the Bulge, the importance

of which was considered to justify the possibility of discovery. Exploding a short distance above the ground, this fuze made the foxhole valueless as a safeguard for the foot soldier.

Amphibious Forces.—All ground operations in World War II began with amphibious assaults. The first, made in August 1942 at Guadalcanal, was a defensive operation designed to seize the island in order to halt the Japanese thrust into the Solomons. It was followed in November by landings in North Africa. Amphibious operations in Europe included the assault on Sicily in July 1943, the cross-Channel invasion of Normandy in June 1944, and the movement into southern France in August. These were all primarily operations intended to seize beachheads from which large forces would subsequently break out for land campaigns. In the Pacific, however, one amphibious operation necessarily followed another. Amphibious operations in the Southwest Pacific were made at frequent intervals in relatively short shore-to-shore movements, while in the Central Pacific they involved large lifts over long distances. The assaulting forces in Europe were Army troops, whereas in the Central and Southwest Pacific both Marine and Army forces were employed. A greater amount of improvisation was necessary in the Southwest Pacific than in the Central Pacific, since naval elements were smaller and the theater generally received lower priorities for amphibious equipment.

Because of sound doctrine and proper landing equipment, all United States amphibious operations in World War II were successful. The doctrine had been developed by the United States Marine Corps in the two decades before the war, under the shadow of the British failure at Gallipoli in World War I. It was set forth in a *Manual for Landing Operations*, which attempted to define (1) command relationships; (2) naval gunfire support; (3) air support; (4) ship-to-shore movement; (5) the securing of the beachhead; and (6) logistics. The basic doctrine outlined in this manual withstood the long trial by fire in war without fundamental changes.

The reason for this success was without doubt the provision of adequate craft for the landing of assault units and for logistic support over the beaches until proper port facilities could be built. The landing craft were of two basic types: (1) ships and boats that had the ability to beach without swamping, and also to withdraw; and (2) amphibians. Hulls of the first type were designed so that the craft grounded on only a small area forward. In withdrawing, the slipstream from the protected propeller washed away sand in the grounded area, thus releasing the craft from the beach. A ramp forward facilitated the rapid discharge of passengers and cargo. The smaller types, which were carried aboard transports, were designed by Andrew J. Higgins, a New Orleans boatbuilder. These were the LCPV (landing craft, vehicle and personnel) and the LCM (landing craft, medium), which were capable of transporting a tank. A larger type, designed to proceed under its own power to the designated area, was of British design: it included the LST (landing ship, tank) and the LCI (landing craft, infantry). The LCI subsequently evolved into a close-support gunboat type, while the LST with its ample tank deck became one of the most useful crafts in the war, employed in a range of logistic services far beyond those originally intended. LST's were employed as hospital

Wide World

ships, barrack ships, tenders for small landing craft, floating machine shops, and issue ships. When they were forced to beach out from the shoreline because of shallow gradients, they could carry pontoon causeways with them. Intermediate types between shipboard craft and the LST were the LSM (landing ship, medium), a small LST, and the LCT (landing craft, tank), which was essentially a powered barge.

The second basic type of landing vehicle, the amphibian, could be propelled both in water and on land. The caterpillar type, invented by Donald Roebling, was able to cross the shoals and beaches of the Pacific. Two models were employed: the personnel carrier, LVT (landing vehicle, tracked), with a ramp in the rear, which allowed troops to debark quickly under some cover; and the LVT (A), or armored amphibian, which was actually an amphibious tank. The Army developed a vehicle of its own, code named the DUKW, an amphibious truck with a propeller drive in the water and a wheeled drive on land.

Special types of large amphibious ships also were built, mainly for the transport and support of landing craft, such as the LSD (landing ship, dock) and the LSV (landing ship, vehicle), an amphibian carrier. The assault transport or cargo ship carried as many as 9 LCM's and 26 LCVP's.

An important element in an amphibious operation was the shore party, which included the labor for quick unloading under difficult conditions. In the Central Pacific, where troop space in large overwater movements was limited, such labor was performed by a small number of specialized service troops augmented by reserves, although the latter were often called into combat when the unloading phase was at its most critical stage. In the Southwest Pacific the engineer special brigade was employed; it had regiments consisting of a boat battalion and a shore battalion, ably officered and with needed service troops attached.

See also AMPHIBIOUS WARFARE.

Mobile Logistics.—The major carrier and amphibious operations in the Pacific could not have been carried out without a highly developed system of mobile logistics. By means of this system ships of the Pacific Fleet were able not only to remain indefinitely in forward areas adjacent to enemy territory, but also to cruise at sea for long periods in readiness for combat. Such mobile logistics enabled combat ships to receive fuel and

other needs from service ships either while under way or at anchorages near operating areas. Advanced base facilities were maintained afloat at all times, and techniques were developed for transferring fuel, ammunition, stores, and personnel at sea, thus freeing combat ships from the necessity of returning to port at frequent intervals.

The maintenance of logistics afloat had two advantages in addition to keeping combat ships at sea: (1) Service craft could move forward relatively easily either under their own power or by towing. (2) Better storage and handling facilities and more accurate inventory control were available than in primitive shore areas. The disadvantage was the great demand for ships.

The primary requirement of a floating base is a large anchorage affording good holding ground and capable of being protected from submarine attack. Adjacent land is required only for fighter strips, recreation areas, and those naval facilities that can perform their functions better on shore. The atolls and islands of the Central Pacific provided such areas, and in the advance across the ocean United States naval forces used the anchorages at Majuro, Eniwetok, and Ulithi. Earlier in the war floating bases were established in conjunction with shore facilities at Nouméa in New Caledonia, Espiritu Santo in the New Hebrides, and Manus in the Admiralty Islands. Afloat bases were later located at Samar in the Philippines and the Kerama-retto near Okinawa.

From its beginning the United States Navy had a tradition of operating with afloat logistics, since historically it was a navy without proper bases even in its own country. Nevertheless, the immensity of the logistic problem in a cross-Pacific war had not been realized in prewar planning. Various reasons may be advanced for this failure, the most logical being the discontinuance of the study of logistics at the Naval War College and the fact that fleet problems could not be made broad enough for the impact of logistics to be felt. As a result, major problems had to be solved just before or during the war. A logistic structure had to be improvised, and the reason that it was done so quickly and so well was that abundance could cover mistakes.

The first conception for providing logistics for the fleet was the establishment of advanced base units on shore. Such units were specially organized in the United States with equipment packaged for erection in forward areas. Designated as Lions (major bases), Cubs (minor bases),

and Acorns (aviation bases), they included construction battalions, boat pools, harbor defense units, repair facilities, and other functional components. These had to be set up in advanced areas and could not readily be moved forward as the war advanced. Cubs were established at Espiritu Santo and Gaudalcanal, and a Lion was set up at Manus. As the war moved closer and more rapidly toward Japan, this conception was largely abandoned.

With the capture of the Marshall Islands in February 1944, the practice of afloat logistics came into its own. Most of the service ships at Pearl Harbor were transferred to Majuro to form Service Squadron 10. This force was a medley of floating equipment, including repair ships, floating dry docks, tenders, provision ships, ammunition ships, hospital ships, station tankers, lighters, tugs, floating cranes, distilling ships, survey ships, cold storage ships, and floating barracks. The largest piece of floating equipment used during the war was the ABSD (advanced base sectional dock), capable of lifting 90,000 tons and docking any ship in the Pacific. Any of its sections (a maximum of 10) could be towed forward separately and be docked by the others.

The second element in mobile logistics during the war was afloat replenishment, which enabled ships to remain at sea longer than steam vessels had ever done before. The continuing requirement was fuel oil, of which a combat ship always required sufficient for battle. The practice in the Pacific therefore was to fuel at sea every three to five days. The technique of such fueling, which had been developed in the United States Navy before World War I, did not change essentially thereafter. Two ships would steam alongside each other, one at a slightly greater speed so as barely to tow the other, and both under rudder control. Fuel would be delivered through flexible hoses that were kept suspended and out of the water between the two ships by booms and running gear. The British Navy, having operated through two world wars largely in the North Sea and with bases elsewhere in the world, had not developed an efficient technique of fueling at sea, and the Royal Navy carrier force that joined the Pacific Fleet in 1945 had to fuel by the slow method of towing in tandem with a floating hose between the two ships. The major replenishment need after fuel was ammunition, for magazine space in combat ships was limited. In the later stages of the war provisions and special stores, replacement aircraft, and even personnel also were transferred at sea.

The replenishment force operated as Service Squadron 6 during the Iwo Jima and Okinawa campaigns. While its composition varied with conditions, it was generally composed of a light cruiser flagship, about 16 tankers, 4 ammunition ships, 4 fleet tugs or salvage ships for towing crippled ships from the battle area, 2 aircraft transports, provision ships as required, and protective escort carriers and destroyer types.

The realization of the importance of mobile logistics was illustrated in the Okinawa campaign by the seizure before the assault landing date of the Kerama-retto, an island group west of Okinawa that had a good anchorage. Mobile logistics was not nearly as essential for ground forces and land-based forces in the Pacific as for naval forces, but it was found that, where sufficient shipping was available, it was preferable to retain supplies afloat until they were needed

ashore. The transfer forward of army bases from the New Guinea coast after the recapture of the Philippines necessitated the withdrawal of a large number of LST's from combat operations.

To move men and materials across two oceans required a complete reorganization of the American merchant marine and a tremendous shipbuilding program. In February 1942, the War Shipping Administration (WSA) was established to provide shipping needs for the war economy and the armed services. Two standard types of cargo ships were built rapidly and in quantity by the American shipbuilding industry: the 10-knot Liberty ship and, later, the 15-knot Victory ship. These ships were then outfitted and manned by shipping companies but were operated by the WSA.

Antisubmarine Operations.—Insofar as future warfare was concerned, the most important naval developments of World War II may have occurred in the North Atlantic, where the struggle for survival of Great Britain was won before the United States offensive in the Pacific began. The victory over the German submarine was mainly the result of British efforts, the United States contribution consisting primarily of mass production processes.

Karl Doenitz (Dönitz), the German admiral in command of submarines, was one of the toughest naval antagonists that the Allies met during the war. He believed that Germany could win only by sinking an average of 750,000 tons of Allied shipping monthly, and his strategy was to keep his submarines moving to areas where sinkings were easiest to obtain. Against convoys he preferred to use heavy concentrations of U-boats known as wolf packs in continuous attacks, directing them individually from his headquarters ashore. The weakness in this method of control was the amount of two-way radio traffic required: Allied high frequency direction finders were able to locate German submarines with considerable accuracy. Wider convoy routing and better antisubmarine precautions in distant areas forced Doenitz to return to the shipping lanes of the North Atlantic, and it was there that the battle was finally settled in the summer of 1943.

The German submarines were defeated by the Royal Navy's battle-scarred escorts and by aircraft of the Royal Air Force (RAF) Coastal Command under the operational control of the Admiralty. British scientists also made contributions to this victory, two of them major: microwave radar and operational research on antisubmarine warfare methods. The British success can be attributed to radar; sonar (asdic in British terminology), high frequency direction finding; the escort carrier; antisubmarine support groups of destroyers, which reinforced the escorts of convoys under attack; and the extension of land-based airpower across the Atlantic by the employment of B-24 Liberators. The principal United States contribution was the escort carrier, used to cover the areas in the mid-Atlantic that land-based aircraft did not reach. Escort groups, consisting of a small carrier and about 4 destroyer types, began operating in June 1943. They were especially successful in locating submarine refueling rendezvous. Hunter-killer groups of this type are still retained in the operating forces of the United States Navy.

The technological advance that proved most

Wide World

fruitful for the British in the antisubmarine campaign was microwave radar. German submarines while on the surface were able to detect enemy use of long-wave radar and could submerge in time to avoid attack. They failed, however, to discover that microwave radar was being employed against them until 1944, with the result that surface vessels were able to approach close enough to a submarine before it submerged to get it on the sonar. Coastal Command aircraft were eventually fitted with this type of radar. Used in conjunction with the Leigh light, a powerful searchlight controlled by the radar set, it was able to surprise surfaced submarines, which could be attacked before they submerged.

Late in the war antisubmarine ordnance was radically improved by the introduction of a projectile to augment the depth charge. The mount, called a hedgehog, threw 24 missiles over the bow of the attacking ship. Since the missiles exploded only after one of them had struck the submarine, there was no explosion in an unsuccessful attack to disturb the sonar search and give the submarine time to escape.

Because sailing in convoys delayed shipping, vessels capable of making 15 knots and over sailed singly, with the expectation that faster turnarounds would compensate for submarine losses. Pressure was brought on the Admiralty to sail 13-knot ships singly as well, but this change proved a mistake, and the 13-knot convoys were reestablished in May 1941.

Improved convoy efficiency was finally attained through operational research. By analytical studies of attacks, British scientists discovered that the number of sinkings bore no relation to the size of the convoy and depended only on the number of attacking U-boats, on whether the convoy had air escort, and, when it did not, on the number of surface escorts. Convoys were therefore increased in size from 32 to 54 ships, providing both better protection and faster delivery of cargoes. Air escort during daylight was found to decrease losses by an additional 64 percent, making sinkings negligible.

Late in the war the Germans developed the snorkel, by which a submarine could both cruise and charge batteries underwater with only the extension of this breather pipe exposed. It was perfected too late to affect the German submarine effort and require antisubmarine methods to counter it. But the problem of countermeasures remained with the postwar nuclear-powered submarine, a true submersible able to remain underwater constantly and cruise at great depths with high speed.

JOHN D. HAYES

Rear Admiral, United States Navy (Retired).

13. Developments in Air Warfare

Doctrines of Command and Employment.—Aviation had little effect on the outcome of the surface battles of World War I because it was still in its developmental infancy. In each major nation after the war, however, civilian and military leaders studied the ideas of such men as Britain's Sir Hugh Trenchard, America's William Mitchell, and Italy's Giulio Douhet. The nations that were to be the major air adversaries of World War II developed plans for organization and aerial equipment which reflected their national objectives and their basic concepts of war.

The Royal Air Force (RAF) of Great Britain was formed on April 1, 1918, by the union of the Royal Flying Corps and the Royal Naval Air Service. Although the British Navy later recovered control of its aviation units, Britain continued to accord aviation coordinate status with land and sea forces. In its rearmament programs after 1936 it felt compelled to emphasize the development of air defense forces to meet the challenge of Nazi Germany's Luftwaffe.

Despite frequent demands for a unified air force, the United States continued to maintain separate Army and Navy air forces, but the organization of the Army Air Forces on June 20, 1941, and the establishment of air representation on the United States Joint Chiefs of Staff gave aviation a status practically coordinate with that of the older services. As a result of war experience, War Department Field Manual 100-20, *Command and Employment of Air Power*, which was issued on July 21, 1943, stated: "Land power and air power are coequal and interdependent forces; neither is an auxiliary of the other." United States Air Corps leaders were able to obtain the development of long-range heavy bombers because of the requirements of hemispheric defense, but they also gave attention to the procurement of aircraft designed to support ground forces.

Although the Luftwaffe was established as an independent equal of the German Army and Navy in 1935, the Nazi high command viewed air forces as valuable chiefly for supporting blitzkrieg ground assault campaigns. The Luftwaffe was equipped chiefly with fast fighters, twin-engine bombers, and transport planes. The other Axis partner in Europe, Fascist Italy, in 1923 created a separate air force that professed to follow Douhet's teachings. Prewar feats of picked Italian aircrews and special airplanes enhanced Benito Mussolini's reputation, but the Italian Air Force had almost no modern aircraft when it went to war in 1940. A few Italian air units

later served with the Luftwaffe when Germany took over military operations in the Mediterranean area.

When World War I ended, France possessed the world's largest and most virile air force, but its strength was eroded by mismanagement at high levels. During the 1930's, French economic mobilization policy did not support the country's foreign policy, and the General Staff chose to develop the Maginot Line and the navy at the expense of aircraft and tanks. France was probably superior to Germany in the caliber of its aircrews and in individual aircraft characteristics in 1939, but the Luftwaffe held an imposing quantitative superiority, which was increased by the dispersion of the French Air Force. In the air-ground battles of 1940 the French air arm inflicted heavy damage on German air and armored forces, but it was too small and was soon destroyed as a fighting force.

Viewing aviation as a supporting force for surface operations, Japan maintained completely separate and seldom cooperative army and navy air forces. Even in the final months of the war, when the home islands were under air attack, the two air arms had separate aircraft warning systems, and each attempted to protect the targets which it judged to be most important. Except for the courage and patriotism of the fliers who gave their lives in futile Kamikaze (q.v.) attacks, Japan contributed little to the development of air-power experience during the war.

The USSR's air forces were organized into a relatively unimportant naval air force and the Soviet Air Force, which both belonged to and was assigned to assist the Soviet Army. As a support force, the Soviet Air Force developed heavily armored fighters and medium bombers. In 1942, Joseph Stalin organized an independent air force, known as the Long-Distance Flying Command (ADD), but it did not receive equipment suited to its mission. By Anglo-American standards the ADD was a force of medium bombers and twin-engine transports.

Strategic Bombardment.—In its essentials the concept of strategic bombardment was best stated in Douhet's writings. This concept visualized a defensive role for surface forces, an aerial offensive designed to secure command of the air, and the aerial destruction of an enemy's capacity to support surface forces and its will to continue the war. Douhet believed that command of the air would be established by attacks against enemy aviation facilities and not through aerial fighting. He therefore advocated development of a "battle plane" capable both of defending itself in the air and of destroying hostile ground objectives.

Although the Luftwaffe was not designed for strategic air warfare, Adolf Hitler elected to commit it to the Battle of Britain on Aug. 8, 1940. The Nazi plan was to gain air superiority by destroying the RAF Fighter Command and to employ the German bomber force to soften British coastal defenses, transportation facilities, and population centers in preparation for a combined sea and airborne invasion of southern and southeastern England. Aided by newly developed radar, the British fighter force proved superior to German bombers, which were inadequately armed and lacked the ability to carry heavy loads of bombs. A series of vacillating decisions by the Luftwaffe commander, Hermann Goering (Göring), also prevented the numerically superior German Air Force from achieving a decisive concentration of

Striking deep into enemy territory, American bombers make a carefully aimed attack on the Focke-Wulf aircraft plant in Marienburg, East Prussia, on Oct. 9, 1943.

force against any single objective. By December 1940, the Luftwaffe had failed to accomplish its strategic mission and had suffered heavy losses. In its subsequent campaigns against the Soviet Union, it continued to lack long-range bombers and was powerless to prevent the Russians from rebuilding an air force at factories and bases beyond the Ural Mountains. According to the United States Strategic Bombing Survey, the first factor in the ultimate defeat of the German Air Force was that: "The German Air Force was originally designed for direct support of ground operations, and a lack of a long-range bomber force proved a grave strategic error."

Because of the national emphasis on air defense, the RAF Bomber Command was weak at the beginning of the war and was unable to undertake strategic bombing before May 1940. The buildup of American Army Air Forces heavy bombers in Europe was delayed by conflicting requirements of the Allied land campaign in North Africa. Not until Jan. 21, 1943, could the Anglo-American Combined Chiefs of Staff order a combined bomber offensive designed to attain "the progressive destruction and dislocation of the German military, industrial and economic system, and the undermining of the morale of the German people to a point where their capacity for armed resistance is fatally weakened." As implemented thereafter, the combined bomber offensive employed RAF bombers that flew at night chiefly against area targets and American bombers from Great Britain and Italy that made daylight precision-bombing attacks. Contrary to original expectations, American bombers required fighter escorts to prosecute sustained attacks against heavily defended targets, but early in 1944 a combination of attacks against aircraft facilities and of aerial battles established Allied air superiority over Germany.

Many airpower proponents consider that World War II neither proved nor disproved the validity of strategic air doctrines, since the war was conducted as a series of interdependent air, ground, and naval campaigns. In any assessment

of the results of the combined bomber offensive against Germany, it is certainly important to note that it was related to the Allied ground campaign, which began with the invasion of Normandy on June 6, 1944. Of the 2,700,000 tons of bombs dropped against Germany, only 28 percent fell before July 1 of that year. Only after the successful Allied invasion were the heavy bombers free to attack strategic targets in Germany in full force. Utilizing its tremendous economic potential and displaying good ability to repair and disperse its factories, Germany actually increased its war production during the months of the Allied air attack. War requirements multiplied even more swiftly than production, however, with the result that beginning in December 1944 all sectors of German economic life were collapsing. "The German experience," stated the United States Strategic Bombing Survey, "suggests that even a first-class military power—rugged and resilient as Germany was—cannot live long under full-scale and free exploitation of air weapons over the heart of its territory." After a later and more exhaustive study, the British historians Sir Charles Kingsley Webster and Noble Frankland concluded in *The Strategic Air Offensive Against Germany, 1939–1945* (vol. 3, p. 310, London 1961): "... both cumulatively in largely indirect ways and eventually in a more intimate and direct manner, strategic bombing . . . made a contribution to victory which was decisive."

In the war against Japan, carrier-based aircraft of the United States Pacific Fleet eventually joined the strategic air campaign, but the United States Twentieth Air Force contributed the vast preponderance of the strategic bombing effort against the Japanese home islands. With a limited economy crowded into a few industrial cities and without adequate air defenses, Japan was highly vulnerable to air assault. Nevertheless, strategic bombing had to await the deployment to combat of the new B-29 aircraft, which had a range long enough to reach Japan from available bases. Hurred into combat from airfields in western China, the Twentieth Air Force's 20th Bomber Command initiated strategic air attacks against Japan on June 15, 1944, but the distance was too great and logistical support too scarce for the B-29's when flying from China. Utilizing newly built bases in the Mariana Islands, B-29's of the 21st Bomber Command launched sustained air attacks against Japan on Nov. 24, 1944. During the period March 9–June 15, 1945, these planes flew at night to prosecute heavy incendiary attacks against six principal Japanese urban industrial concentrations. Effectively blockaded by American submarines and under heavy air attack, Japan's leaders were ready to sue for peace (though not unconditionally) in May 1945, well before the USSR's entry into the Pacific war and the employment of United States atomic bombs against Hiroshima and Nagasaki (qq.v.) on August 6 and August 9. "It seems clear," stated the United States Strategic Bombing Survey, "that air supremacy and its later exploitation over Japan proper was the major factor which determined the timing of Japan's surrender and obviated any need for invasion."

Tactical Air Support for Ground Warfare.—

Other nations had planned to employ aviation in support of their ground forces, but the techniques of the Luftwaffe in Poland, Norway, the Low Countries, and northern France during 1939 and 1940 established a model of effectiveness. Or-

ganized into air fleets (*Luftflotten*) and air corps (*Fliegerkorps*), the Luftwaffe jealously guarded the integrity of its air units, but it made every effort to perform preplanned missions in support of the blitzkrieg. (Only reconnaissance was attached directly to ground units, and this branch of aviation was repossessed by the Luftwaffe in 1942.) Rarely remaining at one airfield more than a few days, the *Fliegerkorps* shifted the mass of their dive bombers and fighters to attack critical targets on any ground front. The stages of the air attacks included strikes against hostile aircraft and enemy airfields, the enemy's communications and main headquarters, and then the enemy's beaten and retreating troops. These corps performed very effectively on the narrow front characteristic of ground operations in western Europe. At the beginning of the campaign against the Soviet Union the German Air Force again achieved striking successes, but the distances soon proved too great and the force available too small. Moreover, the Soviet Air Force rebuilt its strength and countered German blows with telling effect. The Luftwaffe not only was overextended, but also was required to devote most of its efforts to the close support of German ground forces, with a consequent reduction in the effort that could be applied to counter air force and interdiction operations.

In the early campaigns in Europe an RAF component was attached to the British Expeditionary Force, and individual squadrons were often attached to divisions and corps. In January 1943, the United States 12th Air Support Command in North Africa was similarly attached to the United States 2d Corps. Such arrangement negated the inherent flexibility of aviation, and centrally controlled Luftwaffe units easily overwhelmed divided Allied air squadrons. Recognizing that "penny packets" of aviation were ineffective, Gen. (later Field Marshal) Sir Bernard Law Montgomery (later 1st Viscount Montgomery of Alamein), commander of the British Eighth Army in North Africa, acknowledged Air Vice Marshal (later Air Marshal Sir) Arthur Coningham as his equal and permitted the Desert Air Force to be employed as a centrally controlled force. On July 21, 1943, the United States War Department officially accepted this coequality of ground and air forces and provided that the tasks of the new tactical air forces, which were designed to cooperate with ground armies, would be to gain air superiority, to prevent the movement of hostile troops and supplies, and to provide close air support to ground troops. This pattern of air employment was tested in Italy and elaborated in the all-out ground campaigns in Europe after June 1944.

Even though the USSR continued to consider aviation as an auxiliary to ground armies, the actual employment of the Soviet Air Force was similar to that of the Americans and the British. As a rule, one air army served each front (army group) and operated according to the battle plan of the front commander. The Soviet Air Force recognized the tasks of air superiority, isolation of the battle area, and close support. Long-range missions of the ADD were usually coordinated with the requirements of the ground battle.

In the jungle and island battles of the Pacific the broad outlines of tactical air force employment were not unlike those of Europe. Ground invasion troops in these theaters, however, generally lacked sufficient organic artillery, with the result that close air support of ground forces was

f added importance. With a long tradition of ground support, which dated back to the Nicaraguan intervention of 1926-1933, United States Marine airmen developed (especially in the latter stages of the Pacific campaigns) communications, command, and employment techniques that enabled them to give excellent close air support to friendly ground troops.

Airborne Assault and Air Transport.—For a nation that had extensive civil experience with air transport and had pioneered in the military application of airlift by ferrying Gen. Francisco Franco's Moroccan troops to Spain in 1936, Germany was strangely ambivalent in the field of transport aviation. The Luftwaffe never consolidated the management of transport under a single chief, and the standard Ju-52 transport fleet not only was used for airlift but provided a substantial proportion of the aircraft employed in Luftwaffe training programs. In operations that proceeded according to schedule, Luftwaffe air transport machinery worked well, as was demonstrated in the employment of air-dropped and air-landed troops in Norway and the Netherlands in 1940 and in the capture of Crete in the spring of 1941. By the winter of 1942-1943, however, German air transport forces were exhausted in a futile effort to resupply the besieged ground armies at Stalingrad (now Volgograd).

At the outset of the war the Soviet Union probably intended to make extensive use of elite airborne troops, but these forces were soon destroyed in ground battles, and such transport aircraft as remained were usually employed in resupplying guerrilla forces. One of the chief missions of the ADD was to fly nocturnal supply drops to partisan troops in forward areas.

The Anglo-American organization of airlift forces placed central control of most such units under a troop carrier headquarters, which could employ the transport planes either for airlift or for air assault operations. Allied airborne assaults accompanied invasions in North Africa in November 1942, in Sicily in July 1943, in Normandy in June 1944, in southern France in August 1944, in the Netherlands in September 1944, and across the Rhine River in March 1945. The First Allied Airborne Army, which commanded both airborne divisions and troop carrier wings, managed the two last-named operations. In the Pacific theater smaller regimental-sized air assault operations were conducted at Nadzab, New Guinea, in September 1943 and at Tagaytay Ridge and Corregidor in the Philippines in February 1945. Both aerial resupply and air assault operations were vitally important under jungle warfare conditions in the recapture of Burma, the most striking single operation being Operation Thursday, the fly-in of Maj. Gen. Orde C. Wingate's Special Force into central Burma in March-April 1944.

When not employed in air assault operations, British and American troop carrier forces in all theaters hauled high priority supplies to forward airfields and evacuated sick and wounded men to rear-area hospitals on their return trips. In each Anglo-American theater of war the allocation of cargo space was managed by some form of central air transport control agency, which set priorities in terms of the immediate requirements of the theater.

Transport developments were almost entirely American. The Army's Air Transport Command reached from the United States into every combat theater

with scheduled flights, while the Naval Air Transport Service centered its operations in the Pacific. Flying the "hump" route across the Himalaya, the Air Transport Command's India-China Division delivered critically needed supplies to otherwise inaccessible China. On return trips to the United States both Army and Navy air transport planes brought sick and wounded men to hospitals near their homes. Air Transport Command crews also ferried replacement aircraft to combat air forces in various theaters.

Science and Air Warfare.—"Wars are fought with weapons based on fundamentals discovered during the preceding years of peace," wrote Dr. Theodor von Kármán in 1945. During World War II tremendous new scientific developments—electronics, jet propulsion, missiles and rockets, and nuclear weapons—influenced the conduct and potential of air warfare. The scientific fundamentals of each of these developments were known to all combatants well before the war, but their adaptation to military purposes depended on the initiative and productive capabilities of the belligerent nations.

The working principles of the branch of electronics known as radar (*radio detection and ranging*) were well understood in the early 1930's in the United States, Great Britain, and Germany. Only the British, however, expedited the construction of a chain of radar early warning stations, which enabled an inferior force of RAF fighters to meet and defeat superior numbers of the Luftwaffe in the Battle of Britain. Radar facilitated offensive fighter control and accurate antiaircraft artillery direction, thereby reducing the ability of bombers to reach their targets. On the other hand, additional developments in radar enabled aircraft to perform precision bombing at night or in bad weather, thus increasing the capabilities of offensive aviation. Every phase of air operations also demanded the utmost development of other forms of electrical communications, and by the spring of 1945 about 12.5 percent of United States Army Air Forces personnel was assigned to some phase of electronics activity.

One of the almost inexplicable puzzles of the war was the fact that early in the conflict Germany had air weapons within its grasp that might have redressed its growing aerial inferiority, and yet its Nazi masters failed to pursue their development. Arrogant after the defeat of Poland, Hitler refused to order full mobilization of Germany's economic potential for war until it was too late, and in 1940 he severely curtailed the development of new weapons that could not soon be available for combat. As a result of low development priorities and Allied bombing attacks, the Germans did not begin to employ their V-1 and V-2 missiles until June-September 1944, when the war was entering its final act. Because of indecision as to priorities and Hitler's insistence that the plane must carry bombs, the Me-262 jet fighter was not put into series production until November 1944. The operational employment of this new jet aircraft (superior by far to any Allied fighter) was too late to have any decisive influence on the air war.

Before the war strategic air warfare enthusiasts had overestimated the effect of air ordnance on urban and industrial targets. They had assumed erroneously that air attacks would easily break an enemy people's will to continue a war. Both in Europe and in Japan repeated air at-

tacks and many tons of conventional bombs were required to neutralize war production facilities. A prior establishment of air superiority had proved necessary to the prosecution of effective strategic bombing attacks. Unknown to many air leaders, the United States began to explore the possibilities of nuclear fission weapons shortly after Dr. Albert Einstein informed President Franklin D. Roosevelt on Aug. 2, 1939, that such weapons seemed practicable. Headed by Maj. Gen. (later Lt. Gen.) Leslie R. Groves, the Manhattan Engineer District produced the Hiroshima and Nagasaki weapons dropped by the Army Air Forces' 509th Composite Group in August 1945. The detonation of these first nuclear bombs not only hastened Japan's decision to surrender, but also represented a "quantum jump" in strategic air capabilities, which appeared fully to substantiate the Douhet concept of strategic bombardment. How these new and terrible weapons—which ultimately would be deliverable with little or no warning by intercontinental jet bombers and ballistic missiles—were to be utilized would be the complex problem facing military strategists in the years following World War II.

14. Diplomatic History

The history of diplomacy in World War II naturally unfolds in three major divisions: the first is the story of the expansion of the war from 1939 through 1941; the second describes the period of transition from 1941 through 1943, when the Axis powers exploited their conquests but also suffered reverses; and the third tells of the Allied search for agreement on postwar policies, producing rising tension within the coalition as it approached victory, 1943–1945.

EXPANSION OF THE WAR: 1939–1941

Poland, the Baltic States, and Scandinavia.—The Nazi-Soviet cooperation that had enabled Adolf Hitler to launch World War II was strengthened in the first phase of that conflict. On Sept. 17, 1939, Soviet forces moved into Poland, and on September 28 the German and Soviet foreign ministers, Joachim von Ribbentrop and Vyacheslav M. Molotov, revised the terms of the Nazi-Soviet Pact of August 23. The USSR conceded to Germany control over a slightly larger portion of Poland, and in exchange Germany recognized a Soviet sphere of influence in Lithuania as well as in Estonia and Latvia. The new German-Soviet frontier through Poland approximated the one generally known as the Curzon Line (q.v.). A Polish government in exile, established first in Paris and later in Angers, moved to London in 1940. There it organized émigré troops for the Allied cause and endeavored to promote the revival of a large Polish state after the war. Meanwhile, Joseph Stalin did not delay in collecting the other territories that Hitler had allotted to him. On Sept. 28, 1939, under Soviet military pres-

sure, Estonia signed a nonaggression pact granting the USSR naval and air bases. Similar concessions were won from Latvia on October 5, and from Lithuania on October 10.

The Finns caused Stalin greater difficulty. On October 12, the USSR offered to trade Soviet territory for strategic Finnish areas, but negotiations were broken off on November 9, and on November 30 the Soviet Army struck at Finland. The republic's stubborn resistance aroused much sympathy in the West. Great Britain and France considered intervention, the League of Nations expelled the USSR, and Americans discussed the severance of diplomatic relations with the Soviet Union. On March 12 however, before any assistance materialized, the Finns were forced to accept Soviet peace terms. As shown in Map 3, the USSR acquired the entire Karelian Isthmus, islands in the Gulf of Finland, territory northeast of Lake Ladoga, and a strip of central eastern Finland, as well as a 30-year lease on the Hangö (Hanko) Peninsula for use as a naval base and transit rights to Sweden and Norway.

In the meantime, in February and March, Anglo-French diplomacy sought unsuccessfully to win Norwegian and Swedish approval of a proposed Scandinavian front. But it was Germany rather than the Allies that opened the Scandinavian campaign, on April 9 launching simultaneous attacks on Denmark and Norway without diplomatic preliminaries. Within hours the Danish cabinet and king agreed reluctantly to German occupation of their country. Britain and France sent troops to Norway, but the last of the Allied forces were evacuated on June 8. Organized Norwegian resistance ceased, and the king and cabinet set up a government in exile in London.

German Mastery over Western Europe.—Until May 1940, the war in the west was peculiarly inactive. Addressing the Reichstag on Oct. 6, 1939, Hitler stated that the acquisition of colonies was his only remaining ambition. While vowing that the "Poland of the Versailles Treaty will never rise again," he proposed a peace conference. The response of Premier Édouard Daladier and Prime Minister Neville Chamberlain was cold. During the Polish campaign and even while making peaceful overtures, Hitler was planning attacks on France, Luxembourg, the Netherlands, and Belgium. When German forces drove into these nations on May 10, Berlin tried to persuade the Low Countries to accept German protection of their neutrality. The German diplomatic overtures failed, but German military success was swift. Luxembourg fell in a day, and the Netherlands capitulated in five days. Meanwhile, the Dutch royal family and cabinet left for London to form a government in exile, which thereafter concerted its policy with that of Great Britain and the United States for the protection of its possessions overseas. Belgium capitulated 18 days after the attack of May 10. Its king, Leopold III, surrendered against the advice of his ministers with only a few hours' notice to the British and French, and it was left to the Belgian premier to establish a government in exile.

In London, Winston Churchill had replaced Chamberlain as prime minister on May 10, but for the moment this step failed to improve Anglo-French fortunes. Virtually all of the British troops in France, as well as some French

and Belgians, were evacuated from Dunkerque by June 4. Meanwhile, the Germans advanced across northern France. They entered Paris on June 14. Premier Paul Reynaud resigned on June 16, and the next day his successor, Marshal Philippe Pétain, sought an armistice. The French accepted the German armistice terms at Compiègne on June 22. The northern and western half of France, including the entire Atlantic coast south to the Spanish frontier, was to be occupied by Germany. The French Fleet was not permitted to join the British to continue the war, but was to be demobilized and disarmed. Approximately 1,500,000 French prisoners of war were to remain German captives—hostages for the good behavior of France—until the end of the war. Although Free French leaders would soon rally around Gen. Charles de Gaulle in London and work with the Allies, the pliant government of Pétain continued to function in France, establishing itself at Vichy because Paris was in the zone of German occupation. The armistice left Hitler in control of Europe from the Vistula River to the Atlantic Ocean and from the Pyrenees to the Arctic Circle.

Intervention of Italy.—Two days after the ceremony of June 22 at Compiègne, an emptier one was staged in Rome, giving Benito Mussolini the right to occupy a tiny area in southeastern France and creating a demilitarized zone 50 kilometers wide on the Italian frontier. The duke's meager reward matched his contribution to the victory over France. In 1939 he had avoided entering the conflict. Now, on June 10, 1940, with French defeat assured, he had declared war on France and Great Britain with the approval of King Victor Emmanuel III. His 32 divisions had soon been halted when they moved against the French, and Hitler would not approve his request for an Italian occupation of the Rhone Valley, Toulon, and Marseille. The armistice left Italy with almost nothing to show for its first military effort in support of the Axis.

Diplomatic Reverses for the Axis Powers.—In the summer of 1940, Hitler let it be known publicly and privately that he was prepared to make peace with Britain if she would restore the colonies that Germany had lost in 1919 and renounce any influence in continental Europe. When the British showed no interest in his proposals even after they had been made in public on July 19, he intensified his planning for a direct assault on Britain, and by early September a German invasion force was held in readiness on the French coast. But German efforts to achieve air superiority in the Battle of Britain and the necessary naval strength fell short of success, and Hitler renounced an invasion in 1940.

Setbacks in the war against Britain required Germany to undertake new diplomatic maneuvers. On September 27, Germany, Italy, and Japan formalized the Axis coalition by signing the Tripartite Pact in Berlin. Under its provisions, Japan recognized the new order that Germany and Italy were creating in Europe; Germany and Italy recognized Japan's right to create a new order in the Pacific region; and all three nations pledged themselves to form a military alliance against any power that might enter the war against one of them (it was well understood that this provision was directed

against the United States). But the pact did not disguise the fact that Hitler's plans for vanquishing Britain had failed.

Hitler's inability to counter British defiance, obvious by October, had other major repercussions. The policies of Portugal and Spain, for example, were unavoidably affected. Both nations, previously on good terms with Berlin, refused to respond to attempts to bring them into the war on the Axis side. Pétain, too, thwarted Hitler by declining to engage France in military action against Britain. And in Florence on October 28, in a conference with Mussolini, the führer met fresh disappointment. The duke had wished to strike for territorial gains in the Balkans when he entered the war in June, but Hitler, who had his own plans for the peninsula, held him back. The Italian dictator greeted the führer in Florence with the proud announcement that Italian troops had crossed the Greek frontier at dawn. Although Hitler feared that this step would provoke British intervention in the Balkans, he could only contain his rage and return to Berlin.

Nazi-Soviet Friction.—There were further disturbing developments for Hitler in November 1940. In that month he reached a stalemate in his negotiations with the USSR, and in crucial conferences with Molotov was unable to buy him off. Hitler's cooperation with the Soviet Union had been rewarding. It had hastened Poland's fall in 1939. It had also brought economic advantages; by June 1940, 22 percent of all German imports were received from the Soviet Union and the Baltic states. But tension had arisen between Berlin and Moscow. Just when German troops were most deeply committed in the west and Hitler could not prevent Soviet expansion, the Kremlin used military pressure to incorporate the three Baltic states in the Soviet Union (June 15–Aug. 6, 1940). At the same time, the USSR moved against Rumania. On June 23, the day after the French surrendered at Compiègne, Molotov informed Germany that the Bessarabian question must be settled at once. The Nazi-Soviet Pact of August

On one of the 50 United States destroyers traded to Great Britain in 1940 in exchange for military bases, American sailors show British sailors how depth charges are laid.

1939 had promised the USSR a free hand in Bessarabia, but now Molotov laid claim to Bucovina, which had not been recognized as part of the Soviet sphere of influence. Berlin remonstrated with him, and on June 26 the Soviets agreed to limit their demands to Bessarabia and the northern portion of Bucovina. On June 28, the Soviet Army moved into the coveted areas, which were immediately incorporated in the USSR.

Hitler was now determined to prevent further Soviet expansion in central-eastern Europe. Ignoring the fact that the Nazi-Soviet Pact had placed Finland in the Soviet sphere of influence, Berlin on September 12 concluded an agreement with Helsinki that permitted its troops to cross Finnish territory to Norway. On November 20, Hungary joined the Tripartite Pact, and Rumania and Slovakia followed its example on November 22. While the original pact had been directed against the United States, the new additions obviously formed an anti-Soviet bloc.

There was more reason for Stalin to become alarmed than the Soviet dictator realized. On July 31, Hitler had ordered his generals to prepare for a possible invasion of the USSR in May 1941. Before committing himself to war with the Soviet Union, however, he seems to have determined to make a last attempt to reach an agreement that would keep the USSR out of the Balkans and direct its energies against the British Empire. On Nov. 12, 1940, Molotov arrived in Berlin for important negotiations. When Hitler and Ribbentrop proposed that the USSR move toward the Indian Ocean against the British positions in Iran and India, Molotov demanded instead that German troops be withdrawn from Finland, indicated that the USSR planned additional annexations there, requested that Germany's guarantee of Rumania be revoked, and insisted that the Soviet Union had

greater interest in Rumania, Hungary, Bulgaria, Turkey, and the Dardanelles than in expansion toward the Indian Ocean. The meetings ended inconclusively, and on December 5, Hitler approved plans for an attack on the USSR that were embodied in the directive of December 18 for Operation Barbarossa. The attack was to be ready by May 15, 1941.

In the next few months diplomatic and military preparations for the invasion of the USSR were pressed forward. In December 1940, in order to clear his southern flank, Hitler approved plans to move German forces through Bulgaria to aid Italy against the Greeks. Bulgaria came under effective German domination in February 1941, and signed the Tripartite Pact on March 1. Yugoslavia, which had already presented difficulties to German planners, now became even more troublesome. On March 22, Ribbentrop gave Belgrade until the next day to agree to enter a pact with Germany. After agonizing deliberation the Yugoslav government signed the Tripartite Pact in Vienna on March 25, but on March 26-27, Serb patriots revolted against the regency government of Prince Paul and proclaimed the adolescent King Peter II of age. That afternoon, Hitler ordered an early attack on Yugoslavia, and on April 6 German bombers struck at Belgrade. Within 11 days the German Army, aided in the north by many Croats, was in control of the country. King Peter and his ministers left Yugoslavia to create a government in exile. Meanwhile, Croatia was proclaimed an independent state and functioned thereafter as an Axis satellite. Germany and Hungary annexed large portions of Yugoslav territory in the north and east, while Italy acquired more than either of them, including the greater part of the coast. In addition, Bulgaria annexed a sizable area of Yugoslav Macedonia.

In Greece the sequel to the German invasion of Yugoslavia was soon completed, and Athens itself fell on April 27. Greece proper was subjected to joint German-Italian occupation and deprived of territory. Italy annexed the Ionian Islands and added Greek territory to its holdings in Albania, while Bulgaria was permitted to seize part of Greek Macedonia and Thrace, thereby restoring the frontier of 1913. The Greek government joined others in exile.

Thus, by the spring of 1941 almost all of Europe west of the USSR was under the direct or indirect control of Germany. But the German attack on the Soviet Union was launched a full month later than Hitler had planned. In delaying Germany, Yugoslavia and Greece had made an important contribution to the ultimate Allied victory.

German Attack on the Soviet Union.—Aside from Hitler's overt actions, which should have demonstrated to Stalin what was coming, Churchill and President Franklin D. Roosevelt warned the Kremlin of German preparations to attack the USSR. It appears, however, that the Soviet armies were taken by surprise when the German invasion began on June 22, 1941. Hitler did not act alone. On the day of the German attack, Italy and Rumania declared war on the USSR; Slovakia joined them on June 23; Finland followed their example on June 26, and Hungary on June 27. Japan, Hitler's partner in the Far East, remained neutral, and Bulgaria, though occupied by German military missions,

also was formally neutral.

Meanwhile, thousands of miles from the Soviet battlefields, decisions were made that transformed the conflict into a global war, assured the eventual defeat of the Axis powers, and laid the basis for a new balance of power after 1945.

United States Abandonment of Strict Neutrality.—In the first months of the war the United States was aroused against the Soviet Union as well as against Nazi Germany, but existing neutrality legislation and isolationist sentiment made it impossible for President Roosevelt to take effective action with regard to either nation. Material aid, even after the lifting of the strict embargo on arms shipments with the amendment of the Neutrality Act of 1937 on Nov. 3, 1939, was limited to what the British and French could purchase for cash and transport without using American ships. Pro-Allied sentiment was intensified by the Nazi victories in the spring of 1940 and by Italy's declaration of war against France and Great Britain in June. Thereafter some weapons and ammunition were made available to the British, British pilots were trained in Florida, and British warships were repaired in American shipyards. Then, on September 3, the White House announced more significant support for Britain: the trade (by executive agreement) of 50 overage destroyers in return for rent-free leases of 99 years on sites for American military bases in Newfoundland, Bermuda, the Bahamas, Jamaica, other Caribbean islands, and British Guiana. Congress adopted the Selective Service Act (signed September 16), authorizing the first peacetime military conscription in American history.

Reelected to a third term as president in November, Roosevelt proposed in December a new form of aid to the Allies, which was adopted by Congress as the Lend-Lease Act of March 11, 1941. With supporting appropriations, the act provided at the outset \$7 billion worth of war materials for nations whose defense the president deemed "vital to the defense of the United States." At the end of March, 69 Italian, German, and Danish ships in American ports and Philippine waters were seized, and approximately 875 seamen were jailed for "attempted sabotage." Other semibelligerent steps were taken by Washington during the first half of the year. Beginning in January, informal military and naval staff talks were conducted by American and British officers, who made tentative plans for joint efforts in the event that the United States should be drawn into war with Germany or Japan. On April 9, by agreement with Denmark's minister to Washington, the United States, fearful that Germany might take over Greenland, occupied the Danish island. From similar motives the United States assumed in July the defense of Iceland that Britain had provided since May 1940. Meanwhile, on May 27, 1941, stressing the dangers of nazism to the Western Hemisphere, Roosevelt proclaimed an unlimited national emergency. On June 14, all German and Italian assets in the United States (and those of other Axis-controlled European countries not previously affected) were frozen. June also saw the closing of all German and Italian consulates in the United States and of American consulates in Germany and Italy.

Hitler's attack that month on the USSR (for which few Americans had previously shown cordiality) brought quick promises of American as well as British aid to the beleaguered Soviet Union. Despite provisions of the Neutrality Act, United States ships were permitted to carry aid goods to Soviet ports. To coordinate joint defense measures and provide a basic declaration of common war aims, Roosevelt and Churchill met in August on shipboard off Argentina, Newfoundland. In the Atlantic Charter (q.v.), issued after the meeting, they subscribed to certain general principles for achieving peace. The two leaders stated that no territorial changes should be made contrary to the wishes of the inhabitants of the territories involved, and they recognized the right of people to choose their own forms of government. Greater freedom of trade and freedom of the seas were affirmed as war aims, as was international cooperation to improve conditions of labor and social security. Armaments were to be reduced, and a "permanent system of general security" was to be created. In addition, the aggressor nations were to be disarmed.

Since midsummer, American naval vessels had been employed to convoy merchant ships bound for Great Britain. Then, on September 11, Roosevelt announced that henceforth naval ships on convoy duty would not wait for hostile action but would take the initiative in attacking Axis war vessels. In carrying out this policy, an American destroyer, the *Reuben James*, was sunk by a German submarine west of Iceland on October 30. On November 13, Congress repealed the most troublesome provisions of the Neutrality Act of 1939, thereby sanctioning trade with Great Britain and permitting American merchant vessels to be armed. Hoping to avoid full-scale intervention by the United States, Hitler and Mussolini (like Roosevelt himself) had refused to be provoked into an open declaration of war. Having moved hesitantly toward belligerency in the Atlantic, the United States found that war came instead in the Pacific.

Japanese Steps Toward War.—The outbreak of war in Europe in 1939 at first left Japanese prospects in the Far East relatively unchanged. The situation became much more advantageous for Japan in the early summer of 1940, when Germany overran the Low Countries and France. Indochina, with its resources of rice and rubber, could not rely on support from Vichy France if Japan moved to extend its sway there; the Netherlands East Indies, with its oil, could no longer be effectively protected by the Dutch; and, since Great Britain was hard pressed by Germany, even British Malaya's rubber and the strategic base at Singapore lay exposed to attack as never before in the 20th century. The European war had created a power vacuum in Southeast Asia and the Southwest Pacific, presenting Japan with a unique opportunity for expansion. Only the USSR and the United States could stand in its way, and both powers seemed preoccupied with the war in Europe.

In Washington it was hoped that Japan might be contained by diplomatic and economic measures. Thus, on July 25 and July 31, 1940, the United States in effect placed an embargo on the export of scrap metal and petroleum without a special license and of all aviation gasoline to

Left to right: Kichisaburo Nomura, Cordell Hull, and Saburo Kurusu call at the White House on Nov. 17, 1941.

Wide World

Japan, while continuing to permit trade in other commodities. The creation on July 17 of a new cabinet headed by Prince Fumimaro Konoye made uncertain at best the prospects of containing Japan peacefully. The new foreign minister, Yosuke Matsuoka, was ambitious in his objectives and rash in his methods. Late in July, the cabinet reached an agreement on basic foreign policy objectives. The possibility of launching an attack in the south before the end of hostilities with China was discussed. If Japan should strike in the south, an attempt would be made to limit the war to Britain. Since this course might make war with the United States inevitable, however, Japan must prepare thoroughly for that possibility, while endeavoring to keep the United States neutral. The cabinet began at once to implement the new policy. An ultimatum of September 22 was followed by the movement of Japanese troops into northern Indochina. On September 26, immediately after the ultimatum became known, the United States proclaimed a total embargo on the sale of scrap iron and steel to Japan. The next day, Japan entered into the Tripartite Pact with Germany and Italy, having reached the decision to do so before proclamation of the embargo. It was the hope of the cabinet that this step would keep the United States from attempting to block Japanese expansion.

Shortly after occupying northern Indochina, Japan increased its efforts to force Generalissimo Chiang Kai-shek to capitulate. The United States reaction to this campaign, as well as to the occupation of northern Indochina and the conclusion of the Tripartite Pact, was to expand its aid to China. Meanwhile, Japanese pressure on the Netherlands East Indies grew, and by January 1941 there was talk in Tokyo of using force in that area. Because of concern that this pressure might lead to armed conflict with the United States, Japanese intelligence services were ordered to intensify their collection of data on American naval strength and placement. In January, Adm. Isoroku Yamamoto, commander in chief of the Japanese Combined Fleet, secretly suggested the possibility of a surprise attack on

the United States Pacific Fleet at Pearl Harbor. At the same time, United States, British, and Dutch leaders began trying to coordinate defense measures in preparation for a possible attack on the Indies.

The German invasion of the USSR in June gave the Japanese more certain assurance than the neutrality pact that Matsuoka had concluded in Moscow on April 13 that Japan could advance toward the south without concern for the possibility of Soviet action in Manchuria. For Matsuoka, however, the invasion had different implications. For years Japanese militarists had justified their imperialistic policies in Manchuria and China proper as defensive measures against Soviet communism and had looked forward to the day when Japan could attack the USSR. The German invasion presented a unique opportunity for an anti-Bolshevik crusade in Asia, and on June 22, Matsuoka recommended to Emperor Hirohito that Japan make war on the Soviet Union. But now that the moment had arrived for action, it was passed over, and in mid-July, Matsuoka was dropped from the cabinet. Meanwhile, on July 2, an Imperial Conference determined that Japan's first objective in the new circumstances would be to bring the war in China to a successful conclusion, while simultaneously advancing toward the south. Japan would "not decline a war with England and the United States" if this should become necessary to achieve her objectives.

The decisions of July 2 were soon implemented. Under an agreement forced on Vichy France on July 23, Japan occupied southern Indochina. In response, Japanese assets in the United States were frozen on July 25, and similar action was taken by Great Britain and the Netherlands. A new cabinet was formed in Japan on October 18. Gen. Hideki Tojo, minister of war in the Konoye cabinet, retained that position and also became prime minister and minister of home affairs. On November 5, after weeks of high-level discussions, an Imperial Conference decided on a final attempt to reach an agreement with the United States. But if a settlement favorable to Japan was not achieved by December 1, war would begin forthwith.

On November 20, the Japanese ambassador in Washington, Adm. Kichisaburo Nomura, and a special envoy, Saburo Kurusu, were instructed to present Japan's last proposal for a temporary settlement. Under its terms both countries would agree to begin no new armed expansion in Southeast Asia or the South Pacific; Japan would withdraw its troops from southern Indochina on the conclusion of the agreement and from northern Indochina when the war with China was ended; the United States would give Japan a free hand to bring the war against China to a successful conclusion; and it would lift the embargo on strategic exports to Japan, release Japanese assets in the United States, agree to supply petroleum as generously as in the period 1936-1940, and join with Japan to ensure access by both countries to the resources of the Netherlands East Indies. This proposal was an ultimatum. A government that had no concern for the global balance of power might have agreed to it; the American leaders could not. From decoded Japanese messages the United States government knew that rejection of the proposal would very likely be followed by a Japanese resort to war, probably against Southeast Asia. In rejecting the proposal

on November 26, the United States presented a counterproposition. It suggested that Japan evacuate both China and Indochina immediately and recognize Chiang Kai-shek's regime as the only government of China. A favorable trade treaty would be negotiated between Japan and the United States, and Japanese assets would be unfrozen. In addition, the two governments would enter into a multilateral nonaggression pact for the Far East.

On December 1, an Imperial Conference reached a formal decision for war with the United States. A last message to the United States government was drafted in Tokyo, to be delivered in Washington on the eve of the attack on Pearl Harbor. It was not an explicit declaration of war, but a rejection of Secretary of State Cordell Hull's proposals of November 26; it declared that negotiations were being broken off. Because of technical delays in the Japanese embassy in Washington, Hull was given the message by Japan's representative at 2:20 P.M. on Dec. 7, 1941, more than an hour after the first bombs fell at Pearl Harbor.

The specific attack on Pearl Harbor on December 7 came as a surprise to the commanders there and to officials in Washington. It accomplished the formal entry of the United States into World War II. On December 8, Congress declared that a state of war had been thrust on the United States by Japan. In accordance with the Tripartite Pact and in response to Japanese requests, Germany and Italy on December 11 declared war on the United States; Congress reciprocated the same day. The conflict begun by Hitler's invasion of Poland in 1939 was now in fact a global war.

FROM AXIS MASTERY TO ALLIED RECOVERY: 1941-1943

From 1941 through 1943 the Allies fought stubbornly, forged weapons, and designed a strategy to wrest the initiative from the Axis. Meanwhile, Axis exploitation of the captive nations served as a constant reminder to the Allied peoples of what was at stake in the global war.

Greater East Asia Coprosperity Sphere.—The Japanese leaders knew the value of slogans. Wartime proconsuls pictured Japan as the liberator of Asians from Western colonial rule and appealed to the people whose lands they overran to help them in a common effort. Japan's mission, Tokyo proclaimed, was to build a new order in Asia for the Asians. The Japanese named their far-flung dominion the Greater East Asia Coprosperity Sphere (see Map 35). The reality of Japanese rule was considerably less appealing than the propaganda. The pattern of Japanese dominance had long been established in Korea, where a systematic policy of Japanization was pursued. In Manchuria, which had been taken from China in 1931 and renamed Manchukuo, a similar pattern evolved, although there the Japanese took greater pains to erect a façade of indigenous government. Exploitation was just as obviously the Japanese goal in occupied China. In 1940, Japan chose a well-known Nationalist defector, Wang Ching-wei, as its puppet. Established at Nanking on March 30, 1940, his regime on Jan. 9, 1943, declared war on the United States and Great Britain.

Patterns of Japanese control for several other areas had to be devised after the expansion of 1940-1941. British Malaya was kept under direct

military administration and scheduled for eventual incorporation in the Japanese Empire. The Netherlands East Indies also remained under Japanese military administration, but Indochina escaped such rule until March 10, 1945. Thailand, an independent state before 1941, became Japan's ally under duress. Occupied by Japanese troops, it declared war on the United States and Great Britain on Jan. 25, 1942. Thanks to native collaborators, Burma and the Philippines also became allies of Japan. Increasingly, as the fortunes of war turned against them, the Japanese gave lip service to a goal of independence for the captive areas. Nevertheless, the grip of Japan was always maintained, and everywhere the native economies suffered. Meanwhile, Nazi Germany was ruling Europe with even greater severity than Japan employed in Asia.

Hitler's Europe.—The Nazi wartime empire (see Map 1) was an improvised makeshift, but it gave Adolf Hitler power that no modern European had ever held. Areas that had been parts of pre-1918 Germany and others that had large German-speaking populations were incorporated directly in the Third Reich. The incorporated territories were Austria; the Sudetenland; northwestern Poland, including Danzig, the Polish Corridor, and Posen (Poznań); and Eupen, Malmédy, and Moresnet, taken from Belgium in 1940. Other provinces—Alsace, Lorraine, Luxembourg, northwestern Yugoslavia, and northwestern Poland (Province of Białystok)—were not considered ready for full incorporation but were earmarked for eventual merger in the Reich. Approximately half of central-eastern Europe was scheduled to be a permanent Continental colonial realm, including the Baltic states, the Government-General of Poland (about one third of prewar Poland), White Russia, the Ukraine, and the Protectorate of Bohemia and Moravia.

In 1940-1941, German forces overran other territories that Hitler planned neither to incorporate in Germany nor to subordinate permanently as colonies. During the war these states were placed under a military occupation that was said to be temporary; they included Norway, Denmark, the Netherlands, Serbia, Greece, and France. Within these states native governments were allowed to function under varying degrees of supervision by German occupation authorities. Bulgaria, Hungary, Rumania, Croatia, Slovakia, and Finland were satellite allies of Germany. They remained politically subservient, economically exploited, and occupied by German troops. Even Mussolini's regime was subordinated to Berlin, especially after the duke's downfall and reinstallation by Hitler in northern Italy in 1943. In that year, Germany occupied the areas in Albania and Yugoslavia that the Fascist state had previously controlled and added the South Tirol (Alto Adige), which Italy had possessed since 1919, to Greater Germany.

In all the areas except the allied and neutral countries, Germany maintained its control by ruthless terrorism. Even less defensible was the deliberate genocide (q.v.) that German forces practiced in order to fulfill the racist dogmas of the Nazis. By the end of the war, Hitler bore ultimate responsibility for killing possibly as many as 5,700,000 Jews. While furthering the extermination of "non-Aryans," Nazi racial policy fostered the conversion of part Germans to full German citizenship.

By exploiting non-German peoples, Germany

marshaled the human, natural, and industrial resources of the Continent between 1940 and 1944. Its economic realm produced 45 million tons of steel for the German war machine in the year of greatest output, or more than either Britain or the USSR produced. Together, however, the British and the Soviets produced more; and the United States alone, even early in the war, produced as much steel as all of Hitler's Europe. The Nazi empire was to be broken down slowly but inexorably after the war spread to the Soviet Union and the Western Hemisphere.

Search for Solidarity in the Western Hemisphere.—Even before the attack on Pearl Harbor, the United States had begun to mobilize the resources of the Americas in the struggle against the Axis powers. The success that was attained owed much to the Good Neighbor policy of the prewar decade. It also owed something to Axis agents and to the zeal of Latin American Nazis and fascists, whose activities convinced many of their countrymen that the Axis threat was not abstract and remote.

The first collective action by nations of the Western Hemisphere to meet the dangers of World War II had been taken during the first month of the conflict. In the Declaration of Panama, adopted on Oct. 3, 1939, foreign ministers of the 21 American nations south of Canada declared a "safety belt" around the hemisphere, extending from 300 to 1,000 miles from the eastern and western coastlines; the European belligerents were warned to desist from naval and military operations in this area. The foreign ministers of the American republics met again in Havana on July 21–30, 1940, to assess the implications of the Nazi conquests in western Europe. By the Act of Havana of July 30 they proclaimed that, pending final disposition, European colonies in Latin America might be made collective trusteeships of the American republics to prevent unfriendly powers from establishing control over them; any of the republics could act in an emergency while awaiting concerted measures. They also declared that any violation of "the territory, the sovereignty, or the political independence" of an American state by a non-American state should be considered an act of aggression against all of the republics. Canada, a member of the British Commonwealth of Nations, was not represented at the Havana Conference, but on August 17 the United States joined with it in agreeing to create a Permanent Joint Board on Defense, which would plan the security of the northern half of the hemisphere.

When the Japanese attacked Pearl Harbor in 1941, Costa Rica, Cuba, the Dominican Republic, El Salvador, Guatemala, Haiti, Honduras, Nicaragua, and Panama immediately declared war on the Axis powers. Meeting in Rio de Janeiro on Jan. 15–28, 1942, the foreign ministers of the American republics resolved that all of them should sever diplomatic relations with the Axis. All did so at the time except Chile, which acted in January 1943, and Argentina, which delayed until January 1944. Mexico and Brazil sent troops overseas to help in the war effort. Argentina's refusal to cooperate with the other republics was the most troublesome facet of wartime diplomacy in the Western Hemisphere and a major problem that confronted the Inter-American

Conference on Problems of War and Peace, meeting at Chapultepec Castle, Mexico City, on Feb. 21–March 8, 1945. With Argentina deliberately excluded, the other republics declared that all were joint guardians of each against any aggression; Argentina was notified that she could be admitted to the future United Nations only if she adhered to the Act of Chapultepec and entered the war. The Argentine provisional government on March 27, 1945, declared war against Germany.

Consolidation of the Allied Coalition.—Concerting the policies of the American republics was an important task; maintaining the coalition and directing the energies of the great-power Allies was even more imperative. Berlin and Tokyo, not their own choices, had made them allies, and they would not regain full freedom of decision until their common foes were defeated.

During the week before the German invasion of the USSR in June 1941, Churchill advised Roosevelt of his intention to aid the Soviets when the German attack fell, and Roosevelt promised his support. Shipping difficulties caused Stalin to be dissatisfied with the amount of aid that he received, and after the war Soviet historians would contend that all Western supplies did not exceed 4 percent of the wartime production of the USSR. But the aid given in 1941–1942 came at a time when the Soviet Union needed it most. By mid-1942, Britain and the United States had sent 4,400 tanks and 3,100 planes to the Soviet Union. Quite possibly the Soviet Army could not have held out without them, as Stalin himself seemed to confess at Teheran (Nov. 28–Dec. 1, 1943).

Coordination within the Big Three coalition in 1941–1942 was, as it always would be, imperfect. In July 1941, Churchill failed to persuade Stalin to promise the restoration of the prewar Polish-Soviet frontier. On July 30, however, Moscow established diplomatic relations with the Polish government in exile, which it previously had scorned. Other differences and signs of harmony appeared. In September, Stalin renewed his aggrieved demands for a second front in the west in 1941, and this problem caused Churchill great concern. So, too, did the revelation of Soviet war aims made to Anthony Eden when the British foreign secretary visited Moscow in December. The Soviet proposals served as a reminder that Stalin's approval of the Atlantic Charter had been qualified. The Soviet leaders wanted Britain to agree to their retention of all the territory they had acquired while collaborating with Hitler and somewhat more for good measure. Unwilling to accept all the Soviet proposals and fearful of splitting the coalition if they rejected them, London and Washington adopted a policy of postponement and in public statements gave voice to general principles rather than to specifics.

On Jan. 1, 1942, the USSR joined the United States, Great Britain, China, France, and 21 other countries in signing the Declaration by United Nations in Washington. This pact pledged each participant "to employ its full resources, military or economic," against the Axis powers and to make no "separate armistice or peace with the enemies." Member nations, including the USSR, "subscribed to" the Atlantic Charter's "common program of purposes and principles," although these were not repeated in the declaration. The USSR remained faithful to its new

ality pact of April 1941 with Japan, but this raised no serious problems within the new coalition. To consolidate the Allied coalition an Anglo-Soviet alliance, pledging mutual support against aggression for a period of 20 years, was signed on May 26, 1942. Behind this pact lay Western hopes for friendly relations after the common victory over the Axis.

For the moment, however, Hitler allowed Stalin no security, and the Soviet dictator relentlessly reiterated his demand for an early second front in western Europe. In May-June 1942, Molotov traveled to London and Washington to press this issue. President Roosevelt finally approved a statement, made public on June 11, which implied that a second front would be created in Europe before the end of the year. This insufficiently qualified statement could not be fulfilled, for Churchill and his generals favored giving precedence to an invasion of North Africa over a cross-Channel attack. The North African invasion was launched on November 8.

The reconciliation of the French factions in North Africa was a major task for Roosevelt and Churchill when they met at Casablanca in newly liberated French Morocco on Jan. 14-24, 1943. There the rival leaders of Free France, Generals Henri Giraud and Charles de Gaulle, were now urged to work together. On June 3, their diverse supporters created a French Committee of National Liberation with headquarters in Algiers. This body established its control over French colonies in northern and central Africa and directed an underground resistance movement in France. Gradually de Gaulle asserted his mastery over the committee.

At Casablanca, Roosevelt and Churchill also considered their disagreements on strategy and their relations with Stalin. Their military decisions at this conference were certain to cause greater suspicion and concern in Moscow: an invasion of Sicily would be carried out at an early date, but the invasion of France, so much desired by Stalin, would be delayed, possibly until 1944. Somehow Stalin had to be assured of Western

loyalty without an early second front and without specific political promises. This consideration probably was the dominant motive for the act for which the Casablanca Conference is remembered, the proclamation of a policy of unconditional surrender. After deliberation with Churchill the formula was announced by the president on January 24. Peace could come, Roosevelt said, only by eliminating German and Japanese war power, and this meant "unconditional surrender by Germany, Italy, and Japan." While the public statement may have prolonged the war, this is by no means certain. It avoided bickering within the Allied nations that might have sapped their military energies, and it may well have forestalled serious Soviet efforts for a separate peace with Nazi Germany in 1943, when months passed without a second front in northwestern Europe.

In the spring of 1943 the British urged new delays in the creation of a second front in France, and in the Trident Conference, held in Washington on May 12-25, the Americans reluctantly acquiesced in their desire to invade the Italian Peninsula soon after Sicily was in hand. During the discussion, Churchill hinted at the desirability of limited operations in the Balkans. The American military leaders opposed this suggestion: they would do so again when Churchill and Eden later pressed it with greater vigor. Meanwhile, it was agreed to postpone the cross-Channel invasion until May 1, 1944. A storm of Soviet protests arose when Stalin was advised in June of the Trident decisions. As negotiations developed in August and September leading to the surrender of Italy, other disagreements between London and Washington developed, and Stalin (generally omitted from the decision making) repeatedly aired his suspicions of Western policies. Then Hull and Eden traveled to Moscow for major discussions (Oct. 19-30, 1943) of political aims in the war. They assured the Russians of plans to invade France in the spring of 1944, and tensions within the coalition were eased. When Roosevelt, Churchill, and Stalin themselves met

The Allied Big Three meet at Tehran (Nov. 28-Dec. 1, 1943): left to right, Joseph Stalin, Franklin D. Roosevelt, and Winston Churchill.

Wide World

at Teheran at the end of November for the first Big Three talks, the Soviet dictator was given more definitive assurances on November 30 that the second front was to be established in France in May 1944. Roosevelt and Churchill also led Stalin to believe that his major political objectives would be achieved at the end of the war. Friendly relations seemed to be firmly established among the three war leaders. In Italy, meanwhile, the events of 1943 had brought the Allies closer to victory.

First Crack in the Axis: Surrender in Italy.—Mussolini's control over Italy had been shaken by the Allied victory in North Africa in the spring of 1943. On July 24–25, leading Fascists, generals, and King Victor Emmanuel conspired to remove the duce from power, and a new government was created with Marshal Pietro Badoglio as premier. On September 3, the day Allied troops landed on the Italian mainland, Badoglio's regime signed a secret armistice with the Western Allies. Because German forces remained in the peninsula, hard fighting would continue until April 1945 between German and Allied armies in central Italy. Meanwhile, after the autumn of 1943, armed Italian underground units harried the Germans in northern Italy; in 1944 and 1945 they received increasing assistance from the Allies.

The Italian armistice and political problems in southern Italy created friction among the Allies. On Oct. 13, 1943, the Western Allies permitted the Badoglio regime to declare war on Germany, thus achieving a status of *cobelligerency* with the Allies. The USSR was informed of the various developments but was scarcely consulted. Then disagreements between Washington and London allowed Stalin to exert somewhat greater influence in Italy. On March 13, 1944, the Anglo-American leaders were surprised by the announcement of an agreement between the Victor Emmanuel-Badoglio regime and the USSR. While the British and the Americans were debating the future of the monarchical government, the USSR had given it diplomatic recognition and thus a new lease on life. The Western Allies arranged for Victor Emmanuel to retire in favor of his son, Crown Prince Humbert, in June. Thenceforth they would recognize the monarchical regime until the Italian people decided in favor of a republic in 1946. By their exclusive occupation of Italy, Britain and the United States guaranteed that this state would be linked closely to them in the future.

False Approaches to Peace.—The events in Italy in 1943–1944 and German reversals in the Soviet Union stimulated consideration of possible ways to end the war short of total military decision. Japan had not declared war on the USSR and was free to seek a separate peace between that nation and Germany. From March 1942 through September 1944, Tokyo occasionally suggested to Berlin and Moscow the possibility of Japanese mediation, but without success. Separate Soviet overtures were made toward Germany in December 1942, June 1943, and September 1943, but Hitler did not respond. In September 1943, he told Joseph Goebbels that what he wished to win in the East, "Stalin could not renounce." Both in 1943 and in 1944 reports of peace feelers circulated in the capitals of the Western Allies and caused anxiety. Possibly, sensing this, Stalin kept the potentiality of a separate peace open only to enhance his bargaining power.

Other possibilities of shortening the war by political action were explored in these years. Nazi Germany encouraged revolution against the Kremlin, while Moscow used anti-Nazi Germans in the Soviet Union to urge German soldiers and civilians to desert or to rise against Hitler. Both efforts were made with reservations and failed to accomplish the desired results.

Meanwhile, leaders of the anti-Nazi resistance movement in Germany urged British and American representatives to give them encouragement for revolution. Apparently they received very little; certainly they requested much. In general, they wished Germany to retain Austria, the Sudetenland, and part of pre-1939 Poland. They also wanted the Western powers, after making a separate peace with a Germany purged of Hitler, to allow Germany to continue the war against the USSR. The resistance depended on the support of Wehrmacht generals, and the Western Allies were determined to crush German militarism as well as nazism. These considerations were probably more significant than the unconditional surrender policy in causing the unenthusiastic response of the Western powers to resistance overtures. Even without Western encouragement the resistance leaders wounded Hitler in an attempt to kill him on July 20, 1944, and tried to revolt against his regime. Distrusted by the West before July 20 and brutally crushed by Hitler after the unsuccessful revolt, the German resistance movement was not destined to succeed in its efforts to shorten the war.

ALLIED WAR AIMS AND POLICIES FOR PEACE 1943–1945

The cross-Channel invasion of June 6, 1944, was followed by a rapid Anglo-American movement through France in late July and August. The Allied armies were often aided by local uprisings of the French resistance. These events altered the relations between de Gaulle and Roosevelt, who had remained unwilling to recognize the Committee of National Liberation as a French government even when the invasion was launched. That had not prevented de Gaulle from proclaiming it the provisional government of the French Republic on June 2. Roosevelt's anger at this *fait accompli* was calmed when de Gaulle visited Washington in July. The United States then gave *de facto* recognition to the provisional government. French units participated after August 1 in the liberation of France, and de Gaulle staged a triumphant parade in Paris on August 26, the day after the city was jointly liberated by French and American forces. *De jure* recognition of de Gaulle's regime was granted formally by Britain, the USSR, and the United States on October 23.—At this time and in the months to come, de Gaulle made plain his determination that France should be treated in all respects as an equal of the great Allies.

The military successes in France, like others since 1943, gave promise that the East-West Allies would be able to write their own terms at the end of the war if they could agree on them. Problems mounted as the cement holding the Allied coalition together—German and Japanese military might—began to crumble.

Basic Problems.—Knowledge of Soviet demands in December 1941 had caused Churchill and Roosevelt to avoid agreements on peace terms. At that time the Soviet leaders wanted the British to agree immediately to the reinfor-

poration in the USSR of all the territory that Stalin had taken while in partnership with Hitler: Estonia, Latvia, Lithuania, and parts of Finland, Poland, and Bessarabia (they also wished additional Finnish territory and air bases in Rumania). Other Soviet aims seemed to be approximately in harmony with those of the West: Austria, Czechoslovakia, Albania, Greece, and Yugoslavia were to be restored as independent states with as much territory as they had held before being seized by the Axis powers; Poland would gain territory at the expense of Germany; and Germany would be dismembered and curbed in other ways. No suggestion was made that any of these states should be Soviet satellites after the war, and Stalin promised his support for any arrangement Britain might wish to make for the future of France, Belgium, the Netherlands, Denmark, and Norway.

The war aims announced to Eden in December 1941 did not make it appear that Stalin's ambition in the world at large was insatiable. In addition to dissolving the Communist International (Comintern) in May 1943 and stressing patriotism over Communist ideology within the USSR, the Soviet leaders joined those of Britain, China, and the United States in declaring on Oct. 30, 1943, that they would not use their military forces in the territories of other states for selfish political purposes after the war. For their part, Roosevelt and Churchill wished to satisfy the Soviet desire for security, while placing limits on Soviet expansion.

The conflict between Soviet pressures for early agreement on peace terms and Western attempts to limit and delay them can be followed in all the great conferences in which postwar policies were discussed: the foreign ministers' conference, held in Moscow (Oct. 19–30, 1943); the Teheran Conference (Nov. 28–Dec. 1, 1943); the Yalta Conference (Feb. 4–11, 1945); and the Potsdam Conference (July 17–Aug. 2, 1945). Roosevelt died on April 12, 1945, and President Harry S. Truman represented the United States at Potsdam; Clement R. Attlee, who became the new British prime minister during the conference, replaced Churchill.

Creation of the United Nations.—Stalin's participation in wartime planning of the future United Nations organization offered hope for friendly East-West relations after the war. Soviet willingness to cooperate was announced in the four-power declaration of Oct. 30, 1943. At Teheran, Roosevelt and Stalin found themselves in general if tentative accord on the broad principles of operation of the new organization. Fleshing out the bare bones of these principles proved to be more difficult at Dumbarton Oaks in Washington (Aug. 21–Oct. 7, 1944). Here it was decided to call the new organization the United Nations. It was to have a large legislative body, the General Assembly, and a small executive committee, the Security Council. In the Council, Great Britain, the USSR, China, and the United States would be permanently represented; they would be aided by rotating members chosen by the Assembly. The right of veto in the Council by the great powers on basic matters affecting their security and sovereignty (a major American provision) won approval, but there was disagreement over the limits to be placed on the use of this right by these powers. This dispute could not be reconciled at once, and a stalemate also was reached on the Soviet de-

mand for 16 seats in the General Assembly.

The search for a suitable compromise was one of the major problems before the Big Three when they met at Yalta in February 1945. At first, Stalin vigorously and stubbornly insisted on the full veto power in all issues before the Security Council. On February 7, however, Soviet approval of the American voting formula was given: no member of the Council, when a party to a dispute, was to vote on resolutions for its pacific settlement; in decisions on procedural matters the great-power members also would lack the veto power. Moreover, the Soviet Union agreed to reduce its demand for seats in the General Assembly from 16 to 3. Churchill, who was sensitive about the then-projected 6-seat representation of the Commonwealth of Nations, favored the revised Soviet proposal, and Roosevelt agreed to it. The decision was reached that a conference to found the United Nations should meet in the United States on April 25, and that France as well as China should have permanent seats with the Big Three in the Security Council.

When the San Francisco Conference convened on April 25, 1945, to organize the United Nations, President Truman learned that Stalin had retreated from the Yalta agreement to limit use of the veto. The question at San Francisco was again whether permanent members of the Security Council could prevent discussion of disputes. Stalin finally agreed to adopt the American position. The USSR also sought to restrict freedom of discussion in the General Assembly, but in the end it agreed that the Assembly could discuss any matters "within the scope of the present Charter." Over Soviet protests, Argentina was admitted to the United Nations. Soviet attempts to secure the seating of Poland failed, for Poland was now governed by a Soviet puppet regime, and the United States refused at San Francisco to allow it membership. The United Nations Charter was adopted unanimously at San Francisco on June 26, but the dispute over the seating of Poland was typical of other problems on which no agreement had been found.

Poland and Central-Eastern Europe.—Churchill later described the Polish problem as the "first of the great causes which led to the breakdown of the Grand Alliance." Two major questions disturbed Big Three harmony: What frontiers should postwar Poland have, especially with the Soviet Union? What should be the character of its government?

The question of the Polish-Soviet frontier (see Map 2) was rooted in historical antagonism, the ethnic mixture of the disputed area, the structure of the Polish state between the two world wars, and the growth of Soviet power and ambition. Weak in 1921, Soviet Russia had been forced to agree to a frontier that left 5 million White Russians and Ukrainians inside Poland. In 1939, however, Stalin had gained more than the ethnic Curzon Line by cooperating with Hitler. After 1941 he insisted that the Ribbentrop-Molotov line of 1939–1941 should become the post-war frontier. When the Polish government in exile refused to agree and called for an investigation of the Katyn massacre (see section 3, *Early Campaigns*), Stalin, in April 1943, broke off diplomatic relations with it and groomed pro-Soviet émigrés in the USSR to serve as a future government of Poland. Thus, insofar as the Polish issue was concerned, Churchill was ready even in 1943 to abandon the Western policy of

postponement; seeking to forestall the creation of a Soviet satellite regime, both Churchill and Roosevelt in 1944 urged the London Poles to accept the Curzon Line as a frontier. Their refusal helps to explain why the Soviet Army failed to aid pro-Western Polish patriots who rose against the Germans in Warsaw on August 1. On Jan. 5, 1945, despite Roosevelt's protest, the USSR recognized the pro-Soviet Poles as the government of Poland.

By this time the Soviet Army controlled almost all of the country, and the Yalta Conference was virtually confronted by a *fait accompli*. Stalin argued that his Warsaw regime was as representative as the de Gaulle government in France and the government of Italy, which were backed by the West, but he finally conceded that a few of the London Poles could be associated with the Warsaw regime and agreed that free elections should be held in Poland "as soon as possible." The Big Three also decided that the Polish-Soviet frontier should follow the Curzon Line with minor digressions in favor of Poland. Poland was to receive German territory in the west, although agreement could not be reached on an exact Polish-German frontier. In a Declaration on Liberated Europe, the Big Three promised to support interim governments that were pledged to early free elections in areas taken from Nazi Germany. Thanks to continued Western pressure, in the months after Yalta a few pro-Western Poles were admitted to the pro-Soviet Warsaw regime to form a slightly broader government that the West recognized, but the USSR adhered to its demand that the line of the Oder and Western Neisse (Lusatian Neisse) rivers become the Polish-German frontier. After much discussion the Western leaders at Potsdam agreed that, pending a peace treaty, German territory east of the Oder-Neisse line (except for East Prussia) should be "under the administration of the Polish state."

Meanwhile, on Dec. 12, 1943, the USSR had signed a treaty of alliance with the government in exile of Czechoslovakia amid promises by Stalin that he would not interfere in Czech internal affairs. On Sept. 19, 1944, an Allied-Finnish armistice was signed, restoring the status quo of March 12, 1940, with slight revisions, and leaving Finland free of Soviet occupation. Then, on October 9, Churchill and Stalin privately decided on a division of at least temporary influence in the Balkans as the area was liberated from Germany. The USSR would be predominant in Rumania and Bulgaria; influence would be shared equally in Yugoslavia, where the British had backed Marshal Tito's Partisans since 1943, and in Hungary; and Britain would be predominant in Greece. It was already understood that the Soviet Union was to regain Bessarabia and northern Bucovina. The presence of the Soviet Army after August 1944 in central-eastern Europe ultimately enabled the USSR to control more than the Stalin-Churchill agreement had promised, but Western control in Greece was safeguarded by the British occupation of that country after October.

Dilemma over Germany.—While the East-West dispute over the reorganization of the Polish government continued, the Third Reich crumbled under the weight of the Allied advance. Hitler committed suicide on April 30, 1945. Germany surrendered to the Western Allies on May 7 and to the Russians in Berlin on May 9. The

capitulation found the Allies lacking in agreement on a postwar German policy. During the period 1941–1944 the Big Three had seemed to be basically in accord, but by early 1945 fundamental differences had begun to appear. For Stalin the crippling of Germany seemed essential to the attainment of either security for the USSR and or the spread of communism. For Roosevelt and Churchill the German problem was a dilemma that they could not fully solve: How could Germany's domination of Europe be broken without leaving the Continent under the sway of the USSR?

On some policies agreement in principle was easily achieved: Germany must be denazified, disarmed, and demilitarized, and she must surrender war criminals for punishment (all of which required military occupation by the victors); she must pay reparations and have her war industries eliminated or controlled; and she must be reduced in size and either decentralized or dismembered. Formal agreement on these principles was reached unanimously at Yalta; tacit approval had been given much earlier. But behind the agreement on general principles there were massive problems of interpretation. Essential problems remained without clear-cut solutions even after the Big Three parted at Potsdam in August 1945.

Plans for the occupation of Germany were outlined by the British in 1943, negotiated in 1944, and formally approved at Yalta in 1945. As shown in Map 15, the final agreement provided that Britain was to occupy northwestern Germany, the United States the south, and France the southwest; the eastern third of pre-1938 Germany was to be occupied by the USSR. Joint occupation policy was to be defined by a four-power Allied Control Council in Berlin which would thus be occupied jointly by the Allies. Since it was thought that common occupation policies were to be imposed on Germany, no concern was expressed over the fact that jointly occupied Berlin would be surrounded by the Soviet zone of occupation, though Roosevelt in 1943 had favored United States occupation of northwestern Germany up to and including Berlin.

Full agreement on reparations and deindustrialization could never be achieved. In August–September 1944, the United States secretary of the treasury, Henry Morgenthau, Jr., had proposed a program for sweeping deindustrialization and the transfer of plants and equipment to Allied nations as reparations. Roosevelt and Churchill tentatively approved this plan but then retreated from it. At Yalta, Stalin made its principles his own. He proposed that Germany furnish \$20 billion worth of reparations, of which the USSR would receive half; this would be collected by removing 80 percent of Germany's heavy industry in the name of eliminating her war capacity. Since they could not agree, the Big Three decided to create a reparations commission, which would adopt the Soviet demand for \$10 billion in kind as a "basis for discussion." The commission also failed to reach an agreement, as did the Big Three at Potsdam. There they decided that the USSR might receive up to 25 percent of the industry removed from the Western zones of occupation, where most German industry was located, but they could not decide on how much should be removed altogether. The problem was to remain troublesome

throughout the period of occupation, during which the USSR ravaged its own zone and obtained considerable equipment from the Western zones.

Since 1943 the Allies had generally agreed that Germany must cede territory. The restoration of Austrian independence and of pre-1938 Czechoslovakia was undisputed, and no one argued against giving German territory to Poland, but even at Yalta the Big Three could not decide on the amount. In the spring of 1945 the Russians took matters into their own hands and at Potsdam insisted on recognition of the Oder-Neisse line as the German-Polish frontier. The Western leaders reluctantly agreed to recognize Polish "administration" of territory as far west as the "Oder-Neisse Line," pending the formulation of a peace treaty for Germany. Truman and Attlee also agreed "in principle" to the absorption of Königsberg (renamed Kaliningrad) and surrounding territory in East Prussia by the USSR, the definitive frontier to be determined by a future peace conference.

As early as December 1941, Stalin had called for the permanent partition of Germany into separate states. At Teheran both Roosevelt and Churchill indicated their general approval of this suggestion, but they disagreed about the extent of the dismemberment and reserved any final decision. At Yalta, Stalin again pressed vigorously for dismemberment, but again Roosevelt and Churchill thought it too early to make a definitive decision; the Big Three agreed only to "take such steps, including . . . the dismemberment of Germany as they deem requisite for future peace and security." In March and April 1945, Roosevelt continued to favor postponement of a decision in this matter, and on May 9, Stalin proclaimed that the Soviet Union did not intend "either to dismember or to destroy Germany." Asked later that month why he had changed his mind, Stalin told Harry Hopkins that "his recommendation had been turned down at Yalta." Yet, ironically, *de facto* partition was to be accomplished after 1945 by Stalin's refusal to merge his zone of occupation with the Western zones to form a free and united German state. The postwar disagreements over Germany had been clearly foreshadowed at Yalta and Potsdam, but they were not allowed to disrupt the wartime coalition; the defeat of Japan was yet to be accomplished.

Soviet Aid Against Japan and Far Eastern Policy.—The likelihood of Soviet participation in the war against Japan and the general character of Soviet aims were foreshadowed by earlier Far Eastern history. In 1875, Russia had surrendered to Japan her claim to the Kuril Islands, and her defeat in the Russo-Japanese War of 1904–1905 had left Japan in control of Port Arthur (Lüshun), Dairen (Talien), and the railroads of Manchuria (held by Russia before 1905), as well as of Korea (see Map 54). Russia retained control over the northern half of Sakhalin, and in the 1920's established its influence over Outer Mongolia. War against Japan after 1941, if successful, would enable Stalin to win back what the czars had lost and even more unless the West could build a strong China.

The creation of a strong China was to be a frustrating task. In the period 1941–1943 only token American military support could be given to Nationalist China. Chiang Kai-shek, caught up in a civil war with Chinese Communist armies

while fighting Japan, could be dissuaded only with difficulty in 1943 from directing his war effort against the Communists. The latter were as eager to expand the territory under their control as Chiang was to extend his. To chart greater Allied aid to China and to concert political policies, Roosevelt arranged to have Chiang meet with him and Churchill at Cairo on Nov. 22–26, 1943, before the Western leaders went to Teheran. The supply of war materials to Chiang by air across the Himalaya from India was to be increased, and Chiang was treated as an equal of the great Allies. By the Cairo Declaration of Dec. 1, 1943, Roosevelt, Churchill, and Chiang announced their determination to strip Japan of her conquests.

But international political understanding did not solve China's internal weaknesses. In the summer and fall of 1944, Vice President Henry A. Wallace, Ambassador Patrick J. Hurley, and Gen. Joseph W. Stilwell urged Chiang to seek cooperation with the Communists so that the war against Japan could be waged most effectively. Their success was negligible, and Stilwell was recalled in October at Chiang's request. Meanwhile, although American aid was increased, the Nationalist forces yielded more territory to the Japanese. The military failures of China strengthened the desire in Washington for Soviet aid in the war against Japan.

As early as 1941, Roosevelt and Chiang had suggested that the USSR enter the Far Eastern war, but the idea had not been pressed. On Dec. 1, 1943, Stalin informed Roosevelt and Churchill at Teheran that the USSR would declare war on Japan after Germany had been defeated. At the same time he expressed an interest in gaining southern Sakhalin, the Kuril Islands, and use of the Manchurian railroads and Dairen. In December 1944, Stalin again outlined these goals to United States Ambassador W. Averell Harriman and added Port Arthur to the list. Roosevelt and Churchill could not prevent Stalin from obtaining what he requested, and an agreement on these gains might forestall more sweeping annexations. Thus a secret Yalta agreement of Feb. 11, 1945, provided that the USSR should obtain southern Sakhalin and the Kuril Islands; Soviet interests should be preeminent in an internationalized Dairen; Port Arthur should be leased to the USSR; the Manchurian railways were to be operated by a Soviet-Chinese company that would make Soviet interests in the railways preeminent but respect full Chinese sovereignty over Manchuria; and the status quo of Soviet influence in Outer Mongolia was to be preserved. It appeared that Stalin was repudiating the Chinese Communists, for the Yalta agreement stipulated that he was prepared to conclude a "pact of friendship and alliance" with the Nationalist Chinese government. Finally, Stalin agreed to make war against Japan "in two or three months" after Germany surrendered.

At the time of the Yalta agreements, American military leaders desired the entry of the USSR in the war against Japan. The atomic bomb had not yet been tested. Although by July 24, 1945, it was ready for use, the Combined Chiefs of Staff then recommended to Truman and Churchill that they encourage Soviet entry. Meanwhile, fear of Soviet entry and the hope of playing the Soviet Union against the West had prompted Japanese peace efforts through Moscow. In Tokyo, Japanese leaders were willing to

concede the Soviet territorial demands of Yalta and more. At Potsdam, Stalin reported the overtures to Truman and Churchill, who separately agreed to give the Japanese a last warning to surrender.

In the Potsdam Declaration of July 26, the Americans, British, and Chinese threatened heavier attacks if Japan held out. On July 28, Japan announced that it would ignore this warning. Hoping for a change in the Japanese attitude, Truman delayed the use of the atomic bomb on Hiroshima until August 6. On August 8, the USSR declared war (effective August 9). Influenced by this development and by the dropping of a second atomic bomb on Nagasaki on August 9, civilian leaders in Tokyo sought a settlement that would leave the emperor on his throne. The Allied powers quickly agreed, and on August 14, Japan accepted the Allied terms. Meanwhile, Soviet forces had overrun most of the areas promised them at Yalta. On Sept. 2, 1945 (September 1, United States time), the formal Japanese surrender was made to General of the Army Douglas MacArthur on board the battleship *Missouri* in Tokyo Bay. World War II was over.

15. Postwar World

The last wartime Big Three conference, held at Potsdam on July 17–Aug. 2, 1945, determined how peace treaties would be drawn up. Instead of an immediate conference like that following World War I, there were to be preliminary meetings of a Council of Foreign Ministers, representing Great Britain, France, the United States, the Soviet Union, and China. Debate could proceed in relative leisure; hasty and ill-considered compromises could be avoided; and when a peace conference finally assembled, it could devote itself to really important issues. Such, at any rate, were the hopes of the Potsdam conferees.

The initial foreign ministers' meetings were, however, disappointing. That in London (Sept. 11–Oct. 2, 1945) dissolved into a wrangle over procedure. Those in Moscow (Dec. 16–26, 1945) and Paris (April 25–May 16, 1946) broke up because of substantive disagreements, particularly concerning the amounts and kinds of reparations to be paid the USSR by Italy, the disposition of the region around Trieste, and the question of whether one of the former Italian colonies in Africa should be assigned to the Soviet Union as a United Nations trusteeship.

SATELLITE TREATIES

When the Council reconvened in Paris (June 15–July 12, 1946), however, the members were able to reach substantial accord on treaties not only for Italy but also for Bulgaria, Rumania, Hungary, and Finland. Although differences of opinion remained, they agreed to submit these treaties to a general peace conference. Delegates from the 5 nations and the 16 others that had been allied with them assembled in Paris on July 29–Oct. 15, 1946. The Council of Foreign Min-

isters, meeting in New York on Nov. 4–Dec. 12, 1946, compromised remaining points of disagreement. Final texts of the five treaties were signed in Paris on Feb. 10, 1947. As a result of their ratification by the requisite number of states, all came into force on Sept. 15, 1947.

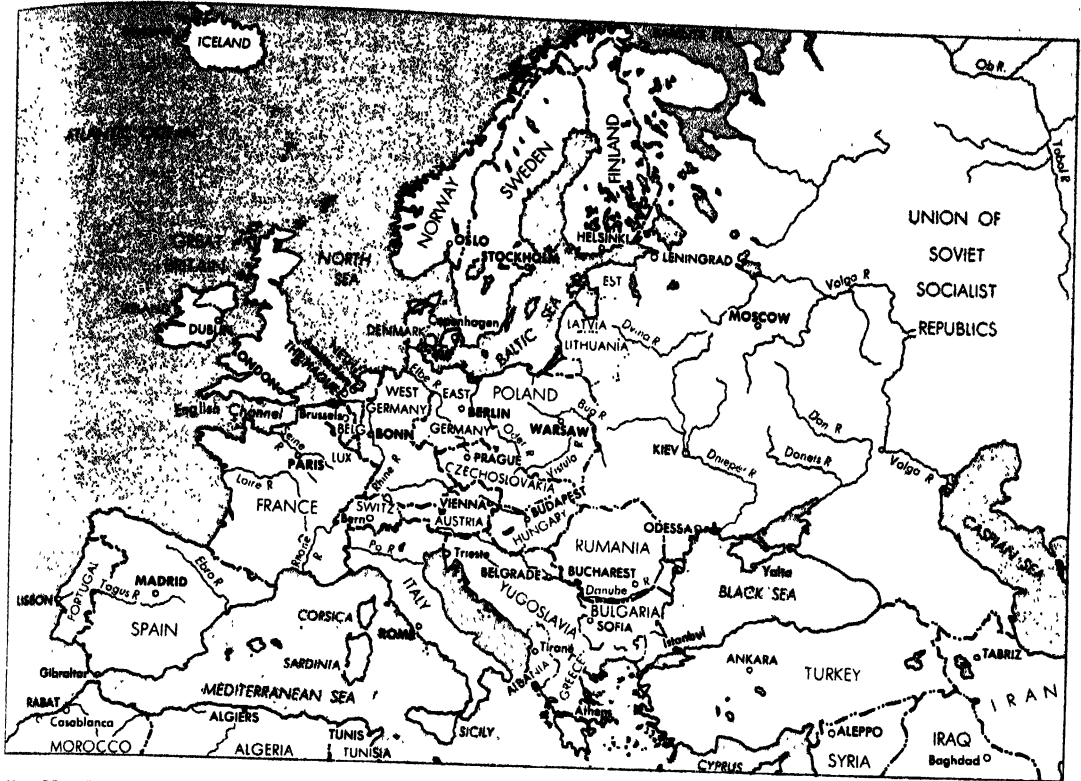

Italian Peace Treaty.—The preamble to the Italian treaty contained a war guilt clause somewhat like that which had been included in post-World War I peace treaties. It asserted that Italy had undertaken "a war of aggression and thereby provoked a state of war with all the Allied and Associated Powers and with other United Nations," and that it bore a "share of responsibility for the war." But it also asserted that the principal Allies expected, by the treaty, to settle questions still outstanding, and that they would support Italy's application to become a member of the United Nations.

The treaty's *territorial clauses* provided for minor rectifications of the Franco-Italian frontier, with France to receive the Little St. Bernard Pass, the Mont Cenis (Moncenisio) plateau, and small portions of the Mont Thabor (Monte Tabor) and Chaberton regions, and the upper valleys of the Tinée, Vésubie, and Roya (Roia) rivers. Yugoslavia was to get a small border area south of the boundary between the Italian provinces of Udine (Friuli) and Gorizia, the Province of Zara (Zadar), and the adjacent Dalmatian islands. Greece was to obtain the islands of the Dodecanese, while the Trieste area was to become a free territory guaranteed by the United Nations.

The *political clauses* of the treaty stipulated that Italy should "take all measures necessary to secure to all persons under Italian jurisdiction without distinction as to race, sex, language or religion, the enjoyment of human rights and of the fundamental freedoms, including freedom of expression, of press and publication, of religious worship, of political opinion and of public meeting." No penalties were to be visited on Italian nationals because of wartime partisanship for the Allies. The Italian government undertook to prevent the resurgence of Fascist organizations or any others, "whether political, military or semi-military, whose purpose it is to deprive the people of their democratic rights."

Italy renounced sovereignty over her former colonies, Libya, Eritrea, and Italian Somaliland, agreeing that their final disposal should be determined by the USSR, Britain, the United States, and France or, failing an agreement among those powers, by the United Nations General Assembly. She relinquished all special rights in China and surrendered to the Chinese government the Italian concession at Tientsin and Italian rights in the international settlements of Shanghai and Amoy. Recognizing the sovereignty and independence of Albania and Albanian possession of the island of Saseno (Sazan), she abandoned all special rights in that country and surrendered to the Albanian government all Italian state property there. Similarly recognizing the sovereignty and independence of Ethiopia, she gave up all special claims and rights there and undertook to return all works of art, religious objects, archives, and objects of historical value taken after Oct. 3, 1935. Italy also promised to apprehend and surrender for trial all persons accused of war crimes.

The *military clauses* required the destruction of fortifications on the Franco-Italian and Yugoslav-Italian frontiers and the demilitarization of

Map 55. POSTWAR EUROPE. Territorial changes shown go as far as the partition of the Free Territory of Trieste between Italy and Yugoslavia in 1954.

zones 20 kilometers deep on the Italian side. Pantelleria, the Pelagic Islands, Pianosa, and northern Sardinia were to be completely demilitarized, southern Sardinia and Sicily, partially so. Italy was not to possess, construct, or even experiment with atomic weapons, self-propelled or guided missiles, long-range guns, noncontact mines and torpedoes, manned torpedoes, aircraft carriers, or submarines, and she was forbidden to acquire or manufacture war material beyond relatively limited amounts specified in an annex to the treaty. The warships that she could retain were similarly specified in an annex. Naval personnel were not to exceed 25,000. The army and carabinieri together were not to exceed 250,000. The air force was not to have more than 25,000 men and 350 planes.

Reparations clauses provided that Italy should pay the equivalent of \$360,000,000—\$125,000,000 to Yugoslavia, \$105,000,000 to Greece, \$100,000,000 to the USSR, \$25,000,000 to Ethiopia, and \$5,000,000 to Albania. These payments were not to be in money but in goods; surplus war material, capital goods, or, after a period of grace of two years, goods from current industrial production. Quantities and types were to be determined by bilateral negotiation, but it was stipulated that goods should be selected and deliveries scheduled "in such a way as to avoid interference with the economic reconstruction of Italy and the imposition of additional liabilities on other Allied and Associated Powers." While waiving all claims against these powers, Italy also promised to restore to them at her own expense all property that had been taken from their nationals.

In the upshot the Allies were unable to agree on the Italian colonies, and the issue went to the United Nations General Assembly. As a result of votes there, Libya, which had been under British and French administration, became an independent kingdom on Dec. 24, 1951; Eritrea, at first under British administration, federated with Ethiopia on Sept. 15, 1952 (in 1962, Eritrea decided to unite with Ethiopia); and Somaliland, also at first under British administration, became an Italian trusteeship on April 1, 1950, and joined with the Somaliland Protectorate (British Somaliland) to form an independent republic, Somalia, on July 1, 1960. Trieste never became a self-governing territory, for the city and its environs and the Gorizia region to the northwest (Zone A) remained under Anglo-American occupation, while the southern portion (Zone B) continued to be garrisoned by Yugoslav troops, and these arrangements ended only when, on Oct. 5, 1954, Italy and Yugoslavia agreed to a partition. Zone A returned to Italy; Zone B became part of Yugoslavia. Moreover, in December 1951–January 1952, Italy won from 14 of the 21 signers of the treaty consent in principle to a modification of the military clauses, and thereafter the Italian government did not heed them.

Bulgarian Peace Treaty.—The Bulgarian treaty had a preamble similar to that of the Italian treaty. Its territorial clause provided simply that Bulgaria's frontiers should be those of Jan. 1, 1941. This meant that the southern Dobruja, which had been transferred to Bulgaria in 1940, would remain Bulgarian. The political clauses referring to civil liberties, the suppression of fascist activities, and the surrender of war crim-

inals were identical with those in the Italian treaty, as were the military clauses relating to new weapons. The Bulgarian Army was not to consist of more than 55,000 men, the antiaircraft artillery force of more than 1,800, the navy of more than 3,500, or the air force of more than 5,200. The navy was to be limited to 7,250 tons; the air force, to 90 planes. Installations for offensive warfare were not to be maintained along the Greek frontier. As for reparations, the Bulgarians were to turn over manufactures, raw materials, and agricultural products to the value of \$70,000,000—\$45,000,000 to Greece and \$25,000,000 to Yugoslavia. In addition, the Soviet Union was to be accorded title to most German assets in the country. Aside from a special clause providing for free navigation of the Danube River, the rest of the treaty was also similar to the Italian.

Rumanian Peace Treaty.—The Rumanian treaty was much like the Bulgarian. Rumania's frontiers were to be those of Jan. 1, 1941, thus confirming the cession that had been made to the USSR on June 28, 1940, of Bessarabia and northern Bucovina, and to Bulgaria on Sept. 7, 1940, of southern Dobruja. The only exception was the Rumanian-Hungarian frontier, which was to be restored to the status of Jan. 1, 1938. Northern Transylvania was thus to be returned to Rumania. Among the political clauses was one which had been omitted from the Bulgarian treaty because of that country's relatively good record in regard to racial minorities. This pledged the Rumanian government not to enact laws that should "either in their content or in their application, discriminate or entail any discrimination between persons of Rumanian nationality on the ground of their race, sex, language or religion." Under the military clauses the army was to be limited to 120,000 men, the antiaircraft artillery force to 5,000, the navy to 5,000, and the air force to 8,000, with 15,000 tons set as the limit on the fleet and 150 planes as the limit on the air force. Reparations consisting of \$300,000,000 worth of commodities were to be made over to the USSR within eight years from Sept. 12, 1944, and the Rumanian government joined in promising free navigation on the Danube. Like the Italian and Bulgarian treaties, that for Rumania pledged the withdrawal of Allied forces within 90 days. It made an exception, however, for the Soviet Union, entitling it to keep on Rumanian territory "such armed forces as it may need for the maintenance of the lines of communication of the Soviet Army with the Soviet zone of occupation in Austria."

Hungarian Peace Treaty.—The Hungarian treaty was like the Rumanian, including the political clause forbidding discrimination. It restored the frontiers with Czechoslovakia, Austria, Yugoslavia, and Hungary to the status of Jan. 1, 1938, except for the cession to Czechoslovakia of an area across the Danube from Bratislava. It fixed limits of 65,000 men on the Hungarian Army and 5,000 men and 90 aircraft on the Hungarian Air Force. Reparations goods to the value of \$200,000,000 were to be paid to the USSR. Another \$100,000,000 worth was to be divided by Czechoslovakia and Yugoslavia in proportions to be agreed on by those states. In Hungary as in Rumania, Soviet troops were to retain lines of communication to Austria.

Finnish Peace Treaty.—Although the United States was not a party to the Finnish treaty, never having declared war on Finland, the document did not differ materially from the others. It

included a political clause forbidding discriminatory legislation. Finland's frontiers were to be those of Jan. 1, 1941, thus confirming the accessions of territory made by the Soviet Union as a result of the Winter War of 1939–1940. In addition, Finland was to cede to the USSR the Province of Petsamo (now Pechenga); and, in return for Soviet renunciation of the right to lease the Hangö (Hanko) Peninsula, to confirm a 50-year Russian lease on a naval base on the Porkkala Peninsula, with appropriate rights of access. The Finnish Army was to be limited to 34,400 men, the navy to 4,500 men and 10,000 tons, and the air force to 3,000 men and 60 planes. In addition, \$300,000,000 worth of commodities were to be transferred to the USSR as reparations.

LATER DEVELOPMENTS

Although subsequent foreign ministers' conferences devoted much time to discussion of treaties for Austria, Germany, and Japan, little progress resulted. Even at the time of the signing of the satellite treaties, the United States and the USSR had been drawing apart. Clashes between them in 1947 and 1948 created increasing tension, and by the end of the latter year their relationship was accurately characterized as one of cold war. In 1950 came armed conflict in Korea between Soviet-backed Communist forces on one side and United Nations forces led by the United States on the other.

Japanese Peace Treaty.—Meanwhile, the United States government had grown increasingly impatient about maintaining an expensive and, in its judgment, no longer necessary occupation of Japan. Consequently, in 1950 President Harry S. Truman circularized the various governments that had been wartime allies, proposing the drafting of a Japanese Peace Treaty. A special presidential mission then visited many capitals, including Tokyo, and formulated terms that the majority would accept. A conference was called to meet in San Francisco on Sept. 4–8, 1951, and 51 nations, including the USSR, agreed to send representatives. Although the Soviet, Czechoslovak, and Polish delegates refused to sign the treaty, the other 48 delegates did so. An adequate number of governments then ratified the document, and it came into force on April 28, 1952.

Making no reference to war guilt, the preamble merely asserted that the Allied powers and Japan were "resolved that henceforth their relations shall be those of nations which, as sovereign equals, cooperate in friendly association to promote their common welfare and to maintain international peace and security." It stated that Japan would apply for membership in the United Nations and conform to the principles of the United Nations Charter. By the territorial clauses of the treaty, Japan recognized the independence of Korea and renounced all claims to Taiwan (Formosa), the Penghu Islands (Pescadores), the Kuril Islands, the southern part of Sakhalin, and the mandates which she had held from the League of Nations. She stated that she would concur in any United States proposal to make the Ryukyu Islands, the Bonin Islands, the Volcano Islands, Parece Vela, and Marcus Island into United Nations trusteeships under the exclusive control of the United States.

A special set of clauses labeled "security" provided that Japan should "refrain . . . from the threat or use of force against the territorial integrity or political independence of any State"

but also recognized that as a sovereign nation she possessed "the inherent right of individual or collective self-defense" and might therefore enter into collective security agreements with other governments. There were no clauses limiting the Japanese armed forces.

While fixing no sums for reparations payments, the treaty stipulated that any of the former Allies might seize and retain certain assets of Japanese nationals, that similar assets held in neutral countries should be turned over to the International Committee of the Red Cross to be used for former prisoners of war and their families, and that the Japanese government would negotiate with each of her former enemies about making compensation for wartime damage by lending the services of Japanese technicians and workmen.

Austrian State Treaty.—In March–April 1955, the Soviet Union unexpectedly indicated that it was prepared to negotiate a treaty for Austria. A conference promptly convened in Vienna; a treaty was signed on May 15; and it came into force on July 27, 1955. Although its preamble treated Austria as a liberated nation rather than as a former enemy, many of the specific provisions were similar to or identical with those in the satellite treaties of 1947. The Austrian government was obliged to prevent the revival of Nazi or fascist organizations and not to enact any discriminatory legislation. The use of Croat and Slovene in schools and official documents was guaranteed for regions where members of these nationalities formed substantial minorities. Although numbers were not fixed for the Austrian armed forces, atomic weapons, guided missiles, and the like were forbidden, and specified limits were placed on the amounts of war material that Austria could possess. While reparations as such were not to be exacted, the treaty gave the USSR a 30-year concession on approximately 60 percent of the country's oil-bearing land and control over most of its refineries. In return for the surrender of certain former German assets, the Soviet Union was also to receive \$150,000,000 in currency. Special clauses forbade any political or economic union of Austria and Germany or even agitation in such a cause; stipulated that the nation should have a democratic government, the secret ballot, and free, equal, and universal suffrage; and directed that a ban be maintained against the return of the house of Habsburg.

After the Austrian State Treaty, progress toward a peace settlement halted again. The Soviet Union and the United States disagreed completely about Germany, and the provisional regimes in the eastern and western zones of that country hardened into permanent governments. While World War II appeared to have brought a final end to the conflict that had begun in 1914, the era after it had some of the characteristics of another long armistice—an armed truce between West and East.

16. Chronology

A chronological outline of the major events preceding World War II, the chief military and political occurrences in the various areas during the war, and peace treaties and other postwar developments are presented under the following headings: (1) prelude to war, (2) European and Mediterranean operations, (3) Pacific and eastern Asian operations, and (4) political and diplomatic developments of the war and postwar periods.

PRELUDE TO WAR

1931

Sept. 18—Japanese begin conquest of Manchuria.

1932

March 1—Manchuria becomes Japanese puppet state of Manchukuo.

1933

Jan. 30—Adolf Hitler becomes chancellor of Germany.

March 27—Japan leaves League of Nations.

Oct. 14—Germany leaves League of Nations.

1934

Jan. 26—Germany and Poland sign 10-year nonaggression pact.

June 30—Hitler carries out blood purge of Nazi Party.

July 25—Unsuccessful pro-Nazi revolt takes place in Austria; Chancellor Engelbert Dollfuss is assassinated.

1935

March 16—Hitler reintroduces compulsory military service.

May 2—France and the USSR sign five-year mutual assistance treaty.

June 18—Anglo-German naval agreement is signed.

Oct. 3—Benito Mussolini invades Ethiopia.

1936

Jan. 15—Japan withdraws from London Naval Conference.

March 7—Hitler remilitarizes Rhineland.

May 5—Italians capture Addis Ababa, ending major operations in Ethiopia.

July 17–18—Spanish Civil War begins.

Oct. 25—Germany and Italy form Rome-Berlin Axis.

Nov. 25—Germany and Japan sign Anti-Comintern Pact.

1937

July 7—Marco Polo Bridge incident near Peiping sets off Sino-Japanese War.

Dec. 12—Japanese planes sink United States gunboat *Panay* in Yangtze River.

Dec. 13—Japanese sack Nanking.

1938

March 13—Hitler annexes Austria.

Sept. 29–30—Munich Conference approves German acquisition of the Sudetenland.

1939

March 15—Hitler occupies rest of Czechoslovakia.

March 28—Insurgent forces complete conquest of Spain.

April 7—Mussolini invades Albania.

Aug. 23—Germany and the USSR sign nonaggression pact.

EUROPEAN AND MEDITERRANEAN OPERATIONS

1939

Sept. 1—Germany invades Poland.

Sept. 17—Soviet forces invade Poland.

Sept. 27—Warsaw capitulates.

Oct. 6—Last organized Polish resistance is broken at Kock.

Nov. 30—Soviet forces invade Finland.

1940

March 12—Finland capitulates, signing Treaty of Moscow.

April 9—Germans begin invasion of Norway and seize Denmark.

April 14—Anglo-French forces reach Norway.

May 2—Anglo-French forces are driven from central Norway.

May 10—Germans invade the Netherlands, Belgium, and Luxembourg.

May 14—Dutch Army surrenders.

May 20—Germans break through to English Channel at Abbeville.

May 28—Belgium surrenders unconditionally.

June 4—British complete evacuation of Dunkerque.

June 6—Allies leave Narvik.

June 9—Norwegian Army agrees to armistice.

June 14—Germans enter Paris.

June 22—German-French armistice is signed (fighting ends June 25 after signature of Italo-French armistice June 24).

July 3—British attack French Fleet at Oran and Mers-el-Kebir.

July 10—Battle of Britain begins.

Aug. 5—Italians invade British Somaliland (conquest is completed Aug. 19).

Sept. 13—Italians invade Egypt.

Sept. 23—British and Free French attempt unsuccessfully to take Dakar (attack ends Sept. 25).

Oct. 28—Mussolini invades Greece.

Oct. 31—Germans begin breaking off Battle of Britain.

Dec. 9—Gen. Sir Archibald Wavell launches British counteroffensive in Egypt.

1941

Feb. 7—Trapped Italian army surrenders to British at Bedafora, Libya.

Feb. 12—Gen. Erwin Rommel arrives in Tripoli to take over North African campaign for Axis.

March 1—Italians finally check Greek counteroffensive.

March 5—British forces reach Greek mainland.

March 16—British land at Berbera, British Somaliland.

March 24—Axis forces launch offensive in North Africa (Tobruk is invested by April 11).

April 6—Axis forces invade Yugoslavia and Greece; British occupy Addis Ababa.

April 17—Yugoslav Army capitulates; British begin evacuating Greek mainland.

April 30—Organized resistance ends on Greek mainland.

May 2—British attack insurgents in Iraq (campaign ends May 31 with occupation of Baghdad).

May 20—Germans begin airborne attack on Crete.

May 31—Germans complete conquest of Crete.

June 8—British attack Vichy French forces in Syria, defeating them in six days.

June 22—Hitler invades the USSR.

Aug. 21—Hitler turns German main effort southward toward Kiev.

Sept. 8—Leningrad's land connections with rest of the USSR are severed.

Sept. 19—Kiev is captured.

Nov. 18—British begin second invasion of Libya.

Nov. 20—Germans capture Rostov.

Nov. 27—Conquest of Italian East Africa is completed with surrender of Gondar.

Nov. 28—Germans are forced to evacuate Rostov.

Dec. 5—German offensive stalls 25 miles from Moscow.

Dec. 6—Russians launch counteroffensive.

Dec. 7—Rommel begins withdrawal to El Agheila.

Dec. 10—British advance in Libya relieves Tobruk.

Dec. 24—British enter Benghazi.

1942

Jan. 2—British capture bypassed fortress of Bardia, Libya.

Jan. 11—Rommel withdraws westward toward El Agheila.

Jan. 17—British reduce bypassed German garrison of Halfaya.

Jan. 20—Russians recapture Mozhaisk, 65 miles west-southwest of Moscow.

Jan. 21—Rommel launches major counteroffensive.

Jan. 26—First United States troops arrive in Northern Ireland.

Jan. 28—British Eighth Army withdraws to El Gazala-Bir Hacheim Line.

Feb. 1—Soviet counteroffensive begins to bog down in German hedgehog defense system.

Feb. 12—German warships *Scharnhorst*, *Gneisenau*, and *Prinz Eugen* escape from Brest and run up English Channel to German ports.

March 27—British carry out successful raid against St.-Nazaire, France.

May 8—Germans begin minor operations to prepare for summer offensive in the USSR.

May 12—Russians launch large-scale spoiling offensive against Kharkov.

May 17—Germans counterattack in Kharkov sector.

May 27—Rommel launches major offensive against El Gazala-Bir Hacheim line.

May 28—Germans complete defeat of Soviet Kharkov offensive.

May 30—Royal Air Force begins major air offensive against Germany with heavy raid on Cologne.

June 10—Rommel forces evacuation of Bir Hacheim.

June 14—British withdraw toward Egypt.

June 20—Rommel breaks into Tobruk, completing its capture June 21.

June 24—Rommel reaches Sidi Barrani, Egypt.

June 28—Germans launch main summer offensive in the USSR.

June 30—British are forced back on prepared positions at El Alamein.

July 1—Germans complete capture of Sevastopol.

July 2—British Eighth Army begins limited counterattacks against Axis forces in Egypt.

July 4—American crews participate in Royal Air Force raid on airfields in the Netherlands, in the first

United States air operation in Europe.

July 6—Germans capture Voronezh, near Don River.

July 9—German offensive in the USSR divides, one army group advancing through Rostov into the Caucasus oilfields and the other toward Stalingrad.

 June 19—Japanese Fleet is badly defeated by United States carrier aviation in Battle of the Philippine Sea ("Marianas Turkey Shoot"; battle ends June 20).
 June 22—Japanese begin retreat from Kohima-Imphal area.
 July 9—Saipan is secured.
 July 21—Americans land on Guam.
 July 24—Americans land on Tinian, Mariana Islands.
 July 28—Organized Japanese resistance ends on Biak.
 July 30—Americans land on Vogelkop Peninsula, New Guinea.
 Aug. 1—Tinian is secured.
 Aug. 3—Myitkyina, Burma, is captured.
 Aug. 10—Organized Japanese resistance is destroyed on Guam.
 Aug. 20—Biak is secured.
 Aug. 29—Japanese continue successful offensive against American Honan air bases.
 Sept. 15—Americans land on Morotai Island and Palau Islands.
 Sept. 17—Morotai is secured.
 Oct. 10—United States Third Fleet carrier task force raids Okinawa.
 Oct. 13—United States Third Fleet begins raids on Taiwan.
 Oct. 15—Allies begin offensive to clear northern Burma.
 Oct. 17—United States Ranger units occupy small islands at entrance to Leyte Gulf.
 Oct. 18—General Stilwell is relieved.
 Oct. 20—United States Sixth Army invades Leyte.
 Oct. 21—Palau Islands are secured.
 Oct. 23—Battle for Leyte Gulf begins between United States and Japanese fleets (ends Oct. 26 with Japanese defeat).
 Nov. 24—B-29's make first raid on Tokyo from bases in Mariana Islands.
 Dec. 10—Japanese forces in southern China link up with Japanese forces in French Indochina.
 Dec. 12—British launch offensive in Arakan sector of Burma.
 Dec. 15—Americans invade Mindoro, Philippines.
- 1945**
 Jan. 1—Major offensive operations are completed on Leyte (mopping up continues until May 8).
 Jan. 2—United States convoys begin moving toward Luzon, Philippines.
 Jan. 3—British Arakan offensive recaptures Akyab.
 Jan. 9—United States Sixth Army begins landing at Lingayen Gulf, Luzon.
 Jan. 20—Converging attacks from China and Burma reopen Burma Road.
 Feb. 3—United States 1st Cavalry Division enters Manila.
 Feb. 16—Americans launch airborne-amphibious assault on Corregidor Island, Manila Bay (completed March 2); heavy preparatory naval-air bombardment of Iwo Jima. Volcano Islands, begins.
 Feb. 19—United States Marines land on Iwo Jima.
 Feb. 25—United States 21st Bomber Command makes first mass incendiary-bomb raid on Tokyo.
 March 3—Last Japanese position in Manila is wiped out.
 March 10—Americans land on Mindanao, Philippines.
 March 18—Iwo Jima is declared secure.
 March 18–19—United States carrier aircraft attack Japanese air and naval bases in preparation for coming invasion of Okinawa.
 March 21—British complete recapture of Mandalay, Burma.
 March 26—Americans land on Kerama-retto near Okinawa (islands are completely occupied March 28).
 April 1—United States Tenth Army lands on Okinawa.
 April 7—Japanese naval sortie toward Okinawa is routed (Battle of the East China Sea).
 April 11—Japanese begin furious air offensive, using Kamikaze aircraft, against United States shipping off Okinawa.
 May 3—British reoccupy Rangoon.
 May 11—Chinese forces halt Japanese drive on Chihkiang (begun April 1944).
 May 20—Japanese in China begin moving troops northward to reinforce their army in Manchuria.
 June 21—Organized Japanese resistance on Okinawa ends.
 June 30—Luzon is declared secure (mopping up continues until end of war).
 July 1—Australians and Dutch begin operations in Balikpapan area of Borneo.
 July 10—United States Navy and Army aircraft begin a major offensive against Japan in preparation for planned invasion.
 July 16—United States tests successful atomic bomb at Alamogordo, N.Mex.
 July 17—British Pacific Fleet joins United States Third Fleet in attacks on Japan.
 Aug. 6—Atomic bomb is dropped on Hiroshima.
 Aug. 8—The USSR declares war on Japan (effective Aug. 9).
 Aug. 9—Atomic bomb is dropped on Nagasaki; Russians invade Manchuria.
 Aug. 12—Soviet troops enter northern Korea.
 Aug. 14—Japan surrenders.

POLITICAL AND DIPLOMATIC DEVELOPMENTS OF THE WAR AND POSTWAR PERIODS

1939

- Sept. 3—Great Britain and France declare war on Germany.
 Sept. 28—Germany and the USSR revise nonaggression pact.

1940

- March 12—Finland capitulates, signing Treaty of Moscow.
 May 10—Winston Churchill becomes prime minister of Great Britain.
 June 10—Italy declares war on France and Great Britain (effective June 11).
 June 15—The USSR begins seizure of Lithuania, Latvia and Estonia (ends Aug. 6).
 June 22—German-French armistice is signed (fighting ends June 25 after signature of Italo-French armistice June 24).
 June 28—USSR seizes Bessarabia and northern Bucovina.
 July 25—United States begins embargo on shipment of strategic materials to Japan.
 Sept. 3—United States trades 50 destroyers for naval base sites in British possessions.
 Sept. 16—President Roosevelt signs first American peacetime Selective Service Act.
 Sept. 22—Japanese begin occupation of northern French Indochina.
 Sept. 26—United States imposes total embargo on scrap shipments to Japan.
 Sept. 27—Japan joins Axis (Tripartite Pact).
 Nov. 20—Hungary joins Axis.
 Nov. 22—Rumania joins Axis.

1941

- March 1—Bulgaria joins Axis.
 March 11—Congress passes Lend-Lease Act.
 March 25—Yugoslavia joins Axis.
 March 26–27—Anti-Axis coup d'état takes place in Yugoslavia.
 April 13—Japan and the USSR sign neutrality pact.
 May 27—Roosevelt proclaims unlimited national emergency.
 June 14—German and Italian assets in the United States are frozen.
 June 22—Germany, Italy, and Rumania declare war on the USSR.
 June 26—Finland declares war on the USSR.
 June 27—Hungary declares war on the USSR.
 July 23—Japan occupies southern Indochina.
 July 25—Japanese assets in the United States are frozen.
 Aug. 14—Roosevelt and Churchill issue Atlantic Charter.

Sept. 17—British and Soviet troops occupy Teheran, Iran.
 Dec. 8—Japan declares war on the United States and Great Britain; the United States and Great Britain declare war on Japan.
 Dec. 9—China declares war on Japan, Germany, and Italy.
 Dec. 11—Germany and Italy declare war on the United States, which then declares war on them.
 Dec. 24—British-American Arcadia conferences open in Washington (end Jan. 14, 1942).

1942

Jan. 1—Declaration by United Nations is signed by 26 countries.

April 8—Bolero Conference begins in London (ends April 14).

Oct. 22—To clear way for Operation Torch (Allied invasion of French North Africa), Maj. Gen. Mark W. Clark lands from submarine for secret meeting with pro-Allied French officers.

Dec. 24—Admiral Darlan is assassinated.

1943

Jan. 14—British-United States conference opens at Casablanca (ends Jan. 24).

May 12—Trident Conference opens in Washington (ends May 25).

July 25—King Victor Emmanuel III of Italy proclaims fall of Mussolini, replacing him with Marshal Pietro Badoglio.

Aug. 14—Quadrant Conference opens in Quebec, Canada (ends Aug. 24).

Sept. 3—Italian government signs armistice (effective Sept. 8).

Oct. 13—Italy declares war on Germany.

Nov. 22—Sextant Conference opens at Cairo, Egypt (recesses Nov. 26).

Nov. 28—Eureka Conference opens at Teheran, Iran (closes Dec. 1).

Dec. 1—Cairo Declaration is issued.

Dec. 3—Sextant Conference reopens at Cairo (closes Dec. 7).

1944

July 20—Attempt to assassinate Hitler fails.

Aug. 21—Dumbarton Oaks Conference opens (ends Oct. 7).

Aug. 23—Rumania surrenders unconditionally.

Aug. 25—Rumania declares war on Germany.

Aug. 26—Bulgaria opens negotiations for surrender with Allies.

Sept. 5—The USSR declares war on Bulgaria.

Sept. 8—Bulgaria declares war on Germany.

Sept. 9—The USSR grants Bulgaria an armistice.

Sept. 12—Rumania signs armistice; Octagon Conference opens in Quebec (ends Sept. 16).

Sept. 19—Allied-Finnish armistice is signed.

Oct. 23—Great Britain, the USSR, and the United States grant *de jure* recognition to French provisional government headed by Gen. Charles de Gaulle.

1945

Jan. 30—Preliminary Anglo-American phase (Cricket) of Argonaut Conference begins at Malta (ends Feb. 2).

Feb. 4—Second phase (Magnet) of Argonaut Conference opens at Yalta (ends Feb. 11).

March 3—Finland declares war on Germany.

March 10—Japanese place French Indochina under direct military administration.

April 5—The USSR notifies Japan that it intends to denounce their 1941 neutrality pact.

April 12—President Roosevelt dies.

April 23—Heinrich Himmler's offer to surrender German forces to Western Allies is rejected.

April 25—San Francisco Conference opens (adopts United Nations Charter June 26).

April 28—Mussolini is captured and killed by Italian partisans.

April 30—Hitler commits suicide.

May 7—German High Command surrenders all forces unconditionally at Reims.

July 17—Terminal Conference begins at Potsdam, Germany (ends Aug. 2).

July 26—Terminal Conference issues Potsdam Declaration, presenting surrender ultimatum to Japan.

July 28—Japanese announce that they will reject surrender ultimatum (rejected July 30).

Aug. 8—The USSR declares war on Japan (effective Aug. 9).

Aug. 10—Japan offers to surrender.

Aug. 14—Japan surrenders.

Sept. 2—Japanese representatives sign instrument of surrender aboard the battleship *Missouri* in Tokyo Bay.

Sept. 11—Big Four foreign ministers' meeting opens in London (ends Oct. 2).

Dec. 16—Foreign ministers' meeting opens in Moscow (ends Dec. 28).

1946

April 25—Foreign ministers' meeting opens in Paris (ends May 1)

June 15—Foreign ministers' meeting reconvenes in Paris, reaching substantial agreement on treaties for Italy, Bulgaria, Rumania, Hungary, and Finland (ends July 12).

July 16—Peace conference opens in Paris (ends Oct. 15).

Nov. 4—Foreign ministers meet in New York to complete treaties (meeting ends Dec. 12).

1947

Feb. 10—Italian, Bulgarian, Rumanian, Hungarian, and Finnish peace treaties are signed in Paris.

Sept. 15—Five peace treaties come into force.

1950

June 25—Korean War begins.

1951

Sept. 4—Conference meets in San Francisco to draw up Japanese Peace Treaty.

1952

April 28—Japanese Peace Treaty comes into force.

1953

July 27—Armistice ends Korean War.

1954

Oct. 5—Free Territory of Trieste is divided between Italy and Yugoslavia.

1955

May 15—Austrian State Treaty is signed in Vienna.

July 27—Austrian treaty comes into force.

JOHN R. ELTING,
 Colonel, United States Army; Department of
 Military Art, United States Military Academy.

17. Costs, Casualties, and Other Data

World War II spread death and devastation throughout most of the world to an extent never before experienced. The loss of life can be only generally summarized; an attempt to express the value of property and livelihoods destroyed in terms of money is futile; the resulting sums reach astronomical figures that have little if any practical meaning.

Military Casualties.—Probably the best documented and most meaningful figures are the battle casualties. Those for the United States, Great Britain, and the Commonwealth nations are accurate; those for other nations, Allied or Axis, vary in reliability. Chinese figures are largely estimates because of the lack of documentation, information on Soviet losses has been given only grudgingly and in very general terms, and many records of the Axis nations were lost when those countries were overrun. The most accurate available figures are shown in Tables 1, 2, and 3.

Table 1—UNITED STATES ARMED FORCES TOTAL STRENGTH AND CASUALTIES IN WORLD WAR II, DEC. 7, 1941—DEC. 31, 1946

Service	Total strength	Battle deaths	Deaths from other causes	Wounds	Captured or missing
Army ²	11,260,000	234,874	83,400	565,861	135,524
Navy	4,183,466	36,950	25,664	37,778	2,429
Marine Corps	669,100	19,733	4,778	67,207	1,756
Coast Guard	241,093	574	1,345	955	
Total	16,353,659	292,131	115,187	671,801	139,709

¹ Not mortal. ² Includes Army Air Forces.

In utilizing strength figures, it should be noted that total strength means the total number of personnel belonging to the armed forces during the entire war, whereas peak strength is the greatest strength reached at any one time during the war. Several methods of classifying and computing casualties are in use, and other variations result from the differing periods covered by the various computations. Consequently, different reputable reference works sometimes show slightly different figures even for United States casualties. Non-battle deaths include deaths from accidents and disease.

Table 2—ARMED FORCES PEAK STRENGTHS AND BATTLE DEATHS OF THE PRINCIPAL ALLIED POWERS

Nation	Peak strength	Battle deaths
Australia	680,000	23,365
Belgium	650,000	7,760
Canada	780,000	37,476
China	5,000,000	2,200,000 ¹
Denmark	25,000	3,006 ²
France	5,000,000	210,671
Greece	414,000	73,700 ²
India	2,150,000	24,338
Netherlands	410,000	6,238
New Zealand	157,000	10,033
Norway	45,000	1,000
Poland	1,000,000	320,000
USSR	12,500,000	7,500,000
Union of South Africa	140,000	6,840
United Kingdom	5,120,000	244,723
United States	12,300,000	292,131
Yugoslavia	500,000	410,000 ²

¹ Casualties beginning with the Japanese invasion in 1937. ² Most of these casualties were suffered in guerrilla warfare that followed German occupation of the country. In the case of Denmark they include more than 1,200 merchant sailors in the service of the Allied powers.

Table 3—ARMED FORCES PEAK STRENGTHS AND BATTLE DEATHS OF THE AXIS POWERS

Nation	Peak strength	Battle deaths
Bulgaria	450,000	10,000 ¹
Finland	250,000	82,000
Germany	10,200,000	3,500,000
Hungary	350,000	140,000
Italy	3,750,000	77,494 ²
Japan	6,095,000	1,219,000
Rumania	600,000	300,000 ¹

¹ A limited number of these casualties occurred after the country joined the Allies. ² Of these, 17,494 were killed after Italy became a cobelligerent with the Allies.

Civilian Casualties.—Casualties among civilians were much less accurately recorded than military losses. In part, this was unavoidable because of the population shifts that took place as civilians fled before invading armies or the continual air attacks on major industrial centers, or were sent to Germany or the Soviet Union for forced labor.

Civilian casualties in the United Kingdom, slightly over half of which were inflicted in the London area, were as follows:

Agent	Killed	Seriously injured	Total
Aircraft bombs	51,509	61,423	112,932
V-1 (flying bombs)	6,184	17,981	24,165
V-2	2,754	6,523	9,277
Artillery fire	148	255	403
Total	60,595	86,182	146,777

Civilian casualties in the USSR have been placed roughly at 2,500,000 killed. The loss of population (including both military and civilian casualties) caused directly or indirectly by the war has been stated at 20,000,000. Air raids against Germany killed approximately 300,000 Germans and seriously injured about 780,000 more. Numerous additional casualties occurred during the Soviet invasion of 1944-1945, but no specific estimates are available. Japanese civilian casualties probably approached 500,000 killed and 625,000 seriously injured, plus a considerable number reported as missing after the fire raids and atomic bombings. In addition, about 360,000 Japanese captured by the Russians in Manchuria, Korea, and the Kuril Islands were still missing in 1950; a large number of them have never been accounted for. Chinese civilian losses are unknown but probably numbered several million.

Industrial Conversion and War Production.—In the final analysis, victory was won by the Allied powers' technological superiority—the ability to raise, arm, equip, move, and supply superior forces throughout the world, and through them to break up and destroy the technological resources (as well as much of the armed forces) of the Axis nations. Of all the Allies, it was the United States that possessed the raw materials, skilled manpower, and industries that made their victory possible. This potential American technological power, however, required precious time to change from peacetime to military production. The process of conversion, and of reconversion at the war's end, is illustrated in Table 4.

Table 4—UNITED STATES BUDGET EXPENDITURES, JULY 1, 1940–AUG. 31, 1945 (Billions of dollars)

Expenditures	1940	1941	1942	1943	1944	1945
Defense expenditures:						
War Department	\$0.9	\$7.3	\$29.5	\$46.5	\$49.2	\$34.0
Navy Department	0.9	4.2	14.0	24.6	29.6	19.4
Other departments	0.1	2.7	8.9	14.1	12.1	6.4
Total	1.9	14.2	52.4	85.2	90.9	59.8
Nondefense expenditures:						
Total	3.4	6.0	5.4	5.0	6.3	6.2
Total	\$5.3	\$20.2	\$57.8	\$90.2	\$97.2	\$66.0

Among the varied items purchased by United States defense expenditures were 57,027 medium tanks (9 different types), 676,433 two-and-one-half-ton, six-wheel-drive trucks (11 types), 1,054 eight-inch howitzers (48 of them self-propelled), 476,628 2.36-inch rocket launchers (bazookas), 4,014,731 Garand rifles, 106,658 gunner's quadrants, 4,072,000,000 rounds of .45-caliber ammunition, 57,488,000 wool undershirts, 116,000,000 pounds of peanut butter, 206,753 SCR-536 (Handie-Talkie) radio sets, 500,754 30-dose bottles of influenza virus vaccine, 7,570 locomotives (48 types), 23,510,030 military gas masks (2 types), and 3,898 B-29 (Superfortress) very heavy bombers. One of the best indications of the growing tempo of American military production during the war is the following data on machine-gun production, covering the period July 1, 1940–Aug. 31, 1945:

Year	.50 Caliber ¹	.30 Caliber	Year	.50 Caliber	.30 Caliber
1940	5,155	3,633	1943	641,638	188,311
1941	49,479	27,672	1944	677,011	121,771
1942	347,492	314,839	1945	239,821	62,777

¹ The increasing preponderance of .50-caliber machine guns reflects their growing use as aircraft and armored vehicle armament.

Shipping Losses.—Allied merchant shipping losses during the war were as follows:

Year	Number of vessels	Tonnage
1939	221	755,237
1940	1,059	3,991,641
1941	1,299	4,328,558
1942	1,664	7,790,697
1943	597	3,220,137
1944	205	1,045,629
1945	105	438,821
Total	5,150	21,570,720

Of the 5,150 Allied merchant vessels sunk, 2,828 were victims of Axis submarines, principally German. The parallel German submarine losses (revised according to the latest British Admiralty assessment) therefore furnish an interesting in-

dication of the gradual Allied success in antisubmarine warfare:

Year	Loss	Year	Loss
1939	9	1943	237
1940	24	1944	242
1941	35	1945	151
1942	87	Total	785

Other German naval losses included 2 battleships, 2 battle cruisers, 3 pocket battleships, 2 old battleships, 2 heavy cruisers, 5 light cruisers, 44 destroyers, and 86 light warships and armed merchant raiders, as well as 1,377 minor and auxiliary warships and approximately 550 landing craft. Japanese naval battle losses included 10 battleships, 20 carriers, 38 cruisers, 115 destroyers, and 119 submarines. The rapid disappearance of the Japanese merchant marine is shown in the tonnage available: 6.1 million tons in 1941, but 1.8 million tons in 1945.

British Commonwealth naval losses from Sept. 3, 1939, to Aug. 15, 1945, including Allied warships operating under British control, comprised 4 battleships, 2 battle cruisers, 5 aircraft carriers, 5 auxiliary aircraft carriers, 33 cruisers, 154 destroyers, 90 submarines, and 138 light warships and armed merchant cruisers, as well as 1,307 auxiliary and minor warships and 1,326 landingships and craft of all types. U.S. naval losses and gains during the war were as follows:

Type of vessel	Losses	New ships ¹
Battleships	2	8
Aircraft carriers	5	27
Escort aircraft carriers	6	110
Cruisers	10	48
Destroyers	71	349
Submarines	52	203

¹Part of this new construction, particularly escort aircraft carriers, was transferred to Great Britain as lend-lease material.

WORLD WAR II WAR CRIMES TRIALS. See WAR CRIMES.

WORLD WEATHER WATCH, a program developed in the early 1960's by the World Meteorological Organization (WMO) to improve the worldwide system of meteorological observations and forecasting. The goal of the World Weather Watch (WWW), which became operational in 1968, was to establish an efficient network of communications that avoided duplication in preparing meteorological analyses and prognoses, while providing weather services throughout the world with relevant data and background information on a daily basis. The WWW is made up of research centers and satellites in a coordinated worldwide network that constantly monitors the world weather situation.

WORLD ZIONIST ORGANIZATION, originally called the Zionist Organization, founded in 1897 by Theodor Herzl for the purpose of achieving the goals of Zionism. The WZO defined itself as "comprising all Jews who accept the Zionist program" as drafted by the First Zionist Congress in Basel, Switzerland. "Zionism," it stated, "strives to create for the Jewish people a home in Palestine secured by public law."

Within a year after the First Zionist Congress, local organizations were established in major European countries as well as in the United States and Argentina. At the Second Zionist Congress (Basel, 1898), 913 local groups were represented by 349 delegates. The congress was empowered to function as the supreme forum and legislative body of the WZO.

In the course of time, ideas concerning the precise form the Jewish commonwealth was to take in Palestine evolved from a rather vague "national home" into a demand for a Jewish state, as foreshadowed by Herzl in his book *The Jewish State* (1896). Early advocates of the Jewish state idea were the Zionist-Revisionists led by Vladimir Jabotinsky.

The work of the WZO was given impetus by the issuance of the Balfour Declaration on Nov. 2, 1917. A few weeks later (Jan. 5, 1918) the German government issued a similar pronouncement, welcoming a statement by the Turkish grand vizier Talat Pasa in support of a "flourishing Jewish settlement" in Palestine. With that, the WZO became a factor on the international political scene.

In 1929 the 16th Zionist Congress approved the establishment of an expanded Jewish Agency to enable non-Zionists to participate equally with members of the WZO in the building of a Jewish national home without identifying themselves with the political aspirations of Zionism.

The 23d Zionist Congress (1951), the first to meet after the establishment of the State of Israel, replaced the outdated Basel Program of 1897 with the Jerusalem Program. The new text declared: "The task of Zionism is to strengthen the State of Israel, to gather the exiles in the Land of Israel, and to guarantee the unity of the Jewish people."

In 1968 the 27th Zionist Congress redefined the aims of Zionism as "the unity of the Jewish people and the centrality of Israel in its life; the ingathering of the Jewish people in its historic homeland, Eretz Israel, through *aliya* [immigration] from all lands; the strengthening of the State of Israel founded on the prophetic ideals of

HISTORICAL PICTURE SERVICE

Much of the Columbian Exposition's simulated marble city, like its Court of Honor, fronted on artificial lagoons.

justice and peace; the preservation of the identity of the Jewish people through the fostering of Jewish and Hebrew education, and of Jewish spiritual and cultural values; the protection of Jewish rights everywhere."

In 1969 the Zionist General Council, the executive arm of the WZO, resolved to reconstitute the Jewish Agency for Israel by enlarging it so as to include representatives of Jewish communities worldwide. It was decided that of the delegates to the Assembly of the Jewish Agency, 50% should represent the WZO (including Israel), 30% the Jews of the United States, and 20% those of the rest of the world. An agreement was reached on the division of functions. Accordingly, the Jewish Agency was to conduct the activities supported by Jewish philanthropies throughout the world, such as absorption of immigrants and social, health, and educational programs, while the WZO would be responsible for public information, publications, education in the diaspora, and support of cultural institutions. The international headquarters are in Jerusalem.

RAPHAEL PATAI, *Editor of "Encyclopedia of Zionism and Israel"*

WORLD'S COLUMBIAN EXPOSITION OF 1893, an international exhibition held in Chicago, Ill., to commemorate the 400th anniversary of the discovery of America by Christopher Columbus. The exhibition was sometimes called the Chicago World's Fair. Authorized by Congress in 1890, the fair was dedicated on Oct. 12, 1892, by the vice president of the United States, and formally opened, after construction was completed, on May 1, 1893. With the push of a switch, President Grover Cleveland activated the electric power for the fair, turning on the incandescent lights and starting the electric fountains. Elec-

tricity, then unfamiliar to most Americans, was one of the fair's chief wonders. The fair closed on Oct. 30, 1893.

The fair was situated in Jackson Park on Chicago's southern lakefront, partly converted from swampland by landscape architect Frederick Law Olmsted. It extended about 2 miles (3.2 km) along the shore of Lake Michigan. Under the direction of Daniel H. Burnham, about 150 buildings, designed by such leading architects as George McKim and Richard Morris Hunt, were built around artificial lagoons. After some debate, the architects settled on a generally classical overall style, though Louis Sullivan and others had wanted to promote more modern, native architectural styles. Many of the building facades were constructed from material called staff, a composition of plaster of paris and jute fibers that resembled marble and lent the exposition its popular nickname, the White City. Especially noteworthy among the buildings was Sullivan's Transportation Building. The Fine Arts Building was later rebuilt in limestone to house Chicago's Museum of Science and Industry. Inside the buildings were mounted elaborate exhibits of industry, the arts, the states, and many foreign nations. The Midway Plaisance, an area devoted principally to amusement features such as George W. G. Ferris' newly invented Ferris wheel, drew much attention.

The exposition proved a success; the average daily attendance was 172,712, with a total attendance of over 27 million. Many worldwide organizations held congresses on the grounds. Fair expenditures were covered by the city of Chicago, a special minting of souvenir half-dollars as the gift of Congress, and by admission fees. Profits amounted to about \$1.85 million.

WORLD'S FAIRS. See FAIRS AND EXPOSITIONS.

WORM, a general term for many unrelated animals with soft, slender, elongated bodies lacking backbones, including some that have simple appendages for locomotion. The term refers to animals that retain a wormlike shape throughout life as well as the larvae (immature stages) of many insects, such as the maggots of flies and the caterpillars of moths. Worms range from less than .02 inches (0.5 mm) for some mesozoans to more than 10 feet (3 meters) long for giant earthworms. Most worms are benthic (bottom dwellers); a few are parasitic (living in or on other organisms).

Most of the approximately 30 major divisions or phyla of the animal kingdom have at least some wormlike representatives. The four major phyla of worms are Platyhelminthes (flatworms, such as flukes and tapeworms), Nematoda (roundworms, such as hookworms), Nemertea or Nemertinea (ribbon or proboscis worms), and Annelida (segmented worms, such as earthworms and leeches). Minor phyla that are believed to be related to the Nematoda include Gastrotricha, Rotifera (wheel animalcules), Nematomorpha (gordian or horsehair worms), Kinorhyncha, and Acanthocephala (spiny-headed worms). Relatives of the Annelida include members of the phyla Sipuncula (peanut worms) and Echiura (spoon or innkeeper worms). Groups whose affinity is still uncertain are Gnathostomulida (jaw worms), Entoprocta, Phoronida, Priapulida, Ectoprocta (bryozoans or moss animals), Brachiopoda (lamp shells), Chaetognatha (arrow worms), Pentastomida (tongue worms), Tardigrada (water bears), Hemichordata (acorn worms), Pogonophora (beard worms), and Mesozoa. Determining the "nearest relatives" of these groups continues to challenge biologists. These kinships are particularly significant in the case of the Mesozoa because some biologists regard these minute highly specialized organisms as representing an intermediate stage between single-celled and multicellular animals, while other biologists consider them as degenerate descendants of flatworms.

Worms are bilaterally symmetrical: their bodies can be divided into definite right and left sides that are mirror images of each other. In contrast, animals with radial symmetry, such as jellyfishes, have no definite right or left sides.

Bilaterally symmetrical animals develop in one of two ways. The fertilized egg divides repeatedly and forms a cluster of several hundred to perhaps a thousand cells. An opening, the blastopore, appears on the surface of the cluster. If the blastopore ultimately becomes the mouth of the adult animal, that animal is called a protostome (*proto*, "first"; *stoma*, "mouth"); if the blastopore becomes the anus, the animal is a deuterostome (*deutero*, "second"; *stoma*, "mouth"). All worm phyla are protostomes except the Hemichordata and the Chaetognatha, which are deuterostomes. Two other events during development—the formation of the body cavity (or its absence), and the tissues that line it—enable biologists to subdivide protostomes still further.

After the blastopore forms, cells arrange themselves into three groups or germ layers—ectoderm, endoderm, mesoderm—or fabric from which the adult animal forms. Mesoderm gives rise to many internal organs, all muscles, and the lining of the body cavity. A true body cavity, or coelom, is the space between the gut and the body wall, and it is completely lined with tissue

(Left) The acoelomate worms, such as the flatworm *Dugesia* of the class Turbellaria — shown in cross section and in full — are so named because they have no body cavity (coelom) between the body wall and internal organs. The space is instead filled with cells that derive from the embryonic mesoderm.

(Right) Pseudocoelomate worms have a coelom, but the gut lacks a mesodermal surrounding layer that would make possible peristalsis—that is, the muscular contractions that move food through the gut of coelomates. Pseudocoelomates also lack mesenteries, the membranes that support the gut of coelomates. The roundworm *Ascaris* of the phylum Nematoda is illustrated here.

(Left) Coelomate worms, along with all higher animal phyla, possess a true coelom. The gut-tube endoderm is surrounded by mesodermal tissue, which also lines the body's outer wall, and mesodermal mesenteries support a coelomate's internal organs. Seen in cross section and in full is *Lumbricus*, an earthworm of the class Oligochaeta of the phylum Annelida.

of mesodermal origin. In worms this cavity usually is filled with a fluid that functions as the skeleton. Annelids and their relatives have a true body cavity and are called coelomates. No body cavity develops in some protostomes (flatworms, ribbon worms, gnathostomulids). These animals are called acoelomates (*a*, "without"; *coelom*, "cavity"). A cavity does appear in roundworms and their relatives, but it is only partially lined with tissue derived from mesoderm. These animals are called pseudocoelomates (*pseudo*, "false"; *coelom*, "cavity"). The illustration shows the general organization of these three types of body structure.

The coelom itself develops in two ways. In one process, cells from the region of the blastopore divide and migrate inwardly; the resulting clumps of cells split and form the schizocoelom (*schizo*, "split"), which is typical of many coelomatus protostomes, particularly the annelids and their relatives. In the other process, the blastopore invaginates (folds inward) and forms

the primitive gut; cells from the innermost end of the gut form the mesoderm that eventually encloses an enterocoelom (*entero*, "gut"). Deuterostomes tend to be enterocoelous.

Other characteristics must be used to classify coelomates, acoelomates, and pseudocoelomates still further. For example, flatworms and gnathostomulids are acoelomates that have an incomplete digestive tract—that is, the same opening (the mouth) takes in food and ejects waste. Gnathostomulids differ from flatworms in the molecular structure of their flagella, which are oarlike structures that assist in movement. The structure of the head, jaws, and bristlelike sensory apparatus of gnathostomulids closely resembles those of certain pseudocoelomates. Thus gnathostomulids have features of both acoelomates and pseudocoelomates.

Ribbon worms are acoelomates that have a complete digestive tract (separate mouth and anus), and an eversible proboscis that captures food and, when armed, protects the worm. In these worms, "eversible" means that the proboscis lies in its cavity like a finger of a glove that has been pulled to the inside of the glove. The proboscis is then shot out when food is nearby. The "armed" proboscis of some nemerteans has barbs (stylets) that can pierce would-be predators and potential victims.

Among marine annelids and their relatives, the presence of a particular larva, the trochophore, is often cited as evidence for kinship, but larval forms may be similar for other reasons. The early development of these animals is strikingly similar and is the major reason for considering them as related groups.

Three phyla of uncertain classification are Pogonophora, Tardigrada, and Pentastomida. When pogonophorans were discovered, they were believed to be deuterostomes. Now they are considered intermediate to protostomes and deuterostomes or even as a completely separate evolutionary line. The discovery of giant pogonophorans, made when the submersible *Alvin* descended to the Galapagos Rift, may provide zoologists with the information needed to determine the status of these worms. Tardigrades superficially resemble gastrotrichs, and may be pseudocoelomate. They fascinate biologists because they can survive near absolute zero (about -273°C or -459°F). Pentastomids are probably related to the arthropods, in which case they should not be considered true worms.

More than a century ago, Charles Darwin showed how beneficial earthworms are to farmers in loosening and conditioning the soil. And several species of parasitic worms have long been recognized as causes of diseases in humans and in domesticated plants and animals. Worms have become increasingly important in basic research and medicine. For example, toxins from ribbon worms show promise as effective agents against certain cancers. The brain and nervous system of leeches are particularly well suited to studying how nerve cells function in groups. Rotifers have been used to study the aging process, and other pseudocoelomates are used in genetic research, both at the chromosomal level and to learn how a single nerve cell controls several different tissues.

WORM GEAR. See GEAR.

WORM LIZARD, a cylindrically shaped reptile, usually limbless, adapted for life underground. The skull is specialized for digging, with closely sutured bones. The long body has 85 to 156 vertebrae, but is limbless except in the species of *Bipes* in Baja California, which has well-formed front legs. The tail and head are blunt, the latter sometimes having a wedge-shaped tip. The scales are small and arranged in narrow rings. By moving these rings the animal can travel forward or backward in its self-made tunnel, like an earthworm. The four families, usually placed in a separate suborder, the Amphisbaenia, include fossil members from Paleocene time and 140 living species. Numerous of these species occur in South America, the West Indies, western Asia, and Africa, but only one each in Spain and Florida. The only species native to the United States is *Rhineura floridana*, which lives in central and northern Florida. It feeds on termites, spiders, and earthworms, and seldom attains a length of 12 inches (30 cm). Other species may be an inch in diameter and up to 30 inches (75 cm) long.

Coauthor of "General Zoology"

WORM SNAKE, a small, harmless, semiburrowing snake (*Carphophis amoenus*) of the deciduous forest region in the eastern and midwestern United States. Adults average about 9 inches (22 cm) long and are about $\frac{1}{4}$ inch (0.6 cm) in diameter. The head is rounded in outline but wedge-shaped in side view, without a distinguishable neck. The short tail has a sharp tip. The smooth, glossy dorsal scales are in 13 rows. These snakes are brown with a pink belly in the East but black with bright red bellies west of the Mississippi River.

Worm snakes are among the most common snakes in many localities but are seldom seen because of their secretive habits. They are most active from late afternoon to midnight but usually are found only when exposed by turning over rocks or logs. They largely feed on earthworms. Two to five eggs are laid in June or July. These are surprisingly large for such small snakes, being almost 1 inch (2.5 cm) long and $\frac{3}{8}$ inch (1.75 cm) in diameter. They usually hatch in September or early October, and the young are only about 4 inches (10 cm) long at birth.

WORMS, worms, a city in West Germany, in the state of Rhineland-Palatinate, on the left (west) bank of the Rhine River, 9 miles (14 km) north of Mannheim. The manufacture of machinery and leather products, sugar refining, canning, and iron and chemical industries are important economic activities. In addition, there is a good river port, and in the immediate area fine Rhine wines are produced. The most famous of these, Liebfraumilch, is named for a church (Liebfrauenkirche) on the northern edge of the city.

The Romanesque cathedral (1018–1234) has a choir at either end, each flanked by two tall round towers and surmounted by a lower one. Other points of interest are the Romanesque St. Paul's Church, the oldest parts of which date from 1016; St. Andrew's Church (11th–12th century); the late Romanesque Church of St. Magnus; and the late Gothic Liebfrauenkirche. The

Worms' double-apsed cathedral is one of the finest examples of German Romanesque architecture.

Jewish community is one of the oldest in Germany, dating from 588; original elements retained in the reconstructed synagogue are from the 12th and 13th centuries.

History. The original Celtic name of the place was Borbetomagus. In 14 B.C. the Romans established a fortification here among the Germanic Vangiones, who soon merged with the remaining Celts and the Romans. There were numerous invasions by Germanic tribes from across the Rhine, and toward the end of the Roman period the Emperor Honorius (reigned 395–423) established a Burgundian kingdom centered at Worms to act as a buffer state. The Burgundians became Arian Christians and probably used Ulfilas' Bible. Under Gundicar (Gunther of the *Nibelungenlied*) they revolted against the Romans, but the Roman general Flavius Aëtius with his Hun allies nearly wiped them out in 436.

By the 6th century the city was known as Wormatia, and in Carolingian times it was of considerable importance; Charlemagne held a number of diets here. Worms fought consistently to maintain its independence from the bishops and usually sided with the emperor, as it did with Henry IV (reigned 1056–1106) during the investiture struggle. The emperors rewarded the city with special privileges, so that Worms became in effect the first free city of the Holy Roman Empire, a status confirmed in 1273.

The most famous of the imperial diets held in Worms was that of 1521, before which Martin Luther appeared (see WORMS, DIET OF). The city was pillaged several times in the Thirty Years' War (1618–1648), but the worst destruction was caused by Louis XIV's general, Ezéckiel de Mélac, who burned it in 1689. So complete was the destruction that the city council had to

remove to Frankfurt am Main and did not return for nine years. In 1797 the city became French, but in the general settlement of 1816 it was awarded to Hesse-Darmstadt (from 1866 known as Hesse).

During World War II, Worms suffered approximately 50% destruction, but after the war reconstruction proceeded rapidly, with an accompanying improvement even of some historic structures, such as the Church of St. Magnus. In the redivision of state territories in 1945, the city was included in the new State of Rhineland-Palatinate, which became a part of the Federal Republic of Germany (West Germany) in 1949. Population: (1984) 72,610.

WORMS, Concordat of. See CALLISTUS II; INVESTITURE CONTROVERSY.

WORMS, Diet of (1521), worms, an imperial diet (assembly) convoked by Charles V, newly elected Holy Roman emperor, in the city of Worms, Germany. It was the first of his reign. On the agenda, besides many political, military, and financial topics, was the case of Martin Luther. A clause in the emperor's contract with the German princes provided that, before confirming the sentence of a foreign court upon a German subject, he must give the accused a hearing. Luther had been excommunicated by Pope Leo X on Jan. 3, 1521, and Charles was urged by the Curia to impose the imperial ban upon him also. Luther's prince, Frederick III the Wise of Saxony, insisted upon a hearing.

Luther appeared before the assembled diet and on April 18, 1521, publicly refused to recant his views, unless "convicted by Scripture and plain reason"; "my conscience," he stated, "is captive to the Word of God." On May 25, just before the adjournment of the diet, Charles formally put the imperial ban on Luther by publishing the Edict of Worms, which he had signed on May 8. Thus Luther was outlawed, but the verdict was never executed.

WILHELM PAUCK, Author of
"The Heritage of the Reformation"

WORMWOOD, wûrm'wôd, an aromatic herb (*Artemisia absinthium*) of the sunflower family, the source of oil of wormwood. It is a perennial, commonly 2 to 4 feet (0.6–1.2 m) tall, with clustered stems and silvery gray herbage. The leaf blades are up to about 4 inches (10 cm) long and are divided into numerous blunt or rounded small segments, the basal leaves being long stalked and larger than those of the stem. The numerous flower heads, which are scattered along branches that have reduced leaves, are small, yellowish, and individually rather inconspicuous, being hardly a quarter inch (0.6 cm) wide.

Oil of wormwood, a bitter, volatile, brownish green oil, is obtained by steam distillation from the dried leaves and tops. It is composed of a mixture of substances, including thujyl alcohol and acetate, thujone, phellandrene, and cadinene. It is used principally as the characteristic flavoring ingredient that distinguishes absinthe from all other alcoholic liquors. The deleterious effects of prolonged use of oil of wormwood have led to the outlawing of absinthe in some countries. Oil of wormwood was formerly used also as a tonic, appetizer, diuretic, anthelmintic (to expel or

Roche

Wormwood (*Artemisia absinthium*).

destroy intestinal worms, whence the name), antimalarial, moth repellent, and as an ingredient of liniment, but these uses have largely disappeared.

Wormwood is native to Eurasia and has been introduced into North America, where it occurs as a casual weed in waste places in the northern United States and southern Canada. It is grown commercially in limited quantities in Europe and also in the United States, as in Michigan, Wisconsin, and Oregon. The name wormwood is often applied also, by extension, to various other species of *Artemisia*, and even to some plants of superficially similar appearance but quite different properties and relationships, such as *Corydalis sempervirens*, called Roman wormwood.

ARTHUR CRONQUIST,
Curator, The New York Botanical Garden.

WORSHIP, wŭr'shĭp, divine honors paid to God, specifically words addressed to Him, either said or sung, or acts performed in His honor. The term is derived from Anglo-Saxon *weorthscipe*, "worthship," the recognition or acknowledgment of worth or worthiness (compare Luke 14:10, Authorized Version, "Then shalt thou have worship," where Revised Standard Version reads "be honored"). In Judaism and Christianity, and in most other religions, divine worship is the highest expression of faith and devotion, and its chief component is prayer or praise.

The authentic pulsebeat of any religion is felt in its worship; to this all other elements, including its creed, theology, and organization, are secondary and dependent. In worship the sense of divine presence, and the attempt to approach God, to ascertain and yield to the divine will, are the central realities, hedged in mystery and filled with power. Sacraments, sacrifices, special offerings and dedications, festivals, supernatural cleansing and forgiveness, and the quest for divine power and grace—all these find their center action in worship. Thus in early Greece

and early Israel the festivals were essentially joyful celebrations (as at the harvest) of the divine presence and favor: God (or the god) was actually with his people, among them, spreading the blessings of his divine presence and goodwill. Such observances sometimes became little more than country fairs or secular feasts, but the religious significance was never wholly lost.

The early Christian church distinguished between the service of worship centered in "the Word" (the reading, study, and exposition of Holy Scripture) and that centered in the Sacrament (the Lord's Supper), where prayer and action were combined with reading. Both types had their antecedents in Judaism, the study of Scripture in the synagogue service, the sacramental or sacrificial rite in the worship of the Temple. Both types are reflected in modern Protestant and Roman Catholic worship: the Breviary Offices or "Hours," combined (for example, in Lutheran and Anglican worship) in the services of Morning and Evening Prayer, and the sacramental service of the Mass, Lord's Supper, or Holy Communion. The same is true of Orthodox Eastern worship, where the lectionary element (reading from Holy Scripture) is combined at great length with the central liturgical act of the Mass (the Holy Mysteries). Still other types of worship are found, not only in other religions but even in Christianity, where, for example, the Society of Friends (Quakers) have only the service of prayer and the reading of Scripture, and no sacraments.

The charge of "formality," sometimes brought against the classic types of Christian worship, could be brought against any kind of religion, even the most "inward" or inarticulate. On the other hand, objective or fully expressed worship is the normal means of access to the divine presence and the source of religious strength and inspiration to countless believers, from the simplest adherents to the most devout and consecrated saints.

FREDERICK C. GRANT,
Emeritus Professor of Biblical Theology, Union
Theological Seminary, New York City.

WORSHIP, Freedom of, the freedom to perform acts of worship or to conduct activities associated with religion without legal restraint. This article deals with the application of the principle in the United States. For the history of the subject in other countries, see CHURCH AND STATE; DECLARATION OF INDULGENCE; INQUISITION, THE; LIBERTY; TOLERATION; sections on religion in articles on individual countries; and separate articles on individual religions.

The beginnings of freedom of worship in America were highly ambiguous. Many of the early colonists left England to obtain this freedom, but they were generally unwilling to grant the same freedom to those whose patterns of worship differed from their own. The change came only gradually; even after the Revolution some particular Protestant church had special privileges in many of the states, and Roman Catholics and Jews were widely subject to legal disabilities. Since 1800, however, the growth of freedom of worship has been spectacular, both in its legal protection and in community practice. This development has disproved the assertion often made that freedom of worship thrives only where worship is considered unimportant; in the United

States the extension of religious freedom has been accompanied during both 19th and 20th centuries by the growth of a strikingly varied and vigorous religious pluralism.

Constitutional Basis.—In the original Constitution of the United States, the only clause relating to religion was that of Article VI forbidding religious tests for any office “under the United States.” In the Bill of Rights, however, the 1st Amendment added this prohibition: “Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof.” This provision originally had no effect on establishments and restraints in force in the states, except to protect them from congressional interference. In recent decades, however, it has become settled that freedom of worship is part of the “liberty” protected against state action by the “due process” clause of the 14th Amendment. It has also been decided that the 1st Amendment provisions in their entirety have thus been made applicable to the states. Historians disagree, however, concerning the original understanding, both of the “no establishment” clause and of the “due process” clause in relation to religious freedom.

The “free exercise” and “no establishment” clauses are closely related; many measures which violate one necessarily violate the other also. For example, when the Supreme Court of the United States in 1961 struck down a Maryland state constitutional provision that officeholders must declare belief in the existence of God, the court considered that the requirement operated to “establish” theistic religion and also that it restrained the freedom of adherents of nontheistic religions such as Buddhism, of movements such as Ethical Culture, or of beliefs such as secular humanism.

Attempts are often made to express the effect of the two clauses in a single general principle. Perhaps most frequently urged is the principle of separation of church and state, requiring the insulation of religion from all exercise of state power. Sometimes it is said that what the 1st Amendment forbids is all legal concern with religion, all legal distinctions drawn in terms of religion, whether their effect upon worship would be

favorable or unfavorable. A third general principle is that of neutrality toward religion, assuring “external” freedom of worship by forbidding government restraint and “internal” freedom of worship by forbidding government support. No one of these principles can consistently explain all aspects of American law and practice in church-state relations. Some of the points at which the principles differ in their practical application are noted in the sections that follow. The neutrality principle seems preferable in that it affords the greatest protection to freedom of worship.

Before considering further the constitutional limitations, it should be noted that full enjoyment of religious freedom requires not only freedom from government action but also freedom from the social pressure springing from intolerance. Most dramatic among many signs of the spread of religious tolerance in the United States was the election in 1960 of a Roman Catholic (John Fitzgerald Kennedy) as president. Notwithstanding such signs, toleration is by no means unlimited, and its limitations are often revealed in the sharp controversies which have been touched off by some of the court decisions expanding the legal protection of freedom of worship.

“Free Exercise” of Religion.—Neither federal nor state authorities can regulate religious worship as such, but constitutional protection of the free exercise of religion does not mean a broad religious exemption from general laws imposed for the public health, safety, or morals. Freedom of worship has been held not to justify the early Mormon practice of plural marriage, nor does it cover rites involving the use of narcotics or the handling of poisonous snakes. Compulsory high school attendance has been enforced against the religious convictions of the Old Order Amish; religious scruples against blood transfusion have been overruled where lives of children were at stake; and child labor laws have been applied to children selling religious literature on the street. On the other hand, religious freedom has been held to require exemption from compulsory flag salutes in public schools and also exemption from permit requirements for the use of streets and parks for proselytizing.

Freedom of worship was one of the main reasons for the Puritans settling in the New World. Here they are seen leaving Holland.

The Bettmann Archive

General principles of church-state relations are of little help in working out the limits of the "free exercise" clause. The decisions have apparently involved a weighing of the importance of the purposes served by the various regulations, on one hand, against the value of unrestricted freedom of worship, on the other. The difficulty of drawing a balance is illustrated by a case on which the Supreme Court twice divided without a majority decision on the main issue: a mail fraud prosecution of a cult leader for making false claims of spiritual powers with intent to deceive.

"Establishment of Religion" Clause.—This clause obviously forbids giving to a particular church a preferred position. While this may have been the extent of its original meaning, the clause has been interpreted to forbid also the giving of "aid to all religions." The position that churches should be kept free from government aid had been eloquently supported by James Madison in his *Memorial and Remonstrance Against Religious Assessments* (1785). This document was an argument against a bill in the Virginia legislature to levy a tax for the support of "Teachers of the Christian Religion." Taxpayers were to have the privilege of designating the particular "society of Christians" to which the tax should be paid, and for those who made no such designation the tax proceeds were to be applied by the legislature "for the encouragement of seminaries of learning." It is agreed that the 1st Amendment forbids any such legislation, even if non-Christian bodies were included and even if persons who have no religious affiliation were exempt.

Interpretation of the "no establishment" clause as forbidding nondiscriminatory aid raises questions concerning the tax exemptions which have been firmly entrenched in American practice from the beginning. Some exemptions are clearly defensible, such as the federal income tax deduction for religious charities. Since the tax code permits deduction of contributions to nonreligious charitable and educational enterprises, permitting deduction also of contributions to similar religious enterprises represents no departure from the neutrality principle. Some laws, however, grant to churches a special tax exemption not extended to similar nonprofit organizations. Such exemptions operate as subsidies of religion, and they represent historical survivals which are difficult to defend now that it is agreed that direct appropriations to churches would be improper, however impartially they might be administered and however highly the churches may be valued for their contributions to social morality.

Protecting Freedom of Worship.—In other areas also, exemptions designed merely to protect freedom of worship are sometimes attacked as laws "respecting an establishment of religion." For example, many Sunday closing laws exempt those whose religious beliefs require them to close their places of business on some other day. The closing laws themselves are sustained only on the ground that they are not now intended to serve religious ends. It is now settled that the exemption of merchants who observe the seventh-day Sabbath is constitutional, although such exemptions are clearly inconsistent with both the separation principle and the principle forbidding legal distinctions in terms of religion. In granting such exemptions, legislatures are recognizing the fact of religious differences and the inequality of burden which would result from laws which con-

tain no exemptions. The drafters are thus not trying to aid religion, but to maintain religious neutrality and to avoid restricting freedom of worship. Exemptions of clergy and divinity students from military service are defensible on similar grounds. While the "free exercise" clause does not require Congress to grant such exemptions, neither does the "no establishment" clause forbid them.

The same justification applies in many other situations where strict separation of church and state is not observed. For example, if the United States Defense Department were required to have nothing to do with worship, the result would be a limitation of the religious freedom of service personnel on Army posts and naval vessels. Government provision of facilities for worship is not a policy designed to promote religion but a neutral policy of avoiding unnecessary restraint of freedom of worship. Such government action extends the freedom of worship beyond the area of the constitutionally protected "free exercise" of religion.

There are many other areas in which the government has made no attempt at strict church-state separation but, on the contrary, has shown active concern for the religious freedom of those over whose lives it has taken a large measure of control. Two such areas have been the Indian reservations and government-owned communities like those established around atomic installations. Similarly, public urban redevelopment programs have often involved government action making land available for religious as well as nonreligious institutions.

Perhaps the clearest example of the impracticability of complete church-state separation is in the situation where a child becomes the ward of the state. Whether he is placed in a public or a private institution or in a foster home, the matter of religious upbringing cannot be ignored, and similar problems arise in many adoption cases. The resulting problems are by no means simple, and they often involve bitter religious controversy. However, it would be impossible without practical hostility to religion to insulate courts and welfare authorities from religious concerns. The Constitution does not require (to quote the language of the Supreme Court) "a callous indifference to religious groups. That would be preferring those who believe in no religion over those who do believe."

Public Education.—In 1962 the Supreme Court held that the "no establishment" clause prevents a state from prescribing a prayer for use in public schools, although its authors had attempted to avoid sectarianism. Even with provisions excusing individual pupils who object, any prescription of worship in public schools seems clearly an effort to inculcate religious belief and practice; it is therefore inconsistent with the maintenance of state neutrality toward religion. This decision had been preceded by two cases involving arrangements for released-time instruction in sectarian religion, invalidating a program which used public school buildings and sustaining one which avoided this feature.

Programs condemned in these cases should be distinguished from proper use of the Bible in public schools in the same way as other books are used, and from objective teaching about religion which is not designed to induce belief or habits

of worship. State universities thus may have departments of religion and courses in particular religious traditions. (Thomas Jefferson, author of the phrase "a wall of separation between church and state," even included sectarian schools of divinity in his plan for the University of Virginia.)

At the elementary school level, it may be difficult to devise ways of teaching about religion while maintaining neutrality. Ignoring religion, however, involves an equal danger of violating neutrality by inculcating secular humanism. Education in a democracy should include, in any event, teaching about the value of freedom of worship. It is of vital importance for a democracy that its citizens have deep-rooted belief in the dignity of man and his capacity for growth in responsible freedom. It is therefore important that pupils should learn respect for the ways in which different groups find sustaining roots for such belief in various religions and philosophies.

Religious Schools.—In 1925 the Supreme Court held that a state may not require all children to attend public schools. The decision was made at the suit of a military academy as well as a parochial school and was not placed on the ground of religious liberty. Subsequent problems have related principally to financial support. In the United States, religious schools have not derived any of their support from tax funds, contrary to the practice in certain other countries; proposals for federal aid to education have periodically raised controversies over whether religious schools may be included in such programs without violating the "no establishment" clause. Students in religious schools have shared in a number of federal programs, including those relating to school lunches, veterans' education benefits (the so-called G.I. Bill), national science scholarships, and the education of congressional page boys. None of these programs, however, has come before the Supreme Court.

The court held in 1947 that a state provision for reimbursing the bus fares of parochial school pupils did not violate the "no establishment" clause. The court interpreted the clause to forbid general aid to religion but added that "... we must be careful, in protecting the citizens of New Jersey against state-established churches, to be sure that we do not inadvertently prohibit New Jersey from extending its general State law benefits to all its citizens without regard to their religious belief." The court thus applied the neutrality principle and rejected the requirements of strict segregation. By the same reasoning one can justify broader efforts to avoid religious discrimination in financing the costs of education in nonreligious subjects. The failure of many Americans to accept this point may reflect an unwillingness to support full freedom of those who believe in parochial schools.

Constitutions of many of the states have provisions concerning religion which are more specific than those of the 1st Amendment. A common clause is one which in varying terms forbids the use of public funds for religious schools. These clauses are sometimes interpreted as forbidding state action which the federal Constitution leaves the states free to take; thus a number of state courts have invalidated appropriations for bus transportation or textbooks for pupils in parochial schools. Other courts, however, have held that

such appropriations involve merely nondiscriminatory aid to students and not support of religious schools within the meaning of their constitutional prohibitions. State scholarship programs have often included students in denominational colleges.

Prospects.—The special contribution of the United States to the development of freedom of religion has been the policy of neutrality—particularly two aspects of this policy. These aspects may be expressed in two propositions which are reflected (however incompletely) in American law and practice. The first is the proposition that worship is free only when it stands without the backing of government. The second proposition marks the limit of the first: it is not an improper backing of religion for the government to express its concern for freedom of worship by measures which merely neutralize what would otherwise be restrictive effects of government action.

Wider acceptance of the first proposition probably will come about only through deeper understanding of the reasons for religious freedom. Freedom of worship is not merely a practical policy expedient for keeping peace in a pluralistic society; it is an integral part of religious belief. When government punishes heresy, it not only violates the freedom of the heretic but also renders unfree the religious commitment of the orthodox. The very nature of worship requires that worship be free. Modern writers in increasing number are expounding such views—not only writers in the tradition of "liberal religion," but also Roman Catholics and orthodox Protestant and Jewish spokesmen.

Distrust between religious groups sometimes blocks the acceptance and application of the second proposition (that government may affirmatively promote religious freedom). For example, hesitation to support arrangements that would increase the religious freedom of groups committed to parochial schools sometimes reflects distrust as to the devotion of one or more of these groups to the principle of religious freedom. Wider support for legislation maximizing freedom can be expected only as it becomes widely apparent that the major religious groups have in common a trustworthy belief that worship should be free.

WORSHIP, Household. From immemorial time mankind has communed with the Deity not only in public religious services and private devotions but also through domestic worship performed in dwellings and conducted usually by the head of the household. Household worship includes such rites as sacrifice, prayer, song, feast, purification,

adoration of holy images of various types, and reading from or recital of sacred literature. In popular practice, domestic devotions have been extended to (1) worship of the family's deceased members, principally its progenitors (see ANCESTOR WORSHIP); (2) propitiation of celestial phenomena and of various forms of animal and vegetable life, including their personification (see ANIMAL WORSHIP; NATURE WORSHIP; MYTHOLOGY); and (3) invocation of divine benediction at the family's meals, usually before eating, a practice common among Jews and Christians. Although there are exceptions, household worship generally lingers longer in rural districts, where life is more leisurely and the family is more cohesive, than in urban communities, where public places of worship are more numerous and accessible, people are more sophisticated, and the tempo of life is swifter. Since most literature dealing with man's relation to the Deity is concerned primarily with corporate or public worship, evidence for domestic, as distinct from personal and private, worship, depends principally upon incidental and casual references.

Among tradition-minded families throughout the Mediterranean area, ancient household devotions persisted until they were submerged by the rising tide of Christianity, which became the official religion of the Roman Empire in 380; such earlier domestic rites as survived thereafter in the Near and Middle East and North Africa succumbed to the Islamic conquest after the mid-7th century. There is scant evidence about household worship in northern Europe before the Christianization of that region began in the 7th century, in the Americas before the 15th century, or in sub-Saharan Africa and the Pacific islands before the mid-19th century. But it is certain that whatever household worship existed among these peoples, its principal purpose was to win divine favor for the family and to avert demonic influences. In the Far East, domestic worship in China, Japan, and India has descended from antiquity to modern times without serious interruption, surviving principally among the populace in rural areas.

Ancient Babylonians and Egyptians.—Our knowledge of domestic religious services among ancient peoples, apart from classical and Oriental practices, is imperfect, because the literary and archaeological materials available contain little data on the subject. It is believed, for example, that household worship, involving prayers and offerings to departed ancestors, existed among the Babylonians, although the spirit of Babylonian worship apparently asserted itself rather in communal or private worship. There is abundant evidence about private devotions, including poses assumed, gestures made, oblations offered, and prayers said or sung, but this bears largely upon the worshiper in the presence of his deity in a temple and is not absolutely applicable to domestic worship.

In Egypt, a sepulchral mural portrays a peasant with his family praying in his field—a variation of worship in a house—before a sycamore tree, beside which they have placed offerings of fruit, bread, and water. This scene is indicative of one form of nature worship, which was widespread among primitive people. Several representations of persons adoring their domestic animals, such as cattle, cats, and birds, exist. Snakes, as protectors of the household, were propitiated with offerings of milk. The ordi-

nary house had a shrine—a wooden cupboard or a small niche in the wall—containing clay or bronze miniature figures of various deities and sacred animals, with a lamp burning before the images. Domestic worship was practiced before such shrines, but we know little about the ritual.

Jews.—Among the ancient Hebrews, the Sabbath was from remote antiquity a day devoted to acts of worship. In the Hebrew household the Sabbath's normal three meals were preceded by paternal sanctification and followed by the singing of hymns. Preeminent among the household devotions was the celebration of the Passover, instituted on the eve of the Israelite exodus from Egypt (Exodus 12:3–14) in the 13th century B.C., with which was associated the Seder or family feast, religious in character. Although changed civil and economic conditions have wrought minor changes in these celebrations, the modern Orthodox Jewish family's observance of the Sabbath and Passover remains basically the same as it was 30 centuries ago. See also JEWISH HISTORY AND SOCIETY—19. *Religious Traditions and Customs*. PASSOVER; SABBATH.

Persians.—The Persian householder, surrounded by his family, worshiped the hearth fire daily by sacrificial offerings of fragrant fuel. Zoroastrianism held that fire was a holy flame, and the worshiper prayed that it might ever burn in his house. The hearth fire, in return for proper adoration, blessed the family with life and valor, holiness and wisdom, cattle and children. Sacrifices were made also to certain celestial divinities, such as Sraosha, who befriended the family; Mithras (Mithra), who rewarded the truth-speaking family with material blessings; and Haoma, who conferred health and happiness on the household. The family turned for protection also to the Fravashis, guardian spirits of the dead; with oblations, sacrifices, prayers, and hymns the family invoked their benedictions on the anniversary of a member's death. The Fravashis consequently blessed the household, protected it from enemies, and caused the householder's children and cattle to prosper.

In modern Iran, some 20,000 Gabars still practice Zoroastrianism and follow the ancient rituals, with a room in a quiet part of the house set aside as the fire temple. For the Parsis, Indian followers of Zoroaster, numbering more than 100,000 and settled near Bombay, the ceremonial fires are more usually kept in special buildings, from which nonbelievers are generally excluded. The Parsis believe that the Fravashis revisit the homes of their descendants during the 10-day festival in their honor at the end of the year.

See also ZOROASTRIANISM.

Ancient Greeks.—Among the Greeks, household worship was centered about the hearth. Hestia, goddess of the hearth, was propitiated at the beginning of the family's meals by offerings of small portions of food. The Good Daimon, believed to be the good luck of the house, was worshiped by pouring a little wine onto the floor whenever wine was drunk. At banquets, which were concluded by wine parties, the start of the drinking bout (Gr. *symposion*; Lat. and Eng. *symposium*) was signaled by pouring three libations: to Zeus, king of gods and men; to the heroes; and to Zeus Soter (Zeus the Savior), a shadowy domestic divinity. Exact recital of ritualistic words was required; otherwise the rite was in-

valid and its repetition was necessary. Household worship was indicated particularly when a member of the family undertook an important activity outside the family circle, especially when departing on a hazardous journey or for war.

Ancient Romans.—In Rome the *paterfamilias*, or father of the family, was the household priest and conducted the domestic devotions. Devout Romans prayed and sacrificed every morning, but the customary time for familial worship was toward the end of the daily dinner, when offerings of food and drink were made to Vesta, goddess of the hearth; to the family's tutelary deities, the Lares; and to the guardian spirits of the family's larder, the Penates. The reverence accorded to these divinities gave to every religious Roman's house something of the sanctity of a temple. Their miniature images were enshrined near the hearth in a niche, which might also contain statuettes of deities worshiped privately by members of the family. Propitiation of the Lemures or Larvae, the spirits of the dead, was another aspect of Roman domestic worship. See also LARES; LEMURES; PENATES.

Chinese.—The Chinese worshiped particularly such household divinities as the housegate god, the door god, the hall god, the god of the walls, and the kitchen god, whose images were enshrined usually in the main room of the house. On New Year's Day the head of the household led his family in worship of these deities, after which the family feasted on delicacies. Family sacrifice to its ancestors was by oblations, which might be cakes, cereals, melons, water, wine, flowers, incense, jewels, and small animals; such devotions were performed before tablets containing the ancestors' names. Funeral services in the house also called for common participation by the family, which prayed and sacrificed for the deceased member's well-being in the spirit world. Today the ancestral shrine with its inscribed tablets is still the center of family life in religious Chinese homes. Food sacrifices are offered there, proposals of marriage received by a girl's father, and other important announcements and decisions made, in the presence of the ancestors.

Japanese.—The family sanctuary was almost universal in Japan. The household was inspected periodically by the neighboring priest to see that it had a proper place of worship. This sanctuary was the so-called god shelf, on which were placed likenesses of such deities as the family favored. Worship was periodical and at the family's preference; but the observance of New Year's Day called for a special religious ceremony by the family, which offered prayers, oblations, and incense to win divine protection throughout the year. Funeral services were conducted in the house and were considered an aspect of household worship because the surviving relatives prayed for the welfare of the deceased's spirit. In modern Japan believers still worship at the home's god shelf, where sacrificial offerings are made and special occasions are celebrated.

Hindus.—The ancient Hindus worshiped Jara, goddess of the house, with perfumes, flowers, incense, and food placed before her painted image; in return, she promised children. An image of Naga, a harmless snake, was worshiped with sugar, rice, and millet to divert venomous serpents from the house. In some sections of India a

family fetish, a wooden stake, was set in the ground outside the house door and was worshiped periodically. Hardly a household was without its tutelary deity, usually represented by some crudely carved likeness or symbol in homely shrines or over doorways. This divinity was worshiped as one who delivered the family from calamities, actual and potential, believed to be due to demons. Purificatory rites, consisting of prayers, ablutions, libations, and oblations, were performed daily and particularly on occasions of marriage, birth, and death. The hearth fire was worshiped daily (morning and evening) by the family, which prayed, sang hymns, and fed the sacred fire with wood, rice, and butter. To a pious Hindu, every 14th day was a high and holy day, marked by special family observances. Sacrificial cakes, prepared from rice and butter, were cast into the hearth fire in the names of various deities, while sacred songs were sung.

Each house had a small wooden temple as a sacred shrine for the household divinities, generally five consecrated symbols representing the chief Hindu gods. These symbols were usually stones: black for Vishnu, white for Shiva, red for Ganesha, multicolored for Shakti, and a crystal for the sun. Before these stones, arranged on a circular metal disk, domestic worship was celebrated daily after proper purification of the family members. It consisted of at least 16 stages, during each of which a sacred verse was recited. Offerings included water, milk, honey, butter, porridge, and assorted cereals. In India today an image or symbol of a tutelary deity is enshrined in most homes and a priest or member of the family conducts the traditional domestic rites before it.

Modern Christian Practices.—Apart from the Jewish practices previously described, the domestic worship with which most people in English-speaking countries are now familiar is the Protestant Christian household service, which originated during the Reformation, when the principal reformers of the 16th century conducted household worship as an adjunct to congregational worship even after the Protestants had their own churches. In modern times, the assembly of the household about the so-called family altar (as the service commonly is called) occurs principally in the families of Protestant clergymen, either daily or on Sunday, usually before or after breakfast, but occasionally in the evening. Here and there among the pious laity such services also occur, ordinarily only on Sunday. The worship is short and simple. It includes normally, although exceptions and variations exist: (1) reading of a Biblical passage, customarily by the father of the family, (2) an extemporaneous or occasionally set prayer, ordinarily also by the father; and (3) singing a hymn, with or without musical accompaniment, by all the family. Sometimes the reader from the Bible or another (older) person will offer a brief meditation on the reading by demonstrating its pertinence to historical or modern times.

In the British Isles, services in the home became common after the Continental Reformation and were widespread in Scotland, where they still are strong among Presbyterians. Some vestiges remain in Wales and in Northern Ireland and among Anglican churchmen in England. Household worship in the United States can be traced to the colonial period, particularly in New England, where the Pilgrim Fathers introduced it in

Mansell Collection, London

This scene of a Scottish family's home worship was inspired by Robert Burns' *Cotter's Saturday Night*.

1620. Before the Revolutionary War, 18th century German immigrants brought their native practice with them, notably into Pennsylvania. Settlers, moving westward in their wagon trains, carried the custom into the Western states. But by World War I household worship was vanishing from the domestic scene, except in tradition-loving families of pious heritage.

WORTH, wŭrth, **William Jenkins**, American general: b. Hudson, Columbia County, N.Y., March 1, 1794; d. San Antonio, Texas, May 7, 1849. He received a common school education and was employed in business until the War of 1812 began, when he was commissioned a 1st lieutenant in the Army, serving at Chippawa, Lundy's Lane, and Niagara. Brevetted major, he remained in the Army after the war, although lamed by a wound. From 1820 to 1828 he was commandant of cadets at the United States Military Academy at West Point and in 1838 became colonel of the 8th Infantry.

In 1841–1842 Worth had the chief command in the Seminole War in Florida and was brevetted brigadier general for his services. In the Mexican War (1846–1848) he joined Gen. Zachary Taylor's forces and at the Battle of Monterey (Sept. 21–24, 1846) led a turning movement that entered the city from the south and contributed largely to the victory. He was brevetted major general and received a sword from Congress. In Gen. Winfield Scott's march from Veracruz (1847) he fought with distinction at Cerro Gordo, Churubusco, Chapultepec, and the storming of Mexico City.

Though a skillful and intrepid battle leader, Worth was a poor administrator. He was called to account by Scott for his conduct as occupation governor of Puebla and later gratified his grudge against the general by an intrigue designed to discredit Scott and glorify himself. He was arrested but was freed by President James K. Polk and placed in command of the Department of Texas. Fort Worth, Texas, was named for him,

and a monument to his memory was erected by the City of New York in 1858.

WORTHING, wŭr'thing, municipal borough, England, in Sussex, on the English Channel, 50 miles south-southwest of London. It is a seaside resort and residential town extending inland to the South Downs, which shelter it from the north. It has an exceptionally mild winter climate, and large quantities of grapes and tomatoes are grown for the market. There is a pier with a pavilion, parks and gardens, and an art gallery and museum containing Roman relics. The borough includes large parts of the South Downs, and its northernmost point is marked by Cissbury Ring, the remains of a walled hill city occupied from 300 to 50 B.C., and by numerous flint pits worked as long ago as 2,000 B.C. Pop. (1961) 80,143.

H. GORDON STOKES.

WORTHINGTON, wŭr'thing-tŭn, **Henry Rossiter**, American inventor: b. New York, N.Y., Dec. 17, 1817; d. Tarrytown, Dec. 17, 1880. In 1840 he began a series of experiments with steam for the propulsion of canal boats and devised a small steam pump to be used in the maintenance of the water supply in the engine boiler. In the following year he patented an independent feed pump, the predecessor of the direct-acting steam pump which he patented in 1849. Subsequently, in Savannah, Ga., Worthington built the first direct-acting compound engine to be installed in a waterworks. In 1859 he invented the duplex steam feed pump, still used in the 20th century. He also devised various improvements in steam and hydraulic machinery.

WORTHINGTON, city, Minnesota, seat of Nobles County, on Lake Okabena, 60 miles east of Sioux Falls, S.Dak., and 10 miles north of the Iowa border. It is a trade center in a diversified agricultural area; chief industries include processed poultry, farm sprayers, luggage carriers, ice cream, concrete products, and alfalfa meal. There is a municipal airport. Worthington Junior College, the Worthington Crippled Children's School, and the Nobles County Library are situated here. The community was established as a temperance colony in 1871 and was named Okabena, an Indian word meaning "the nesting place of herons." Government is by mayor and council. Population: 9,977.

W. R. BASSETT

WORTHINGTON, city, Ohio, in Franklin County, on the Olentangy River, adjoining the northern border of the state capital, Columbus. It is mainly a residential community, with some industry in the outskirts. Two miles north of Worthington is the Pontifical College Josephinum. The Ohio Railway Museum and the Worthington Historical Society Museum are points of special interest in the city. Worthington was settled in 1803, by 11 families from Connecticut, whose leader, James Kilbourne, proposed that the village be named in honor of his friend and benefactor, Thomas Worthington, one of Ohio's first United States senators and later governor. The New England background of the founders is visible in the village green that still marks the center of the city and in the churches and other buildings dating from as early as 1804. Government by city manager was adopted in 1957. Population: 14,869.

ELMA A. WHITNEY.

WOTTON, wŏt'ən, Sir Henry, English diplomat, educator, and minor poet: b. Boughton Malherbe, Kent, England, March 30, 1568; d. Eton, December 1639. He attended Winchester School and Oxford University, where he began a lifelong friendship with John Donne. He then spent several years traveling and studying language, art, architecture, and chemistry in France, Germany, Switzerland, and Italy. After returning to England, he became secretary in 1597 to Robert Devereux, 2d earl of Essex, whom he accompanied on two expeditions against the Spanish and on the ill-starred Irish adventure.

Although not a party to Essex's plans, Wotton decided not to return to England when Essex fell, but went first to France and then to Italy. Ferdinand I de' Medici, grand duke of Tuscany, sent him to warn James VI of Scotland of an impending assassination. In gratitude James, when he came to the English throne as James I in 1603, knighted Wotton and named him ambassador to Venice, where he served intermittently during the next 20 years. A witty comment concerning the role of an ambassador brought him temporarily under James' disfavor in 1612; but Wotton apologized, supported the king in Parliament, and eventually returned to ambassadorial duties on the Continent. He devoted himself particularly to the affairs of the queen of Bohemia, King James' daughter Elizabeth.

In 1624 Wotton returned to England for good. His salary was in arrears, and he renewed his entreaties for preferment from the king. He also published *The Elements of Architecture* at this time and received from James the provostship of Eton College. Since Wotton felt the position required him to take religious orders, he did so and spent the rest of his life studying divinity. Feeling death near, he ordered his tombstone inscribed in Latin with the sentence (in translation): "The itch of disputation will prove the scab of the church." Weakened by asthma, he died of a fever.

Wotton wrote many letters and essays. Some of them were gathered together with his poetry, character sketches, and observations on famous people of his acquaintance by his friend Izaak Walton, who prefaced the collection, *Reliquiae Wottonianae* (1651), with his famous *Life of Sir Henry Wotton*. Wotton's reputation as a poet rests upon the slender foundation of some two dozen poems, but the exquisite lyrics *On His Mistress, the Queen of Bohemia, The Character of a Happy Life*, and *A Description of Spring* justify his claim to that honored name.

DONALD B. CLARK
University of Missouri

WOTTON, William, English scholar and clergyman: b. Wrentham, Suffolk, England, Aug. 13, 1666; d. Buxted, Essex, Feb. 13, 1727. He read Latin, Greek, and Hebrew before he was old enough to attend school. After graduating from Catherine Hall, Cambridge, in 1679, he served as librarian to Bishop William Lloyd. Returning to Cambridge, he received the M.A. in 1683 and the B.D. in 1691, at which time he was ordained. As a scholar of wide interests, Wotton wrote several historical and scientific treatises, including *An Examination of Dr. Woodward's Account of the Deluge* (1697); *The History of Rome from the Death of Antoninus Pius to the Death of Severus Alexander* (1701); and *A Discourse Concerning Confusion of Languages at Babel* (1730).

written in 1714. His best-known work was a defense of modern learning, *Reflections upon Ancient and Modern Learning* (1694), which pointed out Sir William Temple's errors in his essay *Of Ancient and Modern Learning* (1690). The *Reflections* called down upon Wotton's head the wrath of Jonathan Swift, which exploded in Swift's now famous *The Battle of the Books* (1704).

DONALD B. CLARK
University of Missouri

WOUK, wŏk, Herman (1915–), American novelist. He was born in New York City on May 27, 1915. He completed an A.B. degree at Columbia University, where he also edited the college humor magazine and wrote varsity shows. He then became a radio scriptwriter, working with Fred Allen from 1936 until June 1941. During World War II he was in the United States Navy and began his first novel during off-duty hours at sea. This work, *Aurora Dawn* (1947), a popular satire of the New York advertising business, was followed by *The City Boy* (1948), a humorous and partly autobiographical story of a Bronx boy, and *The Caine Mutiny* (1951), a Pulitzer Prize novel of events aboard a naval vessel. In *Marjorie Morningstar* (1955) a Jewish girl finds happiness in suburbanite social conformity; in *Youngblood Hawke* (1962) a talented young author is caught up in the intrigue of the publishing world. Other works include plays, motion-picture scripts, and a study of Jewish orthodoxy, *This Is My God* (1959). Later novels include *Don't Stop The Carnival* (1965), *The Winds of War* (1971), *War and Remembrance* (1978), and *Inside, Outside* (1985). Most of Wouk's novels won popular acclaim. They display narrative skill, satire, occasional humor, and a tendency to favor conventional taste.

WILLIAM BRACY, Beaver College

WOUND, wŏond, a traumatic disruption of the continuity of any body tissue. The term usually suggests accidental injury, but surgeons inflict intentional wounds in practically all operations.

Types of Wounds.—Wounds may be classified according to the causative agent, either specifically, such as knife, bullet, or shrapnel wounds, or generally, such as burn or crushing wounds. Surgeons usually classify wounds on the basis of their gross appearance: *incised*, a sharp, clean cut due to a cutting instrument; *lacerated*, a more jagged, irregular wound; *contused*, a wound in which the edges are crushed; *avulsed*, a wound in which some of the tissue is torn away; *penetrating*, a deep wound entering, for example, the chest or the abdomen; *puncture*, a deep wound with a small external opening; and *nonpenetrating*, injury to subcutaneous tissue or viscera without disruption of the body integument. Certain types of wounds and those involving specific tissues may be further subdivided. Fractures (wounds of bone) are classified by descriptive terms such as spiral, comminuted, and impacted. Burns are categorized as first, second, or third degree depending on the depth of tissue injury.

Healing of a Wound.—The healing of a wound is a complex physicochemical process that is only partly understood. Healing may be affected by many factors in the wound and in the body generally, either adversely or beneficially. After a wound has been made, several changes occur simultaneously. Bleeding either stops spontane-

ously or is controlled by bandaging or other means. Dead tissue is removed by the body or by cutting it out (debridement). If the surfaces of the wound are in fairly close contact, the space is filled by blood and tissue juices, which, in addition to other functions, effectively seal the wound. A scaffold consisting of a fine network of protein molecules called fibrin then forms, and into this grow two of the tissues essential for repair. These are connective tissue cells (fibroblasts and histiocytes) and tiny capillary blood vessels. At this stage the repair tissue, called granulation tissue, can be seen in a healing open wound as a red, velvety granular surface. As time passes, several changes take place simultaneously. The fibroblasts produce a fibrous protein called collagen, which gives the wound strength. The histiocytes scavenge cellular debris, foreign bodies, and blood seepage. And the capillaries decrease in number and nearly disappear. The replacement of red capillaries by white collagen explains why a new scar is red at first but then gradually becomes white over the course of several weeks. See also **BLOOD—Clotting; CONNECTIVE TISSUE.**

One measure of the progress of healing is the strength of a wound. A sutured wound loses strength slightly for 2 to 4 days and then rapidly gains strength up to the 7th and 14th day, following which a slow gain in strength is typical. This slow gain then may continue for several weeks.

Factors Affecting Healing. Local factors that affect healing include the type and location of the wound, amount of dead tissue, number and kind of bacteria, presence and type of foreign bodies, blood supply of the wounded part, and the treatment given. A foreign body in a wound may be absorbed by the tissues, which is what happens to catgut used to close a wound; or it may be encapsulated (surrounded by scar tissue), as might happen to a small piece of glass, or extruded, as in the case of a splinter that stays in a wound for some time and then appears on the surface. General body factors that affect healing include age; the presence of certain diseases; and nutrition, especially adequate amounts of protein and vitamin C.

Prevention of Infection. Surgeons take elaborate precautions to prevent infection of the operative wound. Operating rooms are isolated and the air filtered to remove bacteria. Ultraviolet lights may be used to kill the bacteria in the room. Surgeons and nurses wear special clothing, including masks. Gowns, gloves, linens, instruments, and all other materials used in the operation are sterile. The skin in the area of the surgery is prepared with antiseptic agents, and the wound is carefully protected. Antibiotics are sometimes administered.

Accidental wounds are infected when they occur, but the virulence of the infection varies. The wound should be protected with a clean dressing. Water may be used to irrigate the wound, but strong antiseptic agents should not be placed in the wound, as viable cells will be destroyed. A minor cut may be washed with water and dressed with petroleum jelly. A more serious wound should be attended to by a physician.

Durham, North Carolina

WOUNDED KNEE was an engagement between Big Foot's band of Miniconjou Sioux and the 7th U.S. Cavalry at Wounded Knee Creek on the Pine Ridge Reservation, S. Dak. The encounter, which became known as the Wounded Knee massacre, took place on Dec. 29, 1890.

Wounded Knee marked the culmination of the Ghost Dance "war" of 1890-1891, the last major armed conflict between Indians and whites in the United States. When hunger, disease, loss of reservation lands, and broken government promises left no other hope for a satisfactory life, the Sioux had turned to the Ghost Dance religion that had been proclaimed by the Paiute mystic Wovoka.

In November 1890, alarmed by the dance and the growing militancy of the Indians, the Pine Ridge agent called for troops. Gen. Nelson A. Miles assembled an army ultimately numbering more than 5,000 soldiers and attempted to end the troubles without violence. On December 15, however, Chief Sitting Bull was killed at his camp during an attempt to arrest him. On December 28 the 7th Cavalry intercepted Big Foot and his band of some 350 people as they were fleeing south to the Pine Ridge Agency from their village on the Cheyenne River. The federal troops rounded up the Sioux and placed them in a camp on Wounded Knee Creek, 2 miles (32 km) northeast of the agency.

On the morning of December 29 the cavalry, about 500 strong and commanded by Col. James W. Forsyth, attempted to disarm the Sioux. Neither side expected or intended to fight, but the confrontation stirred rising emotions. A medicine man incited the young men to resist. Fighting broke out. The bloody face-to-face encounter and shots from four small cannons posted on nearby hills took many lives. Sioux casualties were counted at 153 dead and 44 wounded, about half of whom were women and children. Those who survived were pursued and butchered by the U.S. troops. Big Foot was slain in the first fire. Losses among the cavalry numbered 25 killed and 39 wounded.

The battle doomed General Miles' effort to avoid bloodshed. Four thousand Indians stampeded and barricaded themselves in a large camp north of Pine Ridge Agency. But in less than three weeks, by a skillful combination of diplomacy and threatened force, Miles ended the violence. He preferred charges against Colonel Forsyth for Forsyth's part in the bloodshed, but a court of inquiry exonerated him.

Then and later many people regarded Wounded Knee as a massacre. To subsequent generations of Indians, it symbolized the injustices and degradations inflicted on them by the U.S. government. In 1973, militants of the American Indian Movement chose the battlefield as a site to dramatize Indian aspirations. About 200 Indians occupied the village of Wounded Knee and alternately traded shots and negotiated with surrounding federal, state, and tribal law-enforcement officers. Two Indians were killed; several persons were wounded, and the village was almost destroyed. The "Second Battle of Wounded Knee" held public attention for days, until the militants surrendered, having succeeded in drawing publicity for Sioux grievances.

ROBERT UTLEY, National Park Service
Author, "The Last Days of the Sioux Nation"

WOUWERMAN, vou'vər-män, **Philips** (1619-1668), Dutch painter of naturalistic genre scenes. Wouwerman (Wouwermans) was born in Haarlem and baptized on May 24, 1619. Trained by his father, Pauwels, and possibly by P. C. Verbeeck and Frans Hals, he was a member of the Haarlem painters' guild in 1640. Many of the more than 1,000 paintings attributed to him may have been done by his brothers Jan and Pieter, with whom he collaborated, or by imitators.

Wouwerman's work shows the influence of Jacob van Ruisdael and Jan Wijnants in its delicate landscape treatment and especially of Pieter van Laer, painter of Roman genre scenes, in its subject matter—chiefly battle scenes, military camps, hunting parties, and innyards. Most of his works include horses, as for example, the *Halt of a Hunting Party* (Dulwich College Picture Gallery, London) and the *Cavalry Camp* (Frick Collection, New York). There are also a few religious and mythological scenes. It was, however, Wouwerman's graceful, tranquil handling of familiar subjects that made his work extremely popular with the merchants of the Netherlands and France. He died in Haarlem on May 19, 1668.

WOVOKA, wō-vō'kə (1856?-1932), was a Paiute Indian mystic. He was born near Walker Lake, Nev., about 1856. His name means "The Cutter." Said to be the son of Tavibo (Tavito) a Paiute religious leader, Wovoka was a medicine man who led a quiet life among the Paviotso, the northern branch of the Paiutes. For a time he worked for a white settler, David Wilson, and was known among the whites as Jack Wilson.

About 1889, Wovoka had a spiritual experience that foretold the coming of a messiah who would restore to the Indians their lost lands and warriors. He prescribed symbolic dances and songs as preparation for the messiah's coming. Known as the Ghost Dance, the ritual swept most of the Indian tribes from the Plains to the Rockies. The Ghost Dance contained elements of Christian theology that Wovoka had learned. Although pacifism was the soul of Wovoka's teachings, apprehension and mutual distrust swept the frontier and led to the Sioux outbreak of 1890, often called the Messiah or Ghost Dance War.

The killing of Chief Sitting Bull and the massacre on Dec. 29, 1890, of more than 150 Indians at Wounded Knee, S. Dak., shattered faith in the cult, and it quickly died down. Wovoka spent his remaining years in obscurity. He died in Schurz, Nev., on Sept. 20, 1932. See also GHOST DANCE; WOUNDED KNEE.

WOZZECK, vō'tsek, is an opera by the Austrian composer Alban Berg, which is regarded as perhaps the most important, impressive, and successful of modern operas. It was composed between 1917 and 1921 and was first performed in its entirety in 1925 in Berlin. It had its American premieres in 1931 at Philadelphia and then in New York City at the Metropolitan Opera.

As the source of his libretto, Berg used a simple abbreviation of the tragedy *Woyzeck* by the early 19th century German dramatist Georg Büchner. *Woyzeck* had been rediscovered by the German expressionist dramatists, and Berg owed much to their exploitation of the sordid and of the subconscious.

Wozzeck, an impoverished soldier subject to hallucinations, is tormented by his sadistic cap-

tain and regimental doctor. His common-law wife Marie leaves him for a brutal drum major, who subsequently beats him up. Wozzeck goes mad, stabs Marie, and drowns himself. A chilling epilogue shows Wozzeck's little son going off to view his mother's corpse. The cruelty and unconcern of man and society is the opera's major theme, catching perfectly a Kafkaesque paranoid vision of life.

In form, *Wozzeck* is similar to Debussy's *Pelléas et Mélisande*. Each of its three acts contains five terse scenes run together by continuous orchestral music. Conventional arias are replaced by declamation over a rich orchestral background. According to Berg, each scene is constructed as a purely musical form, such as sonata, suite, fugue, and invention. In this respect, *Wozzeck* marks an extreme development in the intellectualization of opera. Its unflinching dramatic force derives, however, from Berg's genius for musicodramatic effect, from his convincing musical depiction of abnormality, and from his emphatic emotionalism, notably in Marie's *Lullaby* (Act I, Scene 3) and in the great orchestral interlude between Scenes 4 and 5 in Act III.

Wozzeck has a mistaken and ironic reputation as the popular masterpiece of the 12-tone school of composition, of which Berg was a master. It is mistaken because the opera precedes Berg's adoption of the 12-tone technique. It is ironic because *Wozzeck* is in fact the one widely known mature composition by any composer associated with the school.

WRANGEL, vräng'al, **Count Friedrich Heinrich Ernst von** (1784-1877), Prussian field marshal. He was born in Stettin, Germany (Polish, Szczecin), on April 13, 1784. He fought in the Prussian army against Napoleon. In 1834 he was given command of a division at Münster, where he put down a demonstration by partisans of the archbishops of Cologne against the policy of the king of Prussia.

In 1848 he was commander in chief of the German federal army that drove the Danish troops from Schleswig-Holstein. Under pressure from other great powers, Prussia ended the war with the indecisive armistice of Malmö (August 26). The German people, who had strongly supported the struggle, disapproved of the settlement, and riots occurred in Berlin. Frederick William IV ordered Wrangel to surround Berlin, and on November 10 his troops entered the city. Disorder was suppressed, and the Prussian National Assembly was forbidden to meet again in Berlin.

In 1856, Wrangel was created a field marshal. In 1864, at the age of 80 and almost senile, he was given command of the Austro-Prussian troops that invaded Schleswig. When the aged marshal proved to be a poor strategist, Gen. Helmuth von Moltke was sent to act as his chief of staff and, in fact, assume his command. Wrangel was then replaced by Prince Frederick Charles.

Wrangel was retired with honors and raised to the nobility. Thereafter he served as adviser without command in the Seven Weeks' War in 1866 against Austria. In his later years he interested himself in the reorganization of the army. He died in Berlin on Nov. 1, 1877.

WRANGEL, vräng'əl, **Karl Gustav**, Swedish general: b. Skokloster, on Mälaren, Sweden, Dec. 13, 1613; d. Spieker, Rügen, June 25, 1676. He rose rapidly in the army to the rank of lieutenant colonel and distinguished himself in the Thirty Years' War, in the course of which he was made colonel (1636) and major general (1638). He contributed notably to the Swedish victory at Wolfenbüttel (1641) and, under Lennart Torstenson, took part in the Second Battle of Leipzig (1642).

In 1644, Wrangel was placed in command of the Swedish fleet, defeating the Danes in a battle between the islands of Fehmarn and Lolland (Laaland). Appointed field marshal of the Swedish armies in Germany in 1646, he joined forces with the French in an attempt to break the resistance of Maximilian I of Bavaria and succeeded in forcing upon the elector the Truce of Ulm (1647). With the French, Wrangel defeated the Austrians and Bavarians at Zusmarshausen (1648), but his operations during 1646-1648 have been described as a series of skillful maneuvers rather than battles. Under Charles X Gustavus, he commanded the campaigns in Poland (1655) and Denmark (1657-1659). During the 1660's he was a member of the council of regency. He returned to command the Swedish forces against Brandenburg in 1674-1675, but ill health forced him to relinquish his command before the Battle of Fehrbellin (1675). Wrangel built Skokloster Castle, 10 miles south of Uppsala, which houses one of the finest private collections of weapons in the world, and Wrangel's Palace in Stockholm.

WRANGEL, vrän'gəl, **BARON Pyotr Nikolayevich**, Russian general: b. Novo-Aleksandrovsk, Russia, Aug. 27, 1878; d. Brussels, Belgium, April 25, 1928. He was educated as a mining engineer and spent several years working in Siberia. When the Russian-Japanese War began in 1904, he joined the army and in World War I rose to the command of a cavalry corps. With the outbreak of the Bolshevik Revolution, Wrangel joined the White forces and was put in command of one of the armies in the south by Gen. Anton Denikin. After the shattering of Denikin's 1919 offensive and the retreat of the White armies to the Crimea, Wrangel was given the over-all command in April 1920.

The opening of Polish-Soviet hostilities gave Wrangel's forces new hope, as the bulk of the Red Army was transferred to the Polish front. Although a monarchist, he organized a non-monarchist government in May, attempting to avoid some of the political shortcomings of previous White regimes. He sought with some success the cooperation of non-Russian nationalities, their separatist ambitions notwithstanding, and his government promulgated a land-distribution law aimed at winning the support of the peasants.

Initial military success in the Kuban brought Wrangel's regime de facto recognition by France in August 1920. Soon after, he suffered defeat in the Kuban and turned westward, attempting a junction with the Poles. The Polish-Soviet armistice in October, however, enabled Moscow to concentrate the Red Army against Wrangel. By mid-November 1920 the Perekop Isthmus was

breached and the Crimea cleared of White forces. The French Navy helped to evacuate 147,000 refugees, including 40,000 survivors of Wrangel's army, to Constantinople (Istanbul). Wrangel maintained a staff in Yugoslavia until 1925, attempting to organize the settlement of his soldiers. He spent his remaining years as an engineer in Belgium. *The Memoirs of General Wrangel* was published in English translation in 1929 and, as *Always with Honour*, in 1958.

WRANGEL ISLAND, räng'gəl (Russ. **OSTROV VRANGEL'YA**), island, USSR, in the Russian SFSR, attached for administrative purposes to the Chukchi National Okrug in Khabarovsk Krai. The island, about 100 miles long and up to about 40 miles wide, with an area of 1,740 square miles, is situated in the Arctic Ocean between the Chukchi and East Siberian seas, at latitude 71° N, longitude 180° E. It is separated from northeastern Siberia, to which it is related geographically, by the 83-mile-wide Long (De Long) Strait. Wrangel Island is dominated by two east-west mountain ranges that occupy the center and south of the area and end at the sea in tall headlands. The highest point is Gora Sovetskaya, which reaches over 3,000 feet. The Academy Tundra, a featureless, marshy lowland, occupies the northern third of the island. There are no glaciers on Wrangel, which apparently escaped glaciation during the ice ages. The flora is a varied, preglacial type of considerable botanical interest. The climate is exceptionally bad, with low winter temperatures (February mean, -13° F) and summer temperatures that rarely rise far above freezing point because of the pack ice that is constantly present in the adjacent sea. Fog and low cloud are typical of the summer months. The island is the summer home of large numbers of ducks, geese, and gulls. Land mammals include the Arctic fox and polar bear; walruses and seals are common in the neighboring waters and have been exploited by hunters.

Rumors of land north of the Siberian mainland originated in the 17th and 18th centuries from visits of Chukchis to Wrangel Island. Baron Ferdinand Petrovich von Wrangel (q.v.) unsuccessfully sought the island in the early 1820's. The island was probably sighted for the first time in 1849 by Capt. Henry Kellett of the British Navy after he discovered Herald Island to the east. Thomas Long, an American whaling captain, approached it in 1867; the first landing was made in 1881 by Capt. Calvin L. Hooper, United States Navy, who named it New Columbia. The island remained unoccupied until 1914, when survivors of an expedition led by Vilhjalmur Stefansson lived on it for six months. Stefansson sent an expedition in 1921 to claim the island for Canada, but he received little support. In 1924 the Soviet Union notified other nations that it intended to protect its claim to the island, and in 1926 it created a permanent settlement there, populating it with Chukchis taken from the Russian mainland. The Russian claim was not officially disputed by Britain, Canada, or the United States.

WRANGELL ISLAND, räng'gəl, island, Alaska, in the Alexander Archipelago in the southeast part

of the state. The island is about 30 miles long and up to 14 miles wide and rises to an elevation of over 3,300 feet in the southwest. The chief center is the town of Wrangell (pop. 1,315), on the northern tip of the island, where the Russians first made a settlement in 1811. Later, in 1834, they built Fort St. Dionysius, which was subsequently leased to the Hudson's Bay Company as a trading center. After the sale of Alaska to the United States in 1867, the town became a stop-over for the trip up the Stikine River to the Cassiar goldfields in the Yukon. Fishing is now the principal industry, along with shrimp, crab, and salmon canneries and a sawmill.

IRENE INGLE

WRANGELL MOUNTAINS, mountain range, Alaska, in the southeast, bounded by the Copper River on the West, the Chitina River on the south, and the St. Elias Mountains on the southeast. Of volcanic origin, they extend for about 100 miles from northwest to southeast and are about 70 miles in width. Principal peaks are Mounts Blackburn (16,523 feet), Sanford (16,208 feet), and Wrangell (14,006 feet), an active volcano.

WRANGLER. See CAMBRIDGE UNIVERSITY.

WRASSE, *räs*, the common name for fishes of the family Labridae. They are found in temperate and tropical seas, most frequently inshore in rock pools or around coral reefs, but also in deeper water. The group includes such well-known fishes as the tautog, cunner, hogfish, bluehead, California sheepshead, and about 100 others.

Wrasses are long and solid bodied. Their strong jaw teeth are not fused into a beak as in the parrot fishes. The pharyngeal (throat) teeth are blunt and strong and are used to crush harder food. The scales are large and cycloid. Adult sizes range from 3 inches to several feet and a weight of over 40 pounds. In the United States, two well-known northern wrasses—the tautog and the cunner—are dull in color, but farther south on both coasts there are brilliantly colored representatives of the family, such as the small, bright blue and green bluehead, the red hogfish, and the rose and black California sheepshead. In some genera, the male and female are unlike in color; in some also, the young differ markedly from the adults.

Wrasses feed on seaweed, small fishes, mollusks, and crustaceans. The wrasses themselves are not food fishes, although a few of them are edible. Most of them are not popular with anglers, but a few, such as the strong, fast hogfish, put up a good fight when hooked.

WREATHS. See CROWNS AND CORONETS—*Pre-Christian Era*; HERALDRY.

WRECKS AND WRECKAGE, *rëks*, *rëk'ij*, in maritime history and law. In its broadest sense in this context, *wreck* means anything without an apparent owner that is floating upon, sunk in, or cast on shore by the sea. In maritime legal usage, a wreck is the remains of a ship stranded and abandoned on shore, while *wreckage* is any goods or property cast ashore and a *derelict* is an abandoned ship at sea. *Wrecker* was a common

term in the days of sail but is almost obsolete today. It signified one who made a living from plundering wrecks or disposing of wreckage. Such people were at times accused of luring ships ashore with false lights but such folklore and sailors' tales are not supported by documentary records. In fact, wreckers, though primarily interested in profit from wreckage, often saved the lives of shipwrecked persons, and from their activities came the lifesaving services of both Britain and the United States.

With the advent of steam power and steel construction, ships could more easily remain off a lee shore, and those stranded could often be saved by assistance of powerful tugs fitted for that purpose. Predatory wrecking off United States coasts is now prevented by law enforced by the Coast Guard, which also took over (1915) the Lifesaving Service. Legitimate wrecking is now called *salvage*. Saving of life at sea is required by law, but salvage is voluntary and a private enterprise, stimulated by maritime law assuring a salvor financial reward for his effort.

A famous wreck of modern times was the luxury cruise liner *Morro Castle* which burned off Asbury Park, N.J., on Sept. 8, 1934, and drifted ashore. The predatory instinct toward wrecks again manifested itself in the robbing of the bodies of her dead. The *Morro Castle* disaster brought about the Merchant Marine Act of 1936, which is the law of the sea for United States ships. A comparable law in Britain was enacted in 1894.

JOHN D. HAYES,

Rear Admiral, United States Navy (Retired)

WREN, *rën*, Sir Christopher, English architect: b. East Knoyle, Wiltshire, England, Oct. 20, 1632; d. London, Feb. 25, 1723. He turned from a brilliant scientific career to become the most important English architect of the 17th century and, in the opinion of many, the greatest. His early life was marked by precocity in mathematics and the natural sciences and an interest in mechanical contrivance. He went to Wadham College, Oxford, at the age of 17 and, after graduating M.A. in 1653, spent three years in study and research in astronomy as a fellow at All Souls College. In 1657 he became professor of astronomy at Gresham College, London, returning to Oxford in 1661 as Savilian professor of astronomy. He resigned this post in 1673 but retained his scientific interests and his fellowship of the Royal Society of which he had been, in 1660, a founder.

Career and Works. In 1663 Wren made his first architectural designs—for the chapel of Pembroke College, Cambridge, and the Sheldonian Theatre at Oxford. He was also appointed that year to advise on the repair of the medieval St. Paul's Cathedral. He was a self-taught architect, and the extent of his nine-month visit to France in 1665–1666 suggests that he had by then chosen an architectural career. His choice was sealed by the Great Fire of 1666, which damaged St. Paul's irreparably and destroyed three quarters of the City of London. Although his plan for rebuilding the City, produced with great speed, was not accepted, he was appointed a commissioner for the rebuilding and, in 1669, surveyor general of works. The latter post put him in charge of all royal and government building in Great Britain.

© JOHN MOSS/BLACK STAR

Sir Christopher Wren's design for the Sheldonian Theatre at Oxford was influenced by his study of 16th century Italian architecture.

Wren made or authorized designs for rebuilding 52 London churches, notably St. Bride, Fleet Street; St. Stephen, Walbrook; St. Mary-le-Bow; and St. Anne and St. Agnes. Outside the city he designed the churches of St. Clement Danes and St. James, Piccadilly. In this, the first big church-building program since the Reformation, he set the types for Protestant churches for the ensuing two centuries. He also designed, with Robert Hooke, the monument on Fish Street Hill, commemorating the Great Fire. His greatest work, the new St. Paul's Cathedral, was built in 1675–1710; building was preceded by several years of designing, and the accepted designs received continual modification, the dome and western towers being conceived after 1700.

Wren was knighted in 1673 and was president of the Royal Society in 1681–1683. He took little interest in politics but was twice a member of Parliament—in 1685–1687 for Plympton and in 1701–1702 for Weymouth—his main concern being the furtherance of St. Paul's. His long control of the Office of Works enabled him to assemble a talented team of designers, craftsmen, and administrators, but by the accession of George I in 1714 changes in taste had brought criticisms of his virtual monopoly. In that year political and artistic intrigue secured his replacement by a board of commissioners, though he retained the title of surveyor general until 1718.

No country houses can be attributed to Wren with certainty, but as the king's chief architect he designed the palaces of Winchester for Charles II, and Kensington and the rebuilding of Hampton Court for William III. Only half of Hampton Court was carried out, according to a reduced scheme. In the royal hospitals of Chelsea (for soldiers, begun 1682) and Greenwich (for seamen, begun 1696), both modeled on Louis XIV's Invalides, he was able to handle masses on a large scale. These buildings give some suggestion of the effect of his abortive scheme of 1698 for a great palace in Whitehall, London, for which designs are extant. Greenwich is partly the work of his assistants, but he was responsible for the hall and the domes and colonnades, as well as the plan. The hall (painted by Sir James Thornhill) is the finest surviving baroque inte-

rior in England, and Greenwich and Hampton Court are among the major monuments of the baroque style.

Style. Although he never visited Italy, Wren's earliest work was largely inspired by Italian Renaissance architecture; the culmination of this phase was the library of Trinity College, Cambridge (1676–1685). An increase in scale during the 1680's was accompanied by a greater reliance on French and Italian art of a period nearer his own time, and research since 1950 has confirmed that these stylistic changes were his own rather than due to his pupils and assistants. Wren's lifespan saw great changes, from the establishment of the pure Renaissance style introduced by Inigo Jones to its development toward a freer, more dramatic baroque and, in the last decade of his life, the rise of the simpler and deliberately limited architecture of Palladianism.

St. Paul's Cathedral, the central work in Wren's career and the monument in which he is buried, reveals all his many qualities. His mathematician's feeling for shape (which he recorded) informs the miraculously simple shape of the dome, while his appreciation of baroque plasticity is evident in the western towers; their contrast with the dome, achieved after many experimental designs, is the work of a man fully conscious of the visual impact of architecture. His structural ingenuity is seen in the complex buttressing system of the dome and the use of a brickwork cone to raise the lantern and outer dome to a telling height above the interior. Of his wide range and assured use of decorative detail and the high standard of craftsmanship he encouraged, every part of the building is evidence.

WREN, a small songbird of the family Troglodytidae. The family is well defined and homogeneous, consisting of about 60 species restricted to the New World except for a single species that inhabits Eurasia as well as North America. This species, *Troglodytes troglodytes*, called simply "wren" in England, is known as the winter wren in North America. It is the subject of a very rich folklore in Europe.

AUSTING AND KOEHLER FROM THE NATIONAL AUDUBON SOCIETY

A house wren perches at the entrance to its nesting box. House wrens range from southern Canada to Argentina.

Wrens are plain, solitary little birds that sing loudly and can scarcely be mistaken for any other bird. They vary in size from 4 to 9 inches (10–23 cm), most of them averaging less than 6 inches (15 cm), and are brown or grayish, more or less speckled with white. The bill is slender, usually fairly long and slightly decurved, the legs are long, and the wings are very short and rounded. The tail is typically short and stubby and is carried cocked upward at a sharp angle. The song, usually liquid and very musical, carries far and is given with great abandon, the whole creature quivering with the effort. In some wrens, however, such as the cactus wren (*Campylorhynchus brunneicapillus*), which inhabits the deserts or very arid regions of the United States and Mexico, the song is a jumble of harsh and grating notes.

Wrens are usually found on or near the ground, feeding chiefly on insects and spiders. They build globular nests with a side entrance. The building is done by the male, which makes several nests before the female selects one, usually better constructed and better concealed than the others, in which to raise the family. This habit is not understood, but the "dummy" nests are used for sleeping, and it is believed that they may also delude predators. The familiar house wren (*T. aedon*) of the United States, which frequents the vicinity of human dwellings, seems, however, to prefer a hole about a building or any suitable nesting boxes that are offered.

CHARLES VAURIE

Former Curator, Department of Ornithology
The American Museum of Natural History

WRESTLING, res'ling, a sport in which two opponents grapple for supremacy according to prescribed rules. Originating in antiquity, wrestling is the oldest and most basic form of recreational combat. Modern amateur wrestling is essentially a refinement of ancient techniques.

Styles and Classes. Modern Olympic and world amateur championships are conducted in two styles: freestyle and Greco-Roman. There are 10 weight classes, ranging from 48 kilograms (105.5 pounds) to 100 kg (220 lbs), plus heavyweight. In 1985 an upper limit was set for the heavyweight class: no contestant may weigh more than 130 kg (286 lbs). All international competition is governed by the Fédération Internationale de Lutte, or the International Amateur Wrestling Federation (FILA).

Freestyle. Of the international wrestling styles, freestyle is the most popular in the United States, because it closely resembles the folkstyle practiced in scholastic and collegiate programs. In freestyle, a wrestler may attack his opponent's legs, as with single-leg or double-leg tackles, or he may apply other holds below the waist, such as the fireman's carry or the crotch lift. He also may use his own legs to attack, as with trips and some types of scissors holds. The defensive wrestler may also use his legs to counterattack or to block certain lifts.

Points are scored in freestyle for takedowns (1), reversals (1), and near falls (2). A near fall, or tilt, is scored by turning an opponent's back to the mat at an angle of less than 90 degrees, or by touching both his shoulders to the mat for an instant. If both shoulders are held to the mat for one-half second, it is ruled a fall and the match is over. If, from a standing position, a wrestler throws his opponent directly into a near fall, the action is worth 3 points. Such a maneuver performed with a spectacular high-arching throw is awarded 4 points.

Greco-Roman. The rules for Greco-Roman wrestling are identical to those for freestyle, with one exception: the legs may not be used in attack or defense. That limitation, however, occasions significant differences in philosophy and style. Much of the scoring results from spectacular arching throws, inasmuch as a defensive wrestler being lifted may resist only by shifting his weight and balance and not by blocking with his legs or by grasping his opponent's legs.

Sombo. A third international style, *sombo* has not yet been accepted as an Olympic sport, although world championships have been conducted. The name *sombo* is derived from a Russian acronym standing for "self-defense without weapons." A blend of wrestling and judo, it draws rules and participants from both. *Sombo* may come to be recognized as a separate sport.

The Wrestling Match—Area, Equipment, and Officials. Today's wrestling mat is 4 to 6 centimeters (about 2 inches) thick and made of a foam-core plastic with a smooth bonded cover. The center wrestling area is 7 meters (23 feet) in diameter and is surrounded by a 1-meter band called the "passivity zone."

Each wrestler is attired in a one-piece uniform called a singlet, one wearing red and the other blue, and ankle-high shoes without heels. Light kneepads are permitted, but additions such as headgear or T-shirts are not.

Three officials—a referee, a judge, and a mat chairman—direct the bouts. At least two officials must agree on any decision.

The Bout. Each bout consists of two 3-minute periods, a total of 6 minutes of actual competition. During the one-minute interval between periods, each wrestler may be assisted by a coach and masseur. Each period starts with the wrestlers on their feet facing each other 1 meter apart. If the wrestlers step into the "passivity zone" with no action in progress, they are returned to the center for a fresh start.

The 6-minute bout can be cut short by a fall, by one wrestler opening a lead of 12 or more points over his opponent, or by disqualification for passivity, illegal holds, or misconduct.

A fall occurs when a wrestler's shoulders are pinned to the mat for one-half second. The winner of a full 6-minute bout is determined by points awarded for successful execution of specific maneuvers, such as takedowns (bringing the opponent to the mat from a standing position), reversals (exchanges of control), near falls (turning the opponent's shoulders toward the mat at an angle of less than 90 degrees), and a variety of throws to the mat.

Once a wrestler has taken his opponent to the mat, he is given the opportunity to continue in "par terre" position (on the ground) and to attempt to turn his opponent's shoulders into a "danger" position—past 90 degrees. If the officials believe that he will not succeed quickly, both wrestlers are returned to the standing position. No points are scored merely for controlling an opponent.

The rules strictly forbid tactics intended to injure the opponent, such as hair-pulling, scratching, grabbing the throat, twisting the fingers or any joints, or driving a knee or elbow into the opponent's back or abdomen.

Total Wrestling. Through the efforts of FILA President Milan Ercegan of Yugoslavia, the concept of "total wrestling" has become the guideline for international competition. The bout was shortened from 9 to 6 minutes, but constant aggressive activity is required or the passive wrestler is penalized and perhaps disqualified. The element of "risk" is the keynote of the new philosophy: the wrestler must take risks to score, particularly if his opponent is ahead on points.

Wrestling in the United States. The rules for collegiate and scholastic wrestling in the United States vary sharply from those of international freestyle, placing emphasis on control of the opponent rather than on physical dominance. A fall must be held for one second (collegiate) or two seconds (scholastic). Requirements for near-fall points are much more demanding. Points are awarded for takedowns and reversals, but spectacular throws are prohibited. Escaping from an opponent is a scoring maneuver, and merely controlling him can earn a point for time advantage. As in international wrestling, the rules of the National Collegiate Athletic Association and the National Federation of State High School Associations strictly forbid brutality and place special emphasis on the physical safety of the wrestlers.

The national governing body and international delegate for the sport is USA Wrestling, which conducts national championships each year in both freestyle and Greco-Roman. As part of its responsibilities for promotion of the sport, USA Wrestling conducts an extensive series of clinics in coaching, officiating, and sports medicine, and produces books, films, and videotapes. As many as 70 regional and national tournaments are con-

ducted annually for various age groups, starting as young as 9.

All such competition is under international rules, subject to modifications adopted for the health and safety of young wrestlers. Some of these events determine the lineups of United States teams competing against the national teams of other countries.

The offices of USA Wrestling are housed in the National Wrestling Hall of Fame and Museum in Stillwater, Oklahoma.

Famous Amateur Wrestlers. Because of the intense popularity of collegiate wrestling, most of the 20th century heroes of the sport are recognized largely for their undergraduate achievements. Dan Gable, for example, is better known for his 100 victories as a collegiate wrestler at Iowa State University and his 100-plus wins as coach at the University of Iowa than he is for his Olympic gold medal in 1972 or his role as Olympic freestyle coach in 1984.

Other "giants" of the sport in the United States include Robin Reed of Oregon State, a 1924 Olympic gold medalist at 134 pounds, who never lost a match to any opponent of any size; skilled technicians such as Stanley Henson of Oklahoma State in the late 1930's and Bill Kolhof of Northern Iowa in the 1940's; Danny Hodge of Oklahoma, an athlete of incredible strength who pinned almost all of his opponents, in the 1950's; and Henry Wittenberg, a New York policeman, who won more than 300 matches in a row and collected gold and silver medals in the 1948 and 1952 Olympics.

The "first family" of American wrestling is that of Rex Peery, who won three national collegiate championships at Oklahoma State (1933-1935) and then coached his sons Hugh and Ed to three titles each at the University of Pittsburgh in the 1950's.

Professional Wrestling. In the early decades of the 20th century, professional wrestling was popular in the United States, reaching its peak in the 1920's and 1930's. It has since degenerated into a prearranged display of rough-and-tumble acting, with designated "heroes" and "villains," and no longer is considered a competitive sport.

Folklore Styles. More than 160 traditional or "folklore" variations of wrestling are recognized by the FILA. In the Soviet Union, championships and exhibitions of folklore wrestling are held, such as *tchidaoba* from Georgia, *kokh* from Armenia, *gulech* from Azerbaidzhan, *kurach* from Uzbek, and *kurek* from Kazakhstan. In Britain, styles were developed that took the names of their districts of origin: Cumberland, Westmoreland, Cornwall, and Lancashire. In the Cumberland style, if the starting hold is lost or if any part of the body except the feet touches the ground, the contestant loses. In the Cornwall and Devon style, the match begins from the upright position, and ground wrestling is prohibited. In Germany, wrestling holds and maneuvers were entirely on the ground.

In Switzerland the popular style known as *schwingen* features special pants and a strong belt that the wrestlers grip at the start of a match. In *glima*, popular in Iceland, the wrestlers are equipped with belts for grasping. Similar styles prevail in Syria and some parts of the Soviet Union.

Wrestling has been popular in the Orient for at least 2,000 years. In the Japanese *sumo*, perhaps

BASIC WRESTLING HOLDS

Each period of a match starts with the wrestlers in a neutral, or on-guard, position with hands held palms-down in front of hips.

In the *tie-up*, wrestlers vie from the standing position to secure a grip for advantage in forcing the opponent to the mat.

A legal *headlock*, which must include an arm as well as the head, could result in an immediate fall.

The *hiplock*, a standard hold for advantage, may result in one of several forcing maneuvers.

With the hiplock secured, a wrestler may follow with the *hip throw* to take down his opponent.

In the *gut wrench*, a basic scoring maneuver, the opponent is held across the abdomen with head down.

With the *souplesse*, a belly-to-belly maneuver, a wrestler may turn his opponent sideways or on the back.

The *back-arch throw* (or *salto*), a belly-to-back maneuver, often results in an immediate fall.

the best known and most stylized of folklore wrestling, the winner is determined when the opponent is thrown to the ground or forced outside the boundaries of the mat. *Sumo* has no weight classes, and most contestants tip the scale at 300 to 400 pounds (136–181 kg).

History. Carvings and drawings 15,000 to 20,000 years old, found in caves in France, illustrate wrestlers in hold and leverage positions. Sumerian wrestlers were cast in bold relief on stone slabs at least 5,000 years ago. A bronze statuette of wrestlers, dated 2600 B.C., was unearthed in the ruins of Khajafi, near Baghdad.

In Egypt, paintings of wrestlers dating from about 2500 B.C. were found in tombs of kings and officials. In the tomb of the vizier Ptah-hotep six different wrestling holds are shown. The hundreds of drawings in the temple-tombs of Beni Hasan demonstrate that most holds in use today were performed in ancient Egypt. The maneuvers depicted are more closely related to the present-day sport than are those of such modern forms as *sumo*, *kohk*, and *glima*, for example.

The Greek poet Homer described wrestling matches, and the sport became the final and decisive event of the pentathlon at the public games. The poet Pindar describes how the gods Zeus and Cronus wrestled for possession of the universe along the river Alpheus at Olympia. Zeus was victorious, and the first Olympic festival was held in 776 B.C. to commemorate his triumph. In the 18th Olympiad, in 708 B.C., wrestling was introduced as a major sport. The philosopher Plato as a young man won many prizes for wrestling. His real name was Aristocles, but because of his success he was given the name Plato, meaning "broad shoulders."

After the conquest of the Greek Empire by the Romans, the sport degenerated into violent gladiatorial contests, in which the loser often did not survive. As the Roman Empire expanded, the contests spread across Europe. The "catch-as-catch-can" style, the forerunner of modern freestyle, developed: no holds were barred on any part of the combatants or their garments. In Europe during the Middle Ages, wrestling was considered a knightly skill. In 1520 at the Field of the Cloth of Gold, Henry VIII of England and Francis I of France watched wrestling matches between their countrymen. Henry challenged Francis and reportedly was thrown by him.

During the Napoleonic era, in the early 19th century, the French developed a style identified today as Greco-Roman: holds on or with the legs, and tripping, were prohibited.

In both North and South America, Indians engaged in wrestling bouts long before Columbus set foot in the New World. Among American presidents, George Washington, Abraham Lincoln, and William Howard Taft were skilled wrestlers.

WREXHAM, rek'səm, a town and market center in Wales, in Clwyd county, 10 miles (16 km) southwest of Chester, England. Its industries include coal mining, leatherworking and tanning, brewing, and the production of chemicals, synthetic fibers, and plastics.

St. Giles Church, whose present structure dates from the 15th and 16th centuries, is renowned for its Gothic tower, one of the traditional "seven wonders of Wales." In the churchyard is the grave of Elihu Yale, the early benefactor of the American university that bears his name. Population:(1981) 40,272.

WRIGHT, Frances (1795–1852), British-American social critic, who was active in the causes of women's rights, education, and reform in early 19th century America. Frances (Fanny) Wright was born in Dundee, Scotland, on Sept. 6, 1795. Her parents died when she was two years old, and she became heir to a substantial fortune. She first visited the United States in 1818–1820, and in 1821 published an enthusiastic book, *Views of Society and Manners in America*. Contradicting the disparaging accounts of most foreign tourists, the book interested European intellectuals. Wright formed a close friendship with the Marquis de Lafayette. She and her sister Camilla joined him in his triumphal tour of the United States in 1824–1825.

Fanny Wright thereafter determined to work at solving the problem of black slavery in the United States. She bought a few slaves and 2,000 acres (80 hectares) of woodland, which she called Nashoba, in western Tennessee. She was not an abolitionist, but she hoped to demonstrate that slaves by their labor could buy their freedom and finance their colonization outside the United States while their children were being schooled for freedom. Her *Plan for the Gradual Abolition of Slavery* (1825) won the approval of Thomas Jefferson and James Madison, but before it could be put into practice, Fanny Wright met Robert Owen and his son Robert Dale Owen. Impressed by their socialist utopia in New Harmony, Ind., she resolved to make Nashoba a cooperative community. One of her radical recruits published a report that Nashoba advocated free love and racial interbreeding. The scandal had little basis, but it killed Nashoba.

Fanny Wright eventually settled her slaves in Haiti. Meanwhile, she had become America's first woman lecturer. Tall and strikingly handsome, with a voice of singular power, she denounced the influence of the church in politics and demanded rights for women and workingmen. With Robert Dale Owen she edited the *Free Enquirer* in New York City (1829–1830), which opposed imprisonment for debt and proposed free public education and birth control. For a woman to make public her views on birth control was considered unforgivable. Although mobs threatened her and the newspapers attacked her, the "Fanny Wrighters" polled 6,000 votes in the New York election of 1829.

In 1831, Fanny Wright married William Phikepal D'Arusmont. Her return to lecturing in 1835 led to the breakup of her marriage. She died in Cincinnati, Ohio, on Dec. 13, 1852.

Unity Temple (above), in Oak Park, Ill., is an outstanding example of the early work of Frank Lloyd Wright. The architect designed his winter home, Taliesin West (right), to conform with the rugged beauty of its Arizona setting.

PHOTOS BY HEDRICH BLESSING

WRIGHT, Frank Lloyd (1867–1959), American architect, considered by some to be the greatest American architect of all time and one of the world's greatest. During his 70-year professional career, he made important contributions to the modern movement in architecture. A great designer, he was also a dedicated innovator, theoretician, and teacher. And he left his mark on his times in a way that is unmatched by any of his architect contemporaries.

Life. Wright was born in Richland Center, Wis., on June 8, 1867. His father deserted the family when Wright was 16. His mother was a strong and willful woman, who had decided before he was born that he would become an architect. When he was a young child his mother gave him paper, blocks, and other simple materials, which he would arrange, with her help, into shapes resembling rudimentary furniture and buildings. He later maintained that this training deeply affected his architecture.

At 18, Wright enrolled in the engineering school of the University of Wisconsin but dropped out after less than two years. He went to work for James Lyman Silsbee, a Chicago architect, but only stayed a few months. He then found a job with Adler and Sullivan in Chi-

cago and thus came under the influence of Louis Henri Sullivan, now acknowledged as the first modern American architect. Sullivan summed up his architectural philosophy as "form follows function," by which he meant that the design of buildings should derive from their uses. This was a radical idea at the time, but one that Wright readily accepted from the man whom he would ever after call "Master." Wright stayed there about five years first as a draftsman and later as a designer. He worked on several of the great Sullivan buildings and designed the Charnley House (1891), in Chicago, for the firm. In 1889, Wright designed his own house in Oak Park, Ill. His earliest commissions were for houses, which he moonlighted while working for Adler and Sullivan.

In 1893 he left the firm to start his own practice, first in Chicago and later in Oak Park. After leaving his family for another woman, Wright went to Europe for a year. Upon his return he went to Spring Green, Wis., where he had inherited his family's farm. There, in 1911, he built his famous house, Taliesin. In 1915, Wright designed the Imperial Hotel in Tokyo and during its construction spent most of his time in Japan until 1922.

After a series of personal and professional misfortunes, Wright was declared bankrupt in 1928 and all of his possessions were sold. During the Great Depression, Wright designed a number of buildings, but none were constructed. He supported himself mostly by lecturing and writing. In 1932 he established the Taliesin Fellowship, a combination of architectural schooling and apprenticeship. Students who admired Wright's work went to Taliesin to learn from him; many of them never escaped his influence during their later professional years.

During the later 1930's, Wright received a number of commissions for buildings of various types. He also began to receive considerable recognition, in Europe rather than in his native country, for his architectural designs. In 1937, Wright began to plan Taliesin West, in Scottsdale, Ariz., which became his winter home and studio. Architectural commissions were again scarce during World War II. Wright designed a few buildings, but almost none were constructed. After the war, commissions came in rapidly. His talents renewed, he produced a number of fine works. By the end of his career, he had designed more than 400 buildings. Much honored and admired for his accomplishments, he died in Phoenix, Ariz., on April 9, 1959.

Work. Wright lived so long and was so creative that it is useful to divide his professional life into three phases: an early period (1893–1910), a mature period (1910–1945), and a later period (1945–1959).

Early Period. During the early years of his practice, Wright designed mostly houses and apartment buildings in Chicago and Oak Park, Ill., and nearby towns. These buildings were not really indicative of the path on which his talents would take him later. Although well designed and detailed, they were very much like buildings by many academic architects of the time. However, his Willits House (1902) in Highland Park, Ill., was a giant step forward. It contains virtually the first suggestion of his later designs—open interiors and long, low exteriors, with hipped roofs and wide overhangs—in what came to be known as the "Prairie Style." Notable examples in this style were the Heurtley House (1902), Oak Park, and the Martin House (1904), Buffalo, N.Y.

Then Wright designed what many consider his first masterpiece, the Larkin Company Administration Building (1904), in Buffalo. It was noted not only for its architectural form and detailing, but for its great interior atrium, often used in buildings today but an oddity then, and for its early use of plate glass and air conditioning. The building was demolished in 1950.

Other masterpieces soon followed, including Unity Temple (1907) in Oak Park and the Robie House (1909) in Chicago, usually considered Wright's finest Prairie Style house. Another structure of importance is the Coonley House (1909), River Forest, Ill.

Mature Period. Wright started this period with the design of his own house, Taliesin (1911), in Spring Green. Other fine houses followed. He then designed a very large project, the Midway Gardens (1914), a great decorative indoor-outdoor amusement center in Chicago. It was demolished in 1929. Taliesin burned and was rebuilt in 1915. For more than six years, beginning in 1916, the Imperial Hotel (1922), in To-

kio, Japan, absorbed much of his energies. After surviving earthquakes and other problems, the building was demolished in 1968.

Wright also designed several significant houses in the United States, some of them in experimental custom-designed concrete block, a material usually considered then and now as among the most mundane. Notable examples include the Barnsdall House (1920), in Los Angeles; the Millard House (1923), in Pasadena, Calif.; and the Freeman House and Ennis House, both in Los Angeles, completed in 1924.

Taliesin again burned in 1925 and Wright rebuilt it again, in considerably altered form. During the Depression, Wright had little work. In 1937 he designed "Fallingwater," the Edgar Kaufmann House, near Bear Run, Pa. With its daring structure cantilevered over a waterfall, this house has been called the very finest of Wright's many designs.

During this period Wright designed a new style of house, which he called the "Usonian," that was as radical as his earlier Prairie houses had been. These new houses were usually relatively small and compact and utilized a modular system, far ahead of its time. They had other modern features, such as concrete slab floors incorporating pipes for hot-water heating and wood sandwich-panel walls, assembled at the site and then placed into position in the houses. Over the years, he designed a number of these houses, each incorporating new improvements.

Then came two masterpieces, Taliesin West, still being remodeled at the time of his death, and the Johnson Wax Company Administration Building (1939) in Racine, Wis. In 1938, Wright designed the master plan, his first, for Florida Southern College, Lakeland, Fla. The first building was completed that same year and nine others followed, the last completed in 1954. Wright designed a number of houses during the late 1930's and a few during the World War II years. In 1943 he designed the outstanding Guggenheim Museum in New York City, but more than 15 years passed before it was built.

Later Period. After World War II, Wright, at 78, entered an era of great activity. One commission produced another masterpiece, the Johnson Wax Company Laboratory Tower (1949). Other notable buildings during these years include the Unitarian Church (1947), Madison, Wis., and the Price Company Tower (1953), his first and only high-rise office building, in Bartlesville, Okla. In 1956, at last, construction began on his Guggenheim Museum; also under construction were his Beth Shalom Synagogue, Elkins Park, Pa., and the Kalita Humphreys Theater, Dallas. All were completed in 1959, the year Wright died.

A number of Wright-designed houses and other buildings were constructed following his death, with necessary architectural services performed by his successors, Taliesin Associated Architects. The last major building was the Marin County Civic Center (1962), in San Rafael, Calif.

See Index entry *Wright, Frank Lloyd* for other illustrations of his work.

WRIGHT, Harold Bell (1872–1944), American novelist. He was born in Rome, N.Y., on May 4, 1872. Successively a house painter, a landscape painter, and a pastor, he turned to writing fiction while serving a Pittsburg, Kans., church. He published his first novel, *That Printer of Udell's*, in 1903. Of his 18 other novels, the most popular were *The Shepherd of the Hills* (1907), *The Calling of Dan Matthews* (1909), and *The Winning of Barbara Worth* (1911). Wright died in La Jolla, Calif., on May 24, 1944.

His stories, which are estimated to have sold over 10 million copies, chiefly concern love and adventure in the Southwest. They are moralistic and sentimental, but his treatment of local color and background is excellent.

WRIGHT, Henry (1878–1936), American landscape architect and city planner. He was born in Lawrence, Kans., on July 2, 1878. After studying architecture at the University of Pennsylvania, he assisted in the landscaping for the Louisiana Purchase Exposition in St. Louis in 1904 and designed parks and boulevards in many Midwestern cities. Among the numerous community plans on which he worked were Sunnyside Gardens in Queens (New York City), the renowned Radburn project in the borough of Fair Lawn, N.J., and Chatham Village, in Pittsburgh, Pa. As the planning director of the New York State Housing and Regional Planning Commission, he laid the groundwork for a classic report, *A Plan for the State of New York* (1926).

The most important of his many innovations was the superblock with an internal park at its core. Wright pioneered in housing cost accountability and was a major force in the advancement of city planning education. He died in Newton, N.J., on July 9, 1936.

WRIGHT, James Arlington (1927–1980), American poet, who won the Pulitzer Prize in 1972 for *Collected Poems*. He was born in Martins Ferry, Ohio, on Dec. 13, 1927. After four years in the U.S. Army, he studied under John Crowe Ransom at Kenyon College and Theodore Roethke at the University of Washington (Ph.D., 1959). He later taught at the University of Minnesota, Macalester College, and Hunter College. He died in the Bronx, N.Y., on March 25, 1980.

Wright's first books of poetry were *The Green Wall* (1957) and *Saint Judas* (1959), both influenced by Edwin Arlington Robinson. He then became associated with the experimental poets Robert Bly and William Duffy. He made verse translations of such poets as Pablo Neruda, Georg Trakl, and César Vallejo. Wright's later volumes include *The Branch That Will Not Break* (1963), *Shall We Gather at the River* (1968), *Two Citizens* (1973), *The Blossoming Pear Tree* (1977), and *The Journey* (1982).

WRIGHT, James Claude, Jr. (1922–), American political leader, who served as Speaker of the U.S. House of Representatives. Wright was born in Fort Worth, Texas, on Dec. 22, 1922. After studying at Weatherford College and the University of Texas, he served in the Army Air Force during World War II. Entering politics as a Democrat, Wright was elected in 1946 to the Texas House of Representatives, but his support of civil-rights bills cost him reelection.

Wright won a seat in the U.S. House from the Fort Worth area in 1954 and was regularly reelec-

ted every two years thereafter, though he failed in Senate bids in 1961 and 1966. Wright was a liberal on economic issues. Although he opposed the Civil Rights Act of 1964, he supported most subsequent civil-rights bills. He backed U.S. policy in Vietnam.

A skilled and tenacious legislator, Wright was elected Democratic majority leader of the House in 1976. He succeeded Thomas P. O'Neill, Jr., as Speaker in 1986. He was considered a very effective Speaker and compiled an impressive legislative record. But in May 1988 complaints were filed with the House ethics committee charging that Wright had attempted to circumvent House rules on outside earnings by arranging for unusually high royalties on a book he had written and by improperly accepting gifts from a Fort Worth developer. Wright denied that he had knowingly broken House rules. After a lengthy investigation, in the course of which his political position was badly eroded, Wright resigned from the speakership in May 1989 and from the House itself in June of that year.

WRIGHT, Orville. See WRIGHT, WILBUR AND ORVILLE.

WRIGHT, Richard Nathaniel (1908–1960), American writer. He was born near Natchez, Miss., on Sept. 4, 1908. During his childhood he suffered from poverty and parental neglect, and at the age of 15 he began to shift for himself in Memphis, Tenn. Here he developed an interest in reading that awakened a desire to become a writer. After roaming about the country for a few years, he went to Chicago in 1934, began to identify himself with Communist activities, and found employment with the WPA Federal Writers' Project, moving to New York in 1937. After World War II he lived in Paris, France, where he died on Nov. 28, 1960.

Wright's first book, *Uncle Tom's Children: Four Novellas* (1938; reissued in 1940 with a fifth story), depicts melodramatic, highly emotional scenes of violence and injustice arising from conflicts between whites and blacks in the South. A Guggenheim fellowship enabled him to complete a full-length novel, *Native Son* (1940), which was universally acclaimed. It is a tense and moving study of a young Chicago black convicted of murder, sympathetically portrayed as a victim of social and economic injustice. In *Black Boy* (1945), a distinguished autobiographical novel about his own unhappy childhood and teenage years in the South, Wright reached the height of his literary powers.

Later novels and short stories were less successful. *The Outsider* (1953) draws upon his experiences as a Communist before he denounced the party and discontinued his membership in 1944. *The Long Dream* (1958) deals with racial prejudice in the South. *Eight Men* (1961) is a collection of short stories. His nonfiction is that of a deeply subjective reporter: *Twelve Million Black Voices* (1941), a short illustrated history of the blacks; *Black Power* (1954), an account of his visit in 1953 to the Gold Coast (now Ghana); *The Color Curtain* (1956), a report of the Asian-African conference at Bandung in 1955; *Pagan Spain* (1957), personal observations; and *White Man, Listen!* (1957), lectures on the international race issue. His fame rests upon his championing of the black cause, chiefly through his skill as a novelist. His writing may be said

to contain more anger than art, but despite some unevenness of style he sustained in his works a narrative power and a disturbing emotional impact that brought him lasting recognition.

WRIGHT, Silas, American political leader: b. Amherst, Mass., May 24, 1795; d. Canton, N.Y., Aug. 27, 1847. He graduated from Middlebury College, was admitted to the bar in 1819, and began practicing in Canton. From 1824 to 1827 he was in the New York State Senate, where he became a leader of the Bucktail Democrats (opposed to DeWitt Clinton) and a member of the Albany Regency group. (See ALBANY REGENCY; BUCKTAILS.) In 1827 he went to the House of Representatives in Washington, where he favored protection and helped frame the 1828 "tariff" of abominations" (which later, in 1842, he admitted was "a great error"). He resigned his House seat in 1829 to become comptroller of New York State and resigned this office in turn in 1833 to complete the term of William L. Marcy (who had been elected governor of New York) in the United States Senate. Reelected senator in 1837 and 1843, Wright was held in high esteem by his colleagues. He was a logical and powerful reasoner, of unflinching integrity, and ready to sacrifice his inclinations to the needs of the Democratic Party. His contemporaries referred to him as "the Cato of the Senate" and "the Cato of the Union," and Arthur M. Schlesinger characterized him as "a preliminary sketch for Abraham Lincoln."

As senator, Wright opposed rechartering the Bank of the United States, urged an independent treasury system, and saw the bill for the latter passed in 1840. Refusing President John Tyler's offer of an appointment to the United States Supreme Court in 1844 and the nomination for vice president on the Democratic ticket in the same year, he resigned his seat in the Senate to run for governor of New York, winning the election and carrying the state for the Democratic presidential candidate, James K. Polk. As governor Wright alienated the landlord interests by advocating rent reform but also lost popular support by suppressing the antirent disturbances. He was renominated in 1846 but lost to his Whig opponent, John Young.

WRIGHT, Wilbur, b. Millville, Ind., April 16, 1867; d. Dayton, Ohio, May 30, 1912; and **Orville**, b. Dayton, Ohio, Aug. 19, 1871; d. there, Jan. 30, 1948; American inventors. Their father, Milton Wright, was a bishop of the Church of the United Brethren in Christ. Though both brothers completed high school courses, neither graduated formally; Wilbur did not return from Dayton to Richmond, Ind., where the family had been living, to receive his diploma, and Orville, in his final year, took a special course. Neither Wilbur nor Orville ever married. As a youth Orville became interested in printing and in 1889 started the *West Side News*, in which Wilbur joined him; it was printed on a homemade press. In 1893 the two brothers opened a shop for the sale, repair, and manufacture of bicycles.

First Glider Experiments. After the death (1896) of Otto Lilienthal, the German engineer, news of

whose gliding experiments Wilbur and Orville had followed eagerly, they thought of taking up gliding where Lilienthal had left off. Their interest in aerodynamics had been aroused in childhood by a toy helicopter powered by rubber bands. Finding few books on the subject in the Dayton Public Library, they wrote in 1899 to the Smithsonian Institution at Washington for a bibliography. Books they then read included Lilienthal's *The Problem of Flying* and *Practical Experiments in Soaring*; and *Progress in Flying Machines*, by Octave Chanute, the best historian of attempts to fly. Wilbur came to know Chanute, at first by correspondence, and for years the brothers kept him informed of their progress.

Orville thought a flying machine should be under better control than any yet tried, and that for sidewise balance there should be a way to present the right and left wings at different angles to the wind; Wilbur hit on a practical way to do this, by twisting or warping the wings. To test this method, they built, in July 1899, a small kitelike glider with superposed surfaces, each 5 feet from tip to tip. It showed that their system of control was effective, and they then planned a man-carrying glider.

From United States Weather Bureau wind records they found that Kitty Hawk, N.C., was one of the breeziest places in the country; they also learned that the area had sand hills, free of growth and suitable for gliding. They went there in 1900 with their first man-carrying glider, which was 18 feet from tip to tip. It included a feature not on any previous glider, a horizontal front rudder or elevator about 4 feet in front of the lower main plane; the rear edge could be raised or lowered for fore-and-aft balance. A cradle, in which the operator lay, was connected with wires in order to give a spiral twist to the wings; a movement of the body of 2 or 3 inches from one side to another was enough to give all the twist needed. It was the brothers' intention to fly the glider as a kite, with a pilot aboard, to gain practice, but they found this possible only when the wind was at least 25 miles an hour. The glider failed to perform in lifting as had been calculated from the Lilienthal tables of air pressure, but they were encouraged by the way their method of control worked. Before leaving camp for the year, they took the machine to Kill Devil Hill near Kitty Hawk and made about a dozen glides down the side of the hill. Disappointed with the glider's lifting ability, they determined to return the next year with a larger machine having wings of deeper curvature.

Further Research. Since the results obtained did not at all agree with the estimated values computed from Lilienthal's tables and other accepted tables of air pressure, the brothers wondered if Lilienthal's figures and all scientific books on the subject could be wrong. Toward the end of 1901, they experimented with miniature wings in a 6-foot wind tunnel, testing more than 200 types of wing surfaces set at different angles. They measured monoplane, biplane, and triplane models, and models in which one wing followed the other; they measured the lift produced by different aspect ratios (the ratio of span to chord) and found that the greater the span in proportion to the chord, the more easily the wing would be supported; they measured thick and thin surfaces. Among other things, these experiments proved the undesirability of the sharp edge at the front of a wing, then advocated by

others (although it has now been readopted for supersonic flight). They also learned that there was a loss in lift having one wing above another.

These experiments marked the turning point in attempts by man to fly. The Wrights now knew what no man had ever known before: how to compile tables of figures from which one might design an airplane that could lift itself and fly. Their 1902 glider, built from their own calculations, had a wing span of 32 feet, 10 feet more than one used in 1901, but the most noticeable change was the addition of a tail with fixed twin vertical vanes. In further experiments they discovered that the tail is a balancing device needed to supplement the presenting of the wings at different angles to the wind—the basic scheme of control used in all airplanes today. With the 1902 machine the Wrights made glides of more than 600 feet, and they could glide at a smaller angle of descent, closer to the horizontal, than the hawks that they observed. When they built their first power machine the next year, equipped with a motor of their own make, they felt sure it would fly.

Powered Flight. On Dec. 17, 1903, at Kitty Hawk, Orville made the first flight of 120 feet; Wilbur, in the fourth and longest, made 852 feet in 59 seconds. During 1904 and 1905 they made further experiments at a field near Dayton, Wilbur achieving a flight of 24 miles in 1905. They closed a contract with the United States War Department for the first army plane in 1908, for which tests were completed in 1909. Meanwhile, in 1908, a Wright company was formed in France, where Wilbur gave demonstrations and trained pilots. In 1909 Orville flew in Germany, and Wilbur made sensational flights in New York City in connection with the Hudson-Fulton Celebration. By the end of 1909 an American Wright company had been organized. In 1948 the original plane flown at Kitty Hawk in 1903, which had been temporarily lent to the Science Museum at South Kensington, London, was returned to the United States for permanent exhibition in the National Museum at Washington, D.C.

WRIGHT, William Hammond, American astronomer: b. San Francisco, Calif., Nov. 4, 1871; d. San Jose, May 16, 1959. He graduated from the University of California in 1893 and then pursued graduate work at the University of Chicago. In 1897 he was appointed assistant astronomer at Lick Observatory, University of California, and was in charge of the observatory's expedition to the Southern Hemisphere (1903–1906). He was made astronomer in 1908 and served as director of the observatory from 1935 to 1942. Wright won wide attention for his work on the gaseous nebular spectra and, pioneering in the use of infrared photography for astronomical purposes, secured the first clear pictures of Mars, on the basis of which he made tentative explanations of some of the planet's characteristics.

CULVER PICTURES

ton, Ohio. Wilbur (left) and Orville Wright, taking turns, made four powered flights at Kitty Hawk on Dec. 17, 1903.

ton, Ohio. The Air Force Logistics Command Headquarters, Air Force Museum, and 51 other tenant organizations share its 8,023 acres. It has twin airfields, now rare. The areas, formerly separate, include Wright Field (named for Orville and Wilbur Wright), and Patterson Field (named for Lt. Frank S. Patterson of Dayton, who was killed near the base on June 19, 1918, while testing a device for synchronizing machine gun fire with aircraft propellers). The base may be called the birthplace of Air Force research, development, and logistics. Aviation "firsts" originating here include the first solo instrument takeoff and landing and the first human ejection from a speeding aircraft.

RONALD GREEN

WRIT, rit, in Anglo-American law, a documentary order issued in the name of a court or of an executive officer, directing the person to whom it is addressed to do or refrain from doing a particular act described in the writ. The two principal categories are *prerogative writs* and *writs of right*.

Prerogative writs, frequently referred to as extraordinary remedies, are issued in the discretion of the court upon a showing that no other remedy adequate to the circumstances is available. Common examples of prerogative writs are mandamus, prohibition, quo warranto, habeas

corpus, and certiorari. The writ of mandamus is a command to a public official to perform a duty required by his office. The writ of prohibition forbids an inferior court or tribunal from continuing to conduct proceedings over which it has no rightful authority. The writ of quo warranto is an order to show by what authority an office or franchise is held. The writ of habeas corpus, in its most common form, is an order to bring before the court a person held in custody so that the legality of his restraint may be determined. The writ of certiorari issues from a superior court in order to review the record of evidence presented in the case before an inferior court. See also MANDAMUS; QUO WARRANTO; HABEAS CORPUS; CERTIORARI.

In contrast to these discretionary writs, which historically were a matter of the king's prerogative, writs of right were a category which the king was bound to issue under the terms of Magna Carta of 1215. The two main kinds of writs of right are *original* and *judicial*. Original writs were issued, without any order of court, from the King's Chancery. They are called original writs because they were the means of initiating every action at common law. The subsequent proceedings and the entire theory of the case were rigidly governed by the kind of original writ used, giving rise to the concept of the forms of action at common law. While the system of original writs has been abolished in England and was never widely used in the United States, the "form of action" concept still has some influence on Anglo-American law in spite of widespread procedural reforms which began in the 19th century. Judicial writs are issued by courts as a means either of initiating proceedings, of furthering proceedings in progress, or of executing the judgment of the court at the conclusion of the main proceedings. The most common judicial writ for initiating proceedings is the writ of summons, which demands the appearance of a specified person at a stated time before a court or officer and which generally specifies the complaint against him.

Much of the history of Anglo-American law can be told in terms of the supplanting of one form of writ by another (or by the fictionalized use of another) and the modification or abolition of many of the older writs in an effort to develop simpler and more effective legal processes. Hence nomenclature and usage vary widely among the many legal systems in the United States and the Commonwealth of Nations.

WRIT OF ASSISTANCE, general search warrant issued to British customs officers by the superior courts of the American colonies. Writs were used to enforce the trade and navigation laws, and they authorized officials to search for smuggled goods without specifying either the location or the goods.

First issued in Massachusetts in 1751, writs

of assistance aroused no controversy until new ones were applied for ten years later. They were opposed as unlawful by Boston merchants, but instructions from England supported their legality in 1762. The Townshend Acts (1767) again authorized writs of assistance, and customs officers in all 13 colonies were directed to secure them from the superior courts. The writs were challenged in the courts in every colony, and many courts refused to issue them. Writs of assistance became an important colonial grievance.

WRITERS' CRAMP is a spastic condition of the writing muscles of the hand, first described by Sir Charles Bell in 1830. The ailment has also been known as *scriveners' palsy*. The disorder is associated with fatigue and prolonged use of these muscle groups. It has been classed as an occupational neurosis and compared to similar muscle palsies in other exacting occupations: for example, those of the calf muscles of professional dancers, the thumb muscles of tailors, and the thumb and forefinger muscles of telegraphers. There is no specific organic disease of the muscles, tendons, or nerves in the sufferer from writers' cramp; it is simply that he wants to write but cannot. Other unrelated motions of the hand can be performed with ease. Accurate diagnosis of the case is important, since sclerosing diseases of the brain, various types of neuritis and neuralgia, and at times inflammatory rheumatism can simulate this condition. A French school (François Thiebaut and others) in the *Revue Neurologique*, vol 101, pp. 230-234 (Paris 1959), has described an electromyographic method of diagnosing writers' cramp.

Treatments of writers' cramp have been many and varied. The simplest device is rest, which may require up to six months. During this time, psychotherapy may be helpful. The electric typewriter, the teletype, and many other types of duplicating machines have made this condition of less clinical importance.

REAUMUR S. DONNALLY, M.D.

WRITING, *rī'ting*, the communication of ideas by means of conventional symbols that are traced, incised, drawn, or otherwise formed on the surface of some material such as stone, metal, bamboo, papyrus, parchment, or paper. Although some animals communicate with one another by means of sound, only man communicates by means of writing; it is thus more peculiar to man than speech, which it supplements. Writing gives permanence to men's knowledge and enables them to communicate over great distances. Hence it is a necessary condition of civilization as we know it. The complex society of a higher civilization would be impossible without the art of writing.

ORIGINS

History does not throw much light on the origin of writing. We do not know who the inventor was; there probably were many. Nor do we know where or how far in the distant past the art first arose.

Mythology.—Because of the great value set upon the art of writing and the magical power it exercises over the unlearned, this precious possession of man was regarded as something beyond his unaided powers of creation. The ancient Egyptians ascribed the invention to Thoth, the god who invented nearly all the cultural elements, or to the goddess Isis. Babylonian mythology attributed it

Nebo (Nabu), Marduk's son, who was also the god of man's destiny. The ancient Chinese attributed it to the dragon-faced Ts'ang Chieh; the ancient Greeks, to Hermes or various other mythical characters, particularly Cadmus; the Romans, to their god Mercury. The Teutonic god Woden (Woden, Wuotan) was credited with the invention of runes (q.v.), and the Celtic god Ogma (Ogmios) with the invention of ogam (q.v.). In pre-Columbian America, in Mexico, the Aztecs attributed writing to their god Quetzalcoatl. The ancient Indians and many other peoples also believed in the divine origin of their script. In the Bible there is no reference to the origin of writing, although there are passages dealing with the origin of other arts such as language, agriculture, music, and metallurgy; there is, however, a post-Biblical tradition which attributed the creation of writing to Moses.

Primitive Methods of Communication.—From earliest times we can detect various parallel efforts to develop methods of human communication. Language led to the development of acoustic methods. The range of the human voice was extended by signaling with drums, horns or trumpets, flutes, and other instruments. Acoustic methods of communication, in turn, are allied with optical visual methods such as gesture, mimicry, and signaling with light, fire, smoke, and other means.

There were also the carved message sticks of the primitive Australians, which carried intertribal messages; the notched sticks of ancient Scandinavia, which served similar purposes; and similar sticks used in ancient Russia, Italy, North America, and elsewhere, and still used in Africa, China, and Australia. Notched sticks, or tallies, were actually used by the exchequer of England down to 1832 as receipts for money paid into the treasury.

Property marks, pottery marks, tattooing, and similar distinguishing marks, even gravestones, belong to the same general category of visual communication. These were also memory-aid devices. The Australian churingas, sacred tablets covered with geometrical markings, were used as notations or memory aids for recounting the traditional myths of the origin of the tribe.

Of the knot devices—which were employed in ancient Tibet, Japan, Bengal, Persia, and Mexico, and are still used in East Africa, Polynesia, Peru and other places—the most celebrated is the quipu, or knotted cord, found in the ancient graves of Peru, which recorded administrative facts, registered the amount of taxes, and performed similar functions by the use of strings and knots of varied length, thickness, and color. The wampum belts of the North American Indians consisted of cords of colored shell beads, occasionally arranged in pictorial drawings; they served as legal instruments in ratifying treaties, confirming alliances, concluding contracts, and the like (white stood for peace, red for war or anger, black for death or misfortune, and yellow for gold or tribute). The calumet, or sacred decorated-reed tobacco pipe, was another Indian memory-aid device used for signifying war or peace.

Sympathetic Magic.—The various devices described in the preceding paragraphs may be regarded as prodromes of writing. It was a great step forward when, instead of using tangible objects as a means of communication, man began to "write"—that is, to scratch, draw, paint, or incise pictures of things. It may be assumed that at the beginning perishable writing materials were used

—such as leaves, bark, and wood. Needless to say, no such specimens have come down to us.

Of the prodromes of writing, the oldest extant are the devices connected with sympathetic magic. The world of primitive man was and is a world of magic. At some remote time in the Upper Paleolithic period, perhaps about 20,000 B.C., the cave dweller in southern France and northeastern Spain drew sketches of his prey—bears, buffaloes, deer, and other animals—on the wall of his cave and colored them with earths and vegetable dyes. He also drew sketches on the bones of the animals he killed and on rude stone implements. Some of these sketches are remarkable for their realism. (See PALEOLITHIC ART.) We may have here the beginning of art but hardly the beginning of writing. In the mind of the prehistoric man, the picture of the prey was in some way identified with the living animal; when the hunter pierced the image with his spear, in his mind the success of the coming hunt was assured. To this day Australian natives substitute sand drawings of the prey for the prehistoric ochre painting.

Probably to be included in the category of sympathetic magic are the various geometric signs or conventional figures of men painted or engraved on stones (termed petroglyphs) of megalithic tombs and similar monuments found in the Mediterranean and other regions, as well as on rocks found the world over dating from the Old Stone Age down to modern times. Expert opinion differs, however, as to whether the numerous river pebbles of the Azilian culture of the Middle Stone Age, containing dots and lines painted with peroxide of iron, also belong in this category.

CLASSIFICATION

Prehistoric man did not develop writing. However, as he became more civilized and social intercourse and trade increased, while magic and religion developed further, he doubtless felt the need of a more permanent and better organized form to replace his pictures, symbols, marks, and other means of communicating thought. We cannot know all the links in the chain of development of writing from its rude beginnings to the fully developed alphabetic script. Difficulties arise, too, when we try to fix in detail the stages of this development, to find exact terms for the various stages, to define them, and to ascribe individual scripts to them. We may attempt to distinguish two, three, or more groups of scripts, but we find that some of those that might be assigned, for instance, to Class 1 have features of Class 2 or 4, while others also assignable to Class 1 might be regarded as transitional from a memory-aid device to Class 3. In short, no scheme of classification is complete or wholly satisfactory.

The simplest method divides all scripts into two categories: ideographic and phonographic. Ideographic script is concerned with the representation of objects or ideas; phonographic, with the representation of sounds or spoken words. Another method distinguishes three historical stages: the figurative, the transitional or conventional, and the alphabetic. In the first stage, writing is supposed to be pictorial or immediately representative of objects. In the transitional period comes symbolical writing, in which abbreviated pictures are transformed into arbitrary symbols, first of things and in due time of sounds and words. Finally, when phonetic writing prevails, sounds are represented first in syllables and afterward in alphabetic symbols or letters.

Left: Ideographic writing, as in cuneiform or Chinese, uses characters to represent objects or ideas. Such symbols become standardized over a period of years.

Below: The Greek alphabet is an excellent example of phonographic script, in which symbols represent the sounds of vowels and consonants. This fragment is a copy of a document from the 3d century, B.C.

New York Public Library

A more complicated and more complete method divides all writing into four stages of development, though it would be inaccurate and misleading to represent these stages as epochs in the progress of writing. Several of the scripts of Class 3 in this arrangement are considerably older than various known scripts of Class 2. Some scripts of Class 4 (the syllabic scripts) derive from scripts of Class 3, but others (the alphabetic scripts) are probably an independent invention. Indeed, the alphabetic system (Class 4b) belongs to a much earlier period than the great majority of scripts belonging to the other classes, except for the main scripts of Class 3. With this proviso, the stages of writing may be indicated schematically as follows:

Class 1: Iconography.—This consists of drawings of natural objects. The pictures represent the things shown: the sketch of an animal would represent the animal; a circle might represent the sun. The drawings are disconnected and fragmentary pictures, and give a static impression. The best known among these scripts are those of some North American Indian tribes.

Class 2: Synthetic or Ideographic Writing.—This consists of a series of pictures telling connected stories. Today, with action photographs, motion pictures, and comic strips, the introduction of action into pictures seems a small thing. As a matter of fact, it was a very important development when the "writer" began to "write" picture stories—that is, when he began to make pictures tell stories. From this arose the synthetic or ideographic type of writing, which can best be

studied in the scripts of primitive tribes in present-day Polynesia and Australia, in West Africa, among the Yukaghirs of northeastern Siberia, and particularly among the North American and Central American Indians.

Class 3: Analytic or Transitional Systems.—Neither of the two previous groups constitutes, or can be expected to constitute, a complete system of writing. Some scripts which can constitute a complete system and have been incorrectly termed ideographic may have been ideographic in origin, but even in the earliest inscriptions that have come to light they are partly ideographic (using pictographic symbols which suggest ideas or represent objects) and partly phonetic, the components being combined in various ways. The term "pictographic," also given to these scripts, is even less appropriate than ideographic. Another term used for them is "transitional," since they represent the transitional stage between pure ideographic writing and the pure phonetic system. A still better term is "analytic."

In the systems belonging to this category, a standardized picture, a pictogram that was as a rule easily reproduced and familiar to those using it, was selected by convention from the many that had been used for a particular thing and became the accepted symbol for this thing. At least originally, the name of the object, whether at rest or in some particular form of motion, was closely identified with the picture. Associated with pictograms were signs of a different type known as ideograms, which represented ideas, qualities, actions, and sometimes objects, none of which could be clearly

portrayed by a pictogram. The most famous scripts of the ancient world belong to this category, among them those of the Mesopotamian peoples, the Egyptians, and the Cretans (Minoans); the Indus Valley script; the Hittite hieroglyphics; and the Chinese, Mayan, and Aztec scripts. Of these, the Chinese system is the only one still in use. See ASSYRIOLOGY; CHINA—10. *Language*; CUNEIFORM WRITING; HIEROGLYPHICS, EGYPTIAN; HIEROGLYPHICS, HITTITE AND CRETAN; HIEROGLYPHICS, PRE-COLUMBIAN AMERICAN.

Class 4: Phonetic Systems.—In the iconographic and pure ideographic scripts, the symbols can be "read" in any language; there is no necessary connection between the symbols and the speech or sounds. Hence, we can examine and understand the pictorial and ideographic signs of any people who have ever existed without knowing what words they spoke. On the other hand, in phonetic systems, writing has become the graphic counterpart of speech. Each element of writing corresponds to a specific element of speech, a sound in the language, and the symbols cease to be self-evident pictures. The individual signs may be of any shape. Generally there is no connection between the external form of the symbol and the sound it represents, and the script must be explained through the language in which it is written. Phonetic systems may be subdivided into syllabic (Class 4a) and alphabetic (Class 4b):

Class 4a: Syllabic Writing.—In the systematic syllabaries, the individual signs represent syllables, the smallest elements of words that can be isolated and spoken. Thus, as the written symbols, or phonograms, of a syllabary are monosyllabic in value, a word of one syllable would be represented by one symbol, and a word of two or more syllables would be represented by two or more symbols or phonograms. The syllabic systems of writing developed more readily and appeared as new creations more often than the alphabetic.

In the case of a language that has many clusters of consonants, the syllabary becomes a cumbersome mode of writing, especially because it usually contains only open syllables (those made up of a consonant plus a vowel) or vowels when these constitute syllables. This is particularly noticeable in both the ancient Cypriote syllabary, in which the Greek word *ptolin* (city) was transliterated *po-to-li-ne*, and in the Minoan Linear B script deciphered in 1952. Needless to say, such a system would require a much greater number of symbols than alphabetic writing.

Of the syllabic scripts, the Japanese (of which there are two varieties, hiragana and katakana, both of which evolved from Chinese writing, in the 9th and 8th centuries A.D., respectively) are still in use. Some modern syllabaries have been devised by missionaries in West Africa, North America, China, and other countries. See also JAPAN—18. *Language*.

Two other scripts evolved from more complicated syllabaries and, without achieving true simplicity, almost reached the stage of alphabetic writing. One was the historically very important Old Persian script, the official script in cuneiform characters of the dynasty of the Achaemenids, under whose rule, from the middle of the 6th century B.C. until the victories of Alexander the Great, the ancient Persians attained the zenith of their power. The other was the Meroitic script, used in two varieties (monumental and cursive) from the 2d century B.C. to the 4th century A.D. in Meroë in ancient Nubia. While the Old Persian cuneiform

script was a mixture of alphabetic and syllabic signs, the Meroitic contained only two syllabic symbols, all the other signs being alphabetic.

Class 4b: Alphabetic Writing.—This may be fairly regarded as the finished product of the whole train of development. Alphabetic writing is the most highly developed and the most convenient system of writing, and it is readily adaptable to almost any language. An alphabet is a collection of a small number of symbols, generally between 20 and 40, known as letters, which are intended to represent the various phonetic elements of human speech, consisting of vowels and consonants.

Alphabetic writing is now almost universally employed by civilized peoples. No other system of writing has had so extensive, so intricate, and so interesting a history. It is now generally agreed that all existing alphabets, as well as those no longer used, derived from one original alphabet, the North Semitic, which probably originated about the 18th century B.C. in the region of Palestine and Syria. In its broad outlines, the story of the alphabet since the end of the 2d millennium B.C. is not very hard to trace, but many details of the development of some individual alphabets are still uncertain. For the history of the alphabet, see the article ALPHABET and separate articles on the individual letters.

STYLES AND DIFFUSION OF WRITING

Epigraphy and Paleography.—Although writing is not regarded as a separate branch of study, it forms the main basis of two important fields, epigraphy and paleography. Epigraphy deals with monumental or lapidary writing, in which the chief considerations are permanence and beauty, including evenness and proportion; speed of execution plays only a minor part. Even in alphabetic scripts the characters usually appear as separate units without ligatures. Whenever possible, they tend to be made up of independent strokes or scratches of the chisel, with as few curves as possible.

In the study of paleography, two styles of writing may be broadly distinguished: the ordinary cursive hand, informal or common, employed in everyday life; and the carefully written literary or book hand employed by trained scribes for copying literary works. In cursive or current writing, the chief considerations are speed and utility. Indeed, the current or running hand, as seen for instance in Egyptian hieratic and demotic writings or in Chinese or Latin cursive scripts, naturally assumes a less precise form. The shapes of the characters change quickly, sometimes within a generation; strokes become slurred; angles become more and more curved; superfluities are dropped; and ligatures are used. In the formal book hand there is greater emphasis on legibility, combined as a rule with uniformity; this results from the unhurried operation of a skilled craftsman employing characters that are stabilized in form.

The two classes, the current or informal hand and the formal or book hand, were not always kept distinct. Books were copied in the current hand by a scholar for his own private study, or else by a scrivener or copyist, and quite often the original was written in the current hand by the author himself. On the other hand, documents that would normally be written in the current hand might, for some special reason, have been written in a book hand or formal script, and this

hand was sometimes employed for more important official letters or even for private correspondence. These are, however, exceptional cases. Generally speaking, there always existed a degree of competitiveness between the book hand or formal script and the natural, informal current hand. Both styles, and the monumental style also, were based on the same script and were used concurrently, but the different purposes of the proposed documents—for example, for a presentation or some other special occasion when something ornate might be required—set different stylistic ideals before the scribe. The different materials used, and particularly the tools employed, also favored different styles of writing.

See also ARAB CIVILIZATION—2. Language; ILLUMINATED MANUSCRIPTS; PALEOGRAPHY.

Idea Diffusion or Stimulus Diffusion.—The theory of idea diffusion or stimulus diffusion provides the best explanation of the origin of some important scripts in the ancient world, such as Egyptian hieroglyphics and the Chinese script. According to this theory, after writing had developed in Mesopotamia, the generic idea, when it reached Egypt and China, induced some important personality in each of these countries to invent a script for Egyptian and Chinese speech. This theory may also explain the origin of the Teutonic runes and the Celtic ogams, and perhaps several other scripts.

Alphabets and Religion.—While it is true to say, in certain instances, "The alphabet follows trade," and, in others, "The alphabet follows the flag," the diffusion of the alphabet throughout the world for about 2,000 years may be summed up in the aphorism "The alphabet follows religion." Interestingly enough, while few examples of the Latin alphabet survive from the first five or six centuries of its existence, from the 1st century B.C. onward Latin inscriptions become too numerous and too widespread geographically to be counted. The Latin language and script were carried by Roman legionaries and imperial officers to all parts of the vast Roman Empire, particularly to the regions which were not Hellenized. In later centuries, however, churchmen and missionaries carried Latin language and script still farther afield. Catholic Rome was then the light of the Western World, the center from which religion and learning were disseminated to all parts of western, central, and northern Europe. The ascendancy of Latin led to the adoption of the Latin alphabet by a large majority of nations, and it was adapted to tongues of the most diverse linguistic groups.

Two alphabets, the Cyrillic and the Glagolitic, were employed for writing the early Slavonic language. Of the two, the Cyrillic (based on the Greek uncial alphabet of the 9th century A.D.) developed in the course of time into the national scripts of those Slavonic peoples who accepted their religion from Byzantium, namely the Russians, White Russians, Ukrainians, Bulgarians, and Serbs. Through the Russian script, the Cyrillic alphabet has also been adopted for several Finno-Ugrian, Turki, and Iranian languages. On the other hand, Roman Christianity brought the use of the Latin alphabet to the Poles, Czechs, Slovaks, Lusatians, Wends, Slovenes, and Croats. The most interesting case is that of Serbo-Croatian, which is a single speech although it is written differently by the Orthodox Serbs and the Roman Catholic Croats. Thus the line of demarcation between the Eastern and the Western

churches runs right through the Slavonic ^{ies.} With one small exception (the Roman Catholic Slavs of the western Balkan Peninsula still employ the Glagolitic script for liturgical purposes), wherever the church is Roman the Latin alphabet is used; where it is Orthodox, the Cyrillic alphabet is used. See also ALPHABET—8. Slavonic Alphabets; CYRILLIC ALPHABET.

In the history of the alphabet, the Aramaic branch occupies in the East a place comparable with that of the Latin alphabet in the West. From the 7th century B.C. onward, and particularly in the second half of the 1st millennium B.C., the Aramaic language and script became by far the most important and widespread in the whole of western Asia. In the late 3d century B.C. and during the succeeding centuries, numerous Aramaic offshoots became distinct entities. The hundreds of direct and indirect descendants of the Aramaic alphabet can be divided into two main groups, those used for the Semitic and those for the non-Semitic languages. Many of these scripts exemplify the aphorism that "the alphabet follows religion." This is particularly the case with the Hebrew and Arabic scripts, but it is also largely true of the Syriac-Nestorian, Mandaean, Manichaean, Pahlavi, Armenian and Georgian, and the Buddhist scripts of the Indochinese Peninsula.

The Syriac-Nestorian script was used by the extremely active Nestorian missionaries, who carried their religion, their Syriac language, and their script into the Kurdistan highlands, southern India, and Turkestan, and to other Turki as well as Mongol tribes of Central Asia; they even penetrated into China. The script of the Manichaeans also spread with their religion, which, from the middle of the 3d century A.D. to about 1200, was one of the most widely disseminated in the world. Similarly, the Pahlavi scripts of the sacred pre-Islamic literature of the Iranians were disseminated with Zoroastrianism and are still used for liturgical purposes, particularly by the Parsis of India. The Buddhist monks likewise made their scripts the vehicle of their culture; a unique empire was built up, based not on political and military unity, but on the common cultural and spiritual life of peoples who were more or less independent politically. Buddhism, indeed, played a role in Southeast Asia similar to that of Roman Christianity in Europe in the Middle Ages.

The Arabic alphabet is, after the Latin script, the one now most generally used in Asia and Africa. As the language and script of the Koran, the holy book of Islam, Arabic spread with the expansion of this religion as far as western and central Africa, southern Europe, southern Russia, India, and Indonesia. The script has been adopted for, and adapted to, a great number of Asian and African tongues and in times past, in Europe, to such languages as Spanish and Bosnian Slavonic. WROCLAW, vró'sláf, is a large industrial city in Poland. Called *Breslau* in German, it was the historic capital of Silesia. It is now the capital of Wrocław province. Wrocław lies on the Odra (Oder) River, 190 miles (310 km) southwest of Warsaw and about 280 miles (460 km) from the Baltic Sea. The city grew during the early Middle Ages on a small defensible island in the river, and became the seat of the bishop and the site of the cathedral in the 13th century. In that century, however, a commercial city developed under German influence on the south bank of the river. It was laid out on a pattern of rectangular blocks, with a large central marketplace where the remarkable Gothic town hall was built in the 14th–15th centuries. The new town absorbed the island town in the 14th century.

The growth of Wrocław was assisted by its excellent communications and by the rich farmland that surrounds it. The city passed to Bohemia in 1335, then to Austria in 1526, and subsequently to Prussia in 1742. In the 19th century it developed into an important industrial city, with mechanical engineering and textile industries predominating. In World War II the city was defended by the Germans against the Russians for a short time and suffered severe damage. The historic monuments, however, were preserved. In 1945, Wrocław was returned to Poland. Population: (1964 est.) 469,400.

NORMAN J. G. POUNDS, *Indiana University*

WRONG, rông, **George Mackinnon**, Canadian historian: b. Grovesend, Ontario, Canada, June 25, 1860; d. Toronto, June 29, 1948. He graduated from the University of Toronto in 1883, was ordained in the Anglican ministry, and began to teach church history and other courses at Wycliffe College in Toronto. Nine years later he joined the faculty of the University of Toronto, where he was professor of history from 1894 to 1927. Wrong was an impressive and popular teacher, but even more important was his influence in raising the standards of historical scholarship in Canada. In 1897 he founded, and for 30 years edited, the *Review of Historical Publications Relating to Canada* (incorporated in the *Canadian Historical Review* in 1920); and from 1905 to 1922 he was editorial secretary of the Champlain Society, publishing rare materials on Canadian history. He was also coeditor of the *Chronicles of Canada* series (32 vols., 1914–16) and contributed *The Conquest of New France* (1918) and *Washington and His Comrades in Arms* (1921) to the *Chronicles of America* series. Among his other books are *The Rise and Fall of New France* (2 vols., 1928), *Canada and the American Revolution* (1935), and *The Canadians, the Story of a People* (1938).

WROŃSKI, wrón'ya-skē, **Józef Maria** (real surname **HOENE**; known as **HOENE-WROŃSKI**), Polish mathematician and philosopher: b. near Poznań, Poland, Aug. 24, 1778; d. Neuilly-sur-Seine, France, Aug. 9, 1853. After serving in the Polish and Russian armies, he studied philosophy and mathematics in Germany and settled in Paris about 1800. At first a disciple of Immanuel Kant, whose metaphysics he sought to reconcile with the calculus of Gottfried Wilhelm von Leibniz, he gradually developed a social philosophy, known as messianism, to resolve the conflicting views of liberal and conservative factions, and he held that absolute truth might be established by

means of mathematical formulas. He applied his system to mathematical analysis, the theory of numbers, and the theory of probabilities. He is best remembered for his "Wronskian determinants" (see **DETERMINANTS**), but he contributed to the knowledge of celestial mechanics and several branches of physics. The extravagances and mysticism of his messianism kept him from having much influence in his own time, but reappraisal of his mathematical contributions has added substantially to his reputation.

WROXETER, rók'sə-tər, village, England, in Shropshire, six miles southeast of Shrewsbury. Here are the remains of the Roman Viroconium (Uriconium, Virconium), originally (48 A.D.) a base camp guarding the point where Watling Street crossed the Severn River. About 75 A.D. a civilian town was founded, occupied by the Cornovii. It was partially rebuilt about 120 A.D., and by the mid-2d century was the fourth largest in the country. By the 5th century, however, it had been abandoned with the founding of the town of Shrewsbury by the Anglo-Saxons; the ruins became quarries of building stones. The principal visible remains are parts of the 2d century baths and the forum. A small museum contains objects found on the site. Pop. (1963) 993.

WRYBILL, rī'bīl, a plover (*Anarhynchus frontalis*) of New Zealand noted for its strange bill, which is bent sideways to the right along its distal half. The bird measures eight inches in length and is gray above and white below with a black band across the breast. Except for the bill, it resembles many ring-necked plovers. The deviation remains unexplained, although some ornithologists believed at one time that it was an adaptation for searching under rounded stones.

M. F. Soper from National Audubon Society

The wrybill of New Zealand is distinguished by a strange beak, always bent to the right.

Modern studies have failed to substantiate this or to reveal any abnormality in behavior, but the wrybill is also unusual in that it normally lays only two eggs, whereas most plovers usually lay four.

WRYNECK, rī'nèk, one of two species forming the subfamily Jynaginae of the woodpeckers. Wrynecks are considered to be primitive mem-

bers of the woodpecker family because they lack many of its specialized characters, such as the stiffened tail, and do not bore for food or dig their own nest holes. They differ also in the texture of their plumage, which is much softer than that of the woodpeckers and differently colored, being grayish or reddish brown and very delicately mottled. In fact, they resemble superficially a small nightjar or a songbird much more than they do a woodpecker. The name wryneck refers to their ability to twist and contort the neck at extraordinary angles. The better known wryneck (*Jynx torquilla*) measures six inches in length and is found virtually throughout the forests of Eurasia except in the tropics; it also inhabits northwestern Africa. In the rest of Africa it is replaced by the slightly larger and more colorful *J. ruficollis*. See also WOODPECKER.

WU-HSI. See WUSHI.

WU P'EI-FU, wō'pā'fō', Chinese general: b. Penglai, Shantung, China, 1878; d. Peking, Dec. 4, 1939. Although interested all his life in philosophy and poetry, he trained for an army career, graduating from the military academy at Tientsin in 1898. Under the Ch'ing dynasty he distinguished himself in several minor campaigns. After the republic was established in 1912, he became one of the most important war lords of northern China, the champion of the peace-loving middle classes and ruler of five major Chinese provinces. In addition to the monarchists, his chief opponents were Sun Yat-sen in the south, who was too weak to attack, and Chang Tso-lin in Manchuria. Wu P'ei-fu defeated Chang in 1922 but was defeated by him in 1924 when his own ally Feng Yü-hsiang defected to Chang. He suffered a final defeat when he attempted to oppose Chiang Kai-shek and the Kuomintang Army in their advance northward in 1926-1927. He then retired to a Buddhist monastery, refusing in 1937-1939 to aid the Japanese in their conquest of China or to become head of the puppet government they set up.

WU TAO-TZŪ, wō'dou'dzū', Chinese painter: b. about 700; d. about 770. There seems to be no reason to doubt that he was the greatest painter of the T'ang dynasty, but because he was above all else a Buddhist painter, most of his work perished, along with other similarly inspired art of the T'ang, during the anti-Buddhist persecutions of the 9th century. Literally nothing remains of Wu Tao-tzū's work; neither the questionable copies (Jungkung collection, Chicago; Abe collection, Osaka, Japan) nor the stone rubbings supposedly derived from his monochrome drawings can be true measures of his gifts. In 1952 Shujiro Shimada, a Japanese critic, finally demolished the claim that Wu was the painter of *Autumn Landscape*, in the Kōtō-in temple in Kyoto, Japan, assigning the work to Li T'ang, an artist of the Sung dynasty.

Wu may have used a curiously violent style, with draperies swelling out as if caught by a heavy wind. But this tradition contradicts what is generally known about Buddhist painting, and it has been argued convincingly that refer-

ences to Wu's so-called violent style meant merely that he used a free brush stroke and aspired to plasticity. It is conceivable that the wall paintings in the Hōryūji temple in Nara, Japan, may have had some relation to the art of Wu Tao-tzū; but these were damaged by fire just after World War II. Finally, some parts of the complex series of the cave temples of Tun-hwang, in the Chinese province of Kansu, may reflect the style of this lost master, all 300 of whose temple frescoes, apart from other works, have totally disappeared.

WALLACE BROCKWAY.

WU T'ING-FANG, wō't'ing'fāng', Chinese statesman and diplomat: b. Kwangtung Province, China, 1842; d. Canton, June 23, 1922. Following his early education at St. Paul's College in Hong Kong, he studied law at Lincoln's Inn, London (1874-1877). He then returned to the East and practiced law in Hong Kong. In 1882 he was appointed to the official staff of Li Hung-chang, then governor general of Chihli (Hopei) and grand chancellor of China, and in 1895 was one of the peace commissioners who negotiated the Treaty of Shimonoseki following the Chinese-Japanese War. He later occupied high government offices at Peking and, as minister of the board of punishment (1905-1906), reorganized the penal code. Wu T'ing-fang was minister to the United States in 1896-1902, 1908-1909, and 1912. He supported the revolution in 1911 and between 1916 and 1921 occupied various posts in the Canton government. His volume of impressions of the United States, *America Through the Spectacles of an Oriental Diplomat* (1914), received wide attention.

WUCHANG or **WU-CH'ANG**, wō'chāng', city, China, administrative and cultural center of the Wuhan urban complex (Wuchang, Hankow, and Hanyang) in east-central Hupei Province (see WUHAN). A port on the right bank of the Yangtze River at the mouth of the Han, Wuchang has tanning, paper manufacturing, and cotton- and silk-weaving industries, and is the seat of Wuhan University and of several colleges and institutes in the fields of agriculture, engineering, fine arts, law, water conservancy, and medicine, and a government mint. Commercial suburbs and the Hankow-Canton rail terminus extend along the Yangtze River north of the old walled city.

The oldest of the Wuhan cities, Wuchang dates from the 3d century A.D. It was a provincial capital under the Yüan (Mongol) dynasty in the 13th century and became the capital of Hupei Province in the 1660's. One of the first incidents of the Chinese Revolution of 1911 occurred here, and in 1927 the city was occupied by Nationalist forces. It became an independent municipality in 1935. From 1938 to 1945 it was controlled by the Japanese and was taken by the Communists in 1949. Pop. (1953) 400,000.

NORTON S. GINSBURG.

WUCHI MOUNTAINS or **WUCHI SHAN**, wō'jē', mountain system, China, occupying a major part of the Li-Miao Autonomous Chou in south-central Hainan Island, Kwangtung Province. They are inhabited chiefly by Li and Miao

borigines and are covered by virgin forest. At their highest elevation, the mountains rise to 11,118 feet. They are made up of five distinct ranges which extend, fingerlike, toward the south. The name means "five fingers" in Chinese.

BARUCH BOXER.

WUCHOW or **WU-CHOU**, wōō'jō', municipality, China, near the eastern border of the Kwangsi Chuang Autonomous Chou, about 120 miles west of Canton. Situated at the head of steamer navigation on the Si Kiang (West River) where it receives the Kwei, Wuchow is a port and trade center in the heart of an area producing bamboo, millet, rice, and wheat. It has a substantial chemical industry (producing sulphuric acid especially) and is a cotton-weaving and silk-processing center. It was opened to foreign trade in 1897, served as a United States airbase during World War II, and was briefly occupied (1944-1945) by the Japanese. Gold deposits are found nearby. From 1913 to 1946 it was known as Tsangwu. Pop. (1953) 110,800.

NORTON S. GINSBURG.

WUHAN, wōō'hān', municipality, China, capital of Hupei Province, on the Yangtze River at the mouth of the Han. Made up of the three important cities of Wuchang (east of the Yangtze), Hankow (north of the Han and west of the Yangtze), and Hanyang (south of the Han), Wuhan is the largest municipality in central China and serves as the focal point of economic and political activity in the rich Yangtze Valley region. It is a major transportation hub and industrial and administrative center, situated where the Peking-Canton Railway crosses the Yangtze, and is the site of two famous railway bridges, the Yangtze River bridge which connects Wuchang with Hanyang, and the Han River bridge connecting Hankow and Hanyang. Wuhan is the site of one of the earliest modern steel mills in China and is being developed as a new center of metallurgical and related industries. It is already the major textile producer in central China and has a wide variety of light manufacturing industries, two railway plants, and one of China's most important arsenals.

Historically, the Wuhan area has been famous as the seedbed of revolutionary movements. In 1911 the revolutionary activity that gave birth to the Chinese Republic erupted among the steelworkers at the Hanyang steelworks, and during the 1920's Hankow was a center of political conflict between the Communists and the Nationalists during the short-lived coalition that was terminated in 1927-1928. More recently, the Wuhan agglomeration was the site of a major reconstruction program to provide public recreational facilities, including parks and "cultural palaces." Of the three cities making up the municipality, Hankow is noted chiefly as a manufacturing and trade center, Wuchang as an educational and administrative center, and Hanyang as a center of heavy industry. Pop. (1958) 2,228,000.

BARUCH BOXER,

Assistant Professor of Geography, Indiana University.

WUHSIEN. See SOOCHOW.

WUHU, wōō'hōō', municipality, China, in southern Anhwei Province. The major industrial and

commercial center of the province. Wuhu is an important Yangtze River port and rail hub, 60 miles southwest of Nanking. Major industries include silk and cotton weaving, egg processing, flour milling, and tanning; rice, cotton, and tea are traded. Wuhu was opened to foreign trade in 1877, and a foreign settlement was established here in 1905. The city was occupied by the Japanese from 1938 to 1945. Pop. (1953) 242,100.

NORTON S. GINSBURG.

WULFENITE, wōōl'fā-nīt, a minor ore of molybdenum, native lead molybdate, PbMoO₄. The best specimens are among the most beautiful minerals known. Wulfenite crystallizes in hemimorphic tetragonal crystals, usually in square tabular plates, sometimes very thin and transparent, but occasionally in elongated pyramidal forms and nearly opaque. The mineral also occurs in crystalline masses. It is very brittle, has a hardness of about 3, and is very heavy, its specific gravity ranging from 6.7 to 7.0. Its luster is resinous to adamantine, and colors are various shades of yellow, orange, red, grayish, or greenish. It is associated with other lead ores at many localities, as in Austria and New South Wales, but the United States localities are far more important. Magnificent specimens occur in the Red Cloud and Mammoth mines of Arizona, in New Mexico, Nevada, and Utah. It was named in honor of the Austrian mineralogist Franz Xaver von Wulfen (1728-1805).

WULFSTAN, wōōl'f'stān, the name of several Anglo-Saxon clerics:

WULFSTAN OF WINCHESTER: fl. 1000. A monk of St. Swithun's, Winchester, he is remembered for his metrical lives of St. Swithun and St. Ethelwold.

WULFSTAN: d. York, England, May 28, 1023. He was archbishop of York from 1003 and bishop of Worcester (1003-1016). He is known for the many homilies attributed to him. The most famous of these is *Lupi sermo ad Anglos*, describing the desperate state of affairs after the Danish raids; it was first printed in 1703-1705 in a translation by George Hickes.

WULFSTAN or **WOLSTAN**, SAINT: b. Long Itchington, Warwickshire, England, c. 1012; d. Worcester, Jan. 18, 1095. Educated at Evesham and Peterborough, he was ordained a priest about 1038 and became a monk in the monastery of Worcester. In 1062, in spite of his objections, he was consecrated bishop of Worcester. He was one of those who submitted to William the Conqueror at Berkhamstead in 1066 and was allowed to retain his see. In 1084-1089 he built a cathedral at Worcester, the crypt of which survives in the present edifice. While not distinguished for extraordinary learning or intellectual attainments, Wulfstan was a man of saintly character and great diligence in his ecclesiastical duties, and is credited with having put a stop to the practice of the merchants of Bristol of selling their fellow citizens into slavery in Ireland. He assisted in the Domesday survey and led the defense of Worcester against the rebellious nobles in 1088. He was the last English bishop to be appointed by a Saxon king and thus formed a link between the old church and the church of Lanfranc and Anselm. He was buried in Worcester Cathedral and canonized in 1203, his day being January 19.

WUNDT, vōōnt, Wilhelm, German and founder of scientific psychology: b. Neckarau, near Mannheim, Germany, Aug. 16, 1832; d. near Leipzig, Aug. 31, 1920. Even in boyhood he studied assiduously and never engaged in play. He earned the degrees of Ph.D. and M.D. at Heidelberg, where for 17 years he was a lecturer in physiology. In 1874 he was appointed professor of philosophy at Leipzig, the university with which his name is most closely associated. There in 1879 he opened the first laboratory of experimental psychology in the world, attracting graduate students from many countries. Among them there were many Americans, who returned from their study with Wundt determined to found similar laboratories, advance the new psychology, and achieve complete independence from philosophy.

The sheer volume of Wundt's publications is amazing. He wrote articles and books on physiology, psychology, and philosophy for nearly seven decades. His first paper, a report on the sodium chloride content of urine, was published in 1853. In 1920 he brought out the 10th and final volume of *Völkerpsychologie* (Folk Psychology). It is estimated that he produced erudite papers and books at the rate of 2.2 printed pages a day. He also encouraged his students to publish research articles, and in 1881 he established the *Philosophische Studien* as a journal for the publication of reports on work done by him and his disciples in the laboratory for experimental psychology and the libraries at Leipzig.

A man of encyclopedic factual knowledge, Wundt sought to identify the elements of consciousness and to state the principles by which these elements are combined. In his studies of the higher mental processes he sought for scientific knowledge through observations of social behavior, particularly of the customs and the language systems prevalent in various ethnic groups. His treatises on philosophy are chiefly an extension of the views he developed in scientific psychology.

PHILIP L. HARRIMAN
Professor of Psychology
Bucknell University

WUOTAN. See ODIN.

WUPATKI NATIONAL MONUMENT, wōō-pāt'kē, a national monument in Arizona, 28 miles north-east of Flagstaff. It was established on Dec. 9, 1924, and embraces about 56 square miles. The monument preserves some 800 archaeological sites which demonstrate remarkably the effect of natural forces on man. Wupatki (Hopi for "tall house") is the principal site in the monument.

Prior to 1064 A.D. Indians in the area lived in single-room pit houses, widely scattered to take advantage of the few places where there was farmland suitable for growing corn, beans, and squash. In 1065 Sunset Crater erupted, driving the inhabitants away and depositing a layer of volcanic ash over an area of 800 square miles. Enterprising individuals soon discovered that this ash acted as a mulch, inhibiting the evaporation of subsurface moisture; thus the volcanic sand made farming possible in an area which today receives an average of only seven inches of rain a year.

New types of housing, especially masonry

pueblos, and pottery indicate that people migrated into the region from all directions, creating an unusual blend of cultural elements. The Citadel, a ruin showing northern affiliation, stands only 50 yards from Nakakihu ("lone house"), whose people apparently came into the area from the south and west. At the height of their prosperity, these people traded for shell from the Gulf of California and the Pacific coast, for copper bells and parrots from Mexico, and for decorated pottery from the Four Corners region. Drought and the removal of volcanic ash by wind erosion drove the inhabitants away by 1300 A.D.

WUPPER RIVER, vōōp'ər, river, Germany, in the State of North Rhine-Westphalia. It is formed at Wipperfürth by various headstreams and flows some 65 miles first northwest and then southwest to empty into the Rhine at Leverkusen between Cologne and Düsseldorf. Although the Wupper follows a tortuous course and does not lend itself to navigation, it provides considerable power for manufacturing purposes, and its valley is densely populated; in it lie the important industrial cities of Wuppertal, Remscheid, and Solingen.

WUPPERTAL, vōōp'ər-tāl, city, Germany, in the State of North Rhine-Westphalia, about 15 miles east of Düsseldorf. It extends for 8 miles along the steep slopes on both sides of the Wupper River, the course of which is followed by the Schwebbahn, a suspended monorail transportation system built in 1901 (see MONORAIL). Wuppertal is an industrial city, its chief products being textiles, including silk, velvet, linen, artificial fibers, carpets, upholstery materials, ribbons, and the like. Iron and steel milling and the manufacture of ball and roller bearings are also important. Other industries include food processing and the manufacture of pharmaceuticals, dyes, firearms, organs and pianos, paper, and leather. Wuppertal is home to a noted clock museum and several colleges for specialized study.

The region about Wuppertal was settled in the 11th and 12th centuries, and numerous communities developed there later. In 1929 the municipalities of Barmen, Elberfeld, Ronsdorf, Beyenburg, Cronenberg, and Vohwinkel were incorporated under the name of Barmen-Elberfeld, and in 1930 the name was changed to Wuppertal.

The famous Elberfeld system of poor relief, later adopted by many other German cities, was instituted here in 1853; under this system, qualified citizens were obliged to serve as almoners to see that the needs of the destitute were taken care of and that every effort was made to channel their abilities into useful activities. Owing to its industrialization, the city was heavily bombed during World War II but has since regained its prosperity. After the war it was included in the Federal Republic of Germany (West Germany). Pop. (1980) 393,381.

WURMSER, vōōrm'zər, **COUNT Dagobert Siegmund von**, Austrian general: b. Strasbourg, France, May 7, 1724; d. Vienna, Austria, Aug. 21, 1797. He served first in the French Army, but left it in 1747 for the Austrian service. In the Seven Years' War he commanded a hussar regiment and attained the rank of major general.

While in command of a special corps in the War of the Bavarian Succession, he distinguished himself at Habelschwerdt (1779). He was again in charge of a corps in the wars of the French Revolution. Defeated at Wissembourg in 1793, he was victorious at Mannheim in 1795. In the following year he was placed in command of the Austrian army opposing Napoleon Bonaparte in Italy. With 45,000 men he compelled the French to raise the siege of Mantua, but defeats at Castiglione, Rovereto, and Bassano made the Austrian situation precarious. Finally Wurmser forced his way into Mantua, whose blockade was resumed. Although another Austrian army was sent to Italy, defeat at Arcole prevented it from relieving him, and on Feb. 2, 1797, Wurmser was obliged to surrender Mantua to Bonaparte.

WÜRTTEMBERG, vŭr'tam-bérkh, former state, Germany, bounded on the northeast and east by Bavaria; on the south by Bavaria, the Lake of Constance (separating it from Switzerland), and the former Prussian Province of Hohenzollern; and on the southwest, west, and northwest by the former State of Baden. It had an area of 7,532 square miles and a population (1939) of 2,907,166. Stuttgart was the capital.

The terrain of the area, which is hilly throughout, includes the Swabian Jura and parts of the Black Forest in the south and west. The Neckar River, canalized from Stuttgart down, connects the center and north with the Rhine Valley. The upper Danube, flowing through the south, is not navigable. The area is not endowed with resources favoring industrial development; nevertheless, while agriculture and forestry have remained important in its economy, its manufactures are prosperous and varied. Among the most important of these are wood, paper, textiles, and metal goods. Leading cities, besides Stuttgart, are Heilbronn, Ulm, Esslingen, Reutlingen, and Göppingen.

History.—The first counts of Württemberg appeared in the 12th century as minor lords of the Duchy of Swabia, then in the hands of the imperial Hohenstaufen dynasty. The fall of this dynasty and the disintegration of Swabia gave the counts the opportunity to acquire substantial possessions in central Swabia in the 14th century. Emperor Maximilian I made Count Eberhard V duke of Württemberg as Eberhard I in 1495. In 1534 the Lutheran Reformation was introduced in the duchy. Duke Christoph (r. 1550–1568) systematically perfected Protestant institutions, creating a much-admired educational system headed by the University of Tübingen, which had been founded in 1477. The duchy suffered terribly in the Thirty Years' War (1618–1648).

The dissolution of the Holy Roman Empire and the reorganization of Germany by Napoleon in 1803–1810 doubled the area of Württemberg, which received the Swabian possessions of Austria, a number of free imperial cities, and many ecclesiastical and secular dominions. Duke Frederick II became elector in 1803 and king as Frederick I in 1806. Through its expansion in the north, Württemberg gained some Franconian territories. Moreover, it lost its exclusively Protestant character by absorbing many Roman Catholics, who have since formed about one third of its population. Nevertheless, it remained essentially a Swabian state, and its cultural unity helped to form a strong state patriotism.

German liberalism developed its greatest strength in southwestern Germany. The grant of

a constitution in Württemberg by King William I (r. 1816–1864) in 1819 did not stifle the liberal and democratic movement, which demanded additional internal reforms and the unification of Germany, and the people of Württemberg played a prominent part in the abortive German revolution of 1848–1849. With the other south German states, Württemberg fought on the side of Austria against Prussia in the Seven Weeks' War of 1866. In November 1870, however, under King Charles I (r. 1864–1891), it agreed to enter the new German Empire, which came into being in January 1871. Within the empire, Württemberg developed its own liberal institutions. In 1906, under King William II (r. 1891–1918), universal, direct, secret, male suffrage was introduced for the second chamber.

In 1919 Württemberg became a republic within the Weimar Republic. The National Socialist regime which came into power in 1933 in effect abolished all the German states, and Württemberg was ruled by a governor appointed by Adolf Hitler. In 1945 northern Württemberg and northern Baden were included in the United States occupation zone as the new state of Württemberg-Baden. Southern Württemberg, Hohenzollern, and southern Baden, forming the states of Württemberg-Hohenzollern and Baden respectively, came under French control. These three rather artificial states became constituent members of the Federal Republic of Germany when it was formed in 1949; but after the removal of occupation controls, a plebiscite was held in the states in December 1951 on a proposal to form a single southwestern state. The merger was approved, and the new State of Baden-Württemberg, with its capital at Stuttgart, was formed in 1952.

HAJO HOLBORN,
Professor of History, Yale University.

WURTZ, vŭrts, **Charles Adolphe**, French chemist: b. Strasbourg, France, Nov. 26, 1817; d. Paris, May 12, 1884. He received a medical degree from the University of Strasbourg in 1843, went to Paris the following year, and in 1845 became assistant to Jean Baptiste Dumas in the Faculty of Medicine at the Sorbonne. He served as professor of chemistry and toxicology there from 1852 to 1875 and also as dean of the Faculty of Medicine (1866–1875). In 1875 he was appointed to the chair of organic chemistry in the Faculty of Sciences and in 1881 was elected a senator. His notable contributions to the advancement of organic chemistry include the discovery of methyl and ethyl amines (1849), glycol (1856), and aldol (1872). The Wurtz column and the Wurtz-Fittig reaction for synthesizing organic halogen compounds are named for him, as is the mineral wurtzite. In addition to the famous *Dictionnaire de chimie pure et appliquée* (3 vols., 1868–78; supplement, 1880), his writings include *Traité élémentaire de chimie médicale* (2 vols., 1864–65), *La théorie atomique* (1878), and *Traité de chimie biologique* (1885).

WURTZITE, wŭrt'sit, a brownish black mineral of composition ZnS (zinc sulfide) that crystallizes in the hexagonal system. Zinc sulfide exists in nature as both sphalerite, α -ZnS, also called blende (q.v.) or zinc blende, and wurtzite, β -ZnS, the latter mineral being the rarer of the two. Significant deposits of wurtzite are found in Missouri and Montana in the United States; Cornwall, England; Bohemia, Czechoslovakia; and France. The

WÜRZBURG

mineral has specific gravity 4.0, hardness 3.5, and good prismatic cleavage. The wurtzite lattice is one of the reference structures for ionic crystals, and as such it has been intensively studied by crystallographers. Wurtzite is named after the French chemist Charles Adolphe Wurtz (q.v.).

KENNETH W. PERKINS.

WÜRZBURG, vürts'boörkh, city, Germany, capital of Lower Franconia in northern Bavaria, on the Main River about 60 miles southeast of Frankfurt am Main. It is a commercial, industrial, and educational center, and a river port. The chief industry is the manufacture of printing machines; there are also breweries and firms engaged in bridge and railroad construction, and wine growing is important in the vicinity. The university (Julius-Maximilians-Universität) evolved in 1582 from a Jesuit college established in 1567, and remained a Jesuit school until 1773; its medical school won fame in 1895 with the discovery of X-rays by Wilhelm Conrad Roentgen. Towering above the city is the Marienberg Castle (1201). Most of the old buildings of the city were destroyed or badly damaged in the air attack of March 16, 1945, which gutted 85 percent of the city, including the Romanesque cathedral (consecrated 1189), the 11th century Neumünster Church, and part of the Residenz (the 312-room bishop's palace built in 1720-1744, one of Europe's foremost baroque structures). The university was heavily damaged but has been reconstructed.

The first documented mention of Würzburg dates from 704. Ruled by its bishops from 741, it developed as a city during the 10th and 11th centuries. The minnesinger Walther von der Vogelweide died here about 1230 and is buried in the cloisters of the Neumünster. The Hohenstaufen emperor Frederick I Barbarossa was married in Würzburg in 1156, and the city was the site of several imperial diets. In 1631, during the Thirty Years' War, the Swedish king Gustavus II Adolphus conquered the city. With the Peace of Lunéville (1801), Würzburg was secularized, and it came under Bavarian control in 1803. In 1805, by the Treaty of Pressburg, it was made an electorate and grand duchy under Ferdinand III of Tuscany, but it was returned to Bavaria in 1815. Following World War II, it was included in the Federal Republic of Germany (West Germany). Pop. (1961) 116,900.

WUSIH or **WU-HSI**, wōō'shē', municipality, China, in southern Kiangsu Province, north of Lake Tai, on the Grand Canal and the Shanghai-Nanking Railway, 26 miles northwest of Soochow. The city is a cotton-, rice-, and flour-milling center; it also has machinery- and needle-manufacturing and oil-pressing industries. It was industrialized during the late 19th century and took over some of the textile-manufacturing functions of Soochow. Previously it had been a walled market town. Pop. (1957) 613,000.

NORTON S. GINSBURG.

WUTHERING HEIGHTS, wūth'ər-īng hits, the only novel by Emily Brontë, published in 1847 under the pseudonym of Ellis Bell (see BRONTË, CHARLOTTE, EMILY, and ANNE). Though almost a complete failure with both the public and the critics, it was reissued in 1849 with an introduction by Emily's more famous sister, Charlotte, author of *Jane Eyre*. *Wuthering Heights* is a be-

lated and unconventional specimen of the so-called Gothic romance or novel of terror, inaugurated by Horace Walpole's *Castle of Otranto* (1764). Its scene is a bleak mansion on the Yorkshire moors, the home of the Earnshaw family, into which the foundling Heathcliff is introduced after being picked up by Mr. Earnshaw on the highroad. The story deals with the fiercely revengeful life of Heathcliff, who develops, under ill usage and neglect, an appalling cruelty, coupled with an inflexible will and a strange power of fascination. He gains control of the Earnshaw property and brings up Hareton, son of the besotted Hindley Earnshaw, whom he hates, in brutal ignorance. The one redeeming trait in his distorted and satanic nature is his wild love for Hindley's sister, Catherine, which outlives both her marriage to Edgar Linton and her death. Thwarted by Catherine's daughter in his endeavor utterly to debase Hareton Earnshaw, Heathcliff starves himself to death, haunted and exhilarated by the spectral presence of the woman who, despite his cruelty (of which she herself felt the effect during her life), has always belonged to him in spirit.

The story is a wild and passionate one, far remote from real life, which Emily Brontë knew scarcely at all. Scenes of domestic violence succeed one another in a way that is almost too much for the reader's nerves. The characters are the creation of a lawless but extraordinarily vivid imagination, and the whole novel is written with an energy that triumphs over the obvious limitations of its author's art.

JAMES H. HANFORD

WUTUNGKIAO or **WU-T'UNG-CH'IAO**, wōō' tōōng'chyou', municipality, China, in south central Szechwan Province, on the east bank of the Min River, 15 miles southeast of Loshan. It is a center of salt production. Pop. (1953) 199,100.

NORTON S. GINSBURG.

WYANDOT INDIANS, wī'an-dōt, or **HURON INDIANS**, hūr'ōn, a confederation of North American Indian tribes. The name Huron is an Old French word meaning "a person with bristly unkempt hair" and was first given to the confederation by the French in the early 17th century. The Indians called themselves Gendat o Wendat (Wyandot), signifying "island or peninsula dwellers." A loose confederacy of Iroquoian speaking tribes, they occupied in 1615 the territory known as Huronia, with villages concentrated at the southern end of Georgian Bay and Lake Simcoe in what is now Ontario, Canada. Father Jean de Brébeuf said that they had 20 villages and a total population of 30,000, which included the Bear people (Attignauquantan), Cord people (Attigeenongnahac), Rock people (Arendahronon), and Deer people (Tohontaenrat). An agricultural people with social, political and ceremonial institutions similar to those of the Iroquois, the Huron-Wyandot grew by adopting whole populations. They allied themselves early with the French against the Iroquois League (q.v.). The Iroquois wars, smallpox, and other communicable diseases introduced by the white man destroyed their confederacy by 1650. Several hundred survivors who wintered at Quebec (1649) were given refuge by the Fi In 1693 Father Pierre Joseph Marie Chau built a chapel near Quebec dedicated to Santa Casa of Loreto, Italy; the descendants

re Huron survivors living in Loretteville near his chapel have since been known as the Huron of Lorette. Most of the other Huron were adopted by members of the Iroquois League, and in 1653 Father Simon Le Moine said that there were more than 1,000 Christian Huron living with the Onondaga.

The Huron who sought refuge with the Erie shared their defeat (1653-1656) and were adopted by the league members or dispersed. Some of those given refuge by the Tionontati (Tobacco) escaped the wrath of the Iroquois by fleeing westward. After suffering many hardships in Michigan and Wisconsin, they were befriended by the Potawatomi and the Ottawa and allowed to settle among them. Fathers Claude Allouez (1665) and Jacques Marquette (1669) noted the vicissitudes and wanderings of these Huron, who became known as Wyandot. During the 18th century most of them had moved to the vicinity of what is now Sandusky, Ohio, and after the peace of 1815 land in Ohio and Michigan was granted them by the United States. In 1819, however, they sold all their land except the territory near the upper Sandusky River and a small section near Detroit, where they lived until they moved to Kansas in 1843. The treaty of 1855 conferred citizenship on them but resulted in forced land sales. In 1859 the Seneca-Cayuga gave the homeless Wyandot 13,000 acres of their reservation in Oklahoma, reciprocating the hospitality which the Wyandot had extended in 1817 when the Seneca-Cayuga were themselves homeless. The agreement between the tribes was confirmed by a treaty with the United States in 1867, whereby the Wyandot received 20,000 acres. In 1871 the Wyandot tribal organization was restored, and they were placed under the jurisdiction of the Quapaw Agency, Oklahoma. In the mid-1950's the Huron-Wyandot in Oklahoma numbered approximately 894; those in Quebec, about 800.

See also IROQUOIS INDIANS.

GEORGE S. SNYDERMAN.

WYANDOTTE, wī'an-dōt, city, Michigan, in Wayne County, on the Detroit River, 11 miles southwest of Detroit. It is an industrial center noted especially for its chemical products, which are derived from the vast salt beds underlying the area. Some of the products manufactured are chlorine gas, dry ice, soda ash, plastics, spark plugs, paint, automobile parts, brass fittings, metal wheels, cleaning compounds, dairy products, and beverages. From 1872 until 1920 Wyandotte was a major shipbuilding center for the Great Lakes. Iron manufacturing developed here in the mid-1850's, and a blast furnace constructed in 1864 produced the first commercial Bessemer steel in the United States. The city is named after the Wyandot Indians, from whom the area was obtained in 1818. It was incorporated as a city in 1867. Government is by mayor and council. Population: 30,938.

EDWINA DEWINDT.

WYANDOTTE CAVE, a natural limestone cavern in Indiana, situated in Crawford County, 25 miles west of New Albany. Discovered in 1798, it was used as a source of saltpeter until 1850, when it was opened to the public. Its 5 levels have been explored for 23 miles. Some of its chambers are 350 feet long and 180 feet high. Places of interest include Monument Mountain, 175 feet high, and

the Pillar of the Constitution, a stalagmite 75 feet in circumference.

WYANT, wī'ant, **Alexander Helwig**, American landscape painter: b. Evans Creek, Ohio, Jan. 11, 1836; d. New York, N.Y., Nov. 29, 1892. In his youth he was apprenticed to a harness maker, but in 1857 he saw some paintings by George Inness and decided to become an artist. With assistance from Nicholas Longworth and others, he studied in New York City and in Europe, where he became a pupil of Hans Gude at Karlsruhe in 1865. He first exhibited at the National Academy of Design, New York City, in 1864 and was elected to membership in 1869. While he maintained a studio in New York, he spent his summers in the Adirondack and Catskill mountains, and he is best known as a painter of poetic scenes of woods and valleys. His mature landscapes are distinguished by their subtle coloring and portrayal of light and shadow under changing skies. Among his works are *In the Adirondacks*, *The Mohawk Valley*, and *Clearing After Rain*, Metropolitan Museum of Art, New York City; *The Connecticut Valley and Landscape*, Corcoran Gallery of Art, Washington; *Passing Clouds and Moonlight and Frost*, Brooklyn Museum; and *In the Still Forest*, Worcester Art Museum.

WYATT, wī'at, **Sir Francis**, British colonial governor in America: b. Kent, England, 1588; buried Boxley, Kent, Aug. 24, 1644. The great-grandson of the poet Sir Thomas Wyatt (q.v.), he was married in 1618 to a niece of Sir Edwin Sandys. Through this connection he became in 1620 an investor in the Virginia Company and in the following year was chosen governor of Virginia. He arrived in the colony in October 1621, bringing with him a new constitution. His term of office was marred by the Indian massacre of 1622, but he was a successful and popular administrator. After the company was dissolved in 1624, he served as the first royal governor until 1626, and is remembered especially for his ultimately successful effort to preserve representative government in the colony. He was governor of the colony again in 1639-1641.

WYATT, **James**, English architect: b. Burton Constable, Staffordshire, England, Aug. 3, 1746; d. near Marlborough, Wiltshire, Sept. 4, 1813. He was taken to Rome about 1760 by the 1st Baron Bagot, and for the next six years studied architecture there and in Venice. Returning to England in 1766, he attracted notice with his designs for the Pantheon (1772), a fashionable London meeting place until its destruction by fire in 1792. In 1796 he was appointed surveyor general to the Board of Works. Besides numerous private commissions, of which the most famous was the neo-Gothic Fonthill Abbey (1795), he designed the Royal Military Academy, Woolwich (1796) and did much work for George III at Windsor. About 1782 he abandoned the Graeco-Italian style of his early buildings for the Gothic, which he was one of the first architects to revive. Because of the ruthlessness with which he removed Renaissance additions in restoring Salisbury, Lincoln, Hereford, and other cathedrals, he was called "the Destroyer," but this view of his work is not justified.

WYATT, **Sir Thomas**, English poet: b. Allington Castle, Kent, England, 1503; d. Sherborne, Dorset,

Oct. 11, 1542. Evidence that he received an M.A. degree at Cambridge has been disproved. He married Baron Cobham's daughter, Elizabeth Brooke, who became the mother of his son Thomas (see WYATT, SIR THOMAS, 1521?-1554) and a daughter. Already known at the court of Henry VIII, he found employment there, participated in the Christmas 1525 tournament before the king, and the following year served on a diplomatic mission to France. In 1527 he was sent to Italy, where the Spanish captured and held him for ransom, but he managed his own escape. The next few years he was marshal of Calais. He returned to England, became commissioner of the peace for Essex, and in 1533 officiated at the marriage of Henry VIII and Anne Boleyn, whom he may have known most of his life and whose lover he was reputed to be. He lived only a few years with his wife, who had been unfaithful.

Wyatt had great intellectual gifts, but there is evidence that he was restless and impetuous. He was imprisoned briefly in 1534 and again in 1536, the latter instance involving differences with Charles Brandon, duke of Suffolk. Popular opinion has built a tradition that he continued intimate relations with Anne after she became queen and was implicated in her downfall in 1536, but evidence is lacking. He had probably been knighted the previous year, but the king made him sheriff of Kent a few months later and the next spring appointed him ambassador to Spain. He served on a special mission to France and the Netherlands in 1539, returning to witness the execution of his friend and protector Thomas Cromwell in July 1540. His enemies plotted his downfall the following January on charges of treason, but his usual honesty, courage, and eloquence prevailed. His dramatic defense was circulated in manuscript and discomfited his accusers. New honors were bestowed upon Wyatt, and he was on a special mission to Falmouth to escort Spanish envoys when he caught fever and died.

Wyatt was the first of the great Tudor poets who, within the span of a single century, elevated English verse from obscurity to the first ranks of world literature. Like Chaucer he probably came in direct contact with French and Italian poets through diplomatic service, and he introduced new verse forms into English. Much of his experimental verse is translated or adapted from foreign sources, particularly Italian, but most of his best poems are original and some of them deeply personal. He introduced and popularized the sonnet in English and wrote a few excellent rondeaus and epigrams such as *What No, Perdie*; *Tagus, Farewell*; and *Lux, My Fair Falcon*. Using *terza rima* as a new English verse form adapted from the Italian, he wrote three satires and seven penitential psalms which were widely acclaimed, but it was in the simple and more native tradition of the song form that he found enduring greatness as a poet. *Forget Not Yet*; *Blame Not My Lute*; *My Lute, Awake*; and *In Eternum* represent Wyatt at his best.

His sonnets contain Petrarchan conceits characteristic of the Elizabethans, but not their mellifluous meters; yet most of his songs have the simple sincerity and rhythmic skill of the lover and musician that legend has made him. A deeply serious nature is revealed in the satires and psalms and in the prose of two letters to his son and the defense prepared for his trial. The poet and the man become inseparable, for like Sir Philip Sidney he seemed a fulfillment of the Renaissance ideal—

soldier and statesman, courtier and lover, scholar and poet.

Most of Wyatt's poems were preserved in manuscript collections. *Certainne Psalmes* was published in 1549 by Thomas Raynald and John Harrington, and 97 poems attributed to him were printed in Tottel's miscellany entitled *Songs and Sonnets* (1557).

WILLIAM BRACY,
Humanities Editor, "The Encyclopedia Americana."

WYATT, SIR THOMAS (called **THE YOUNGER**), English soldier: b. ?1521; d. London, England, April 11, 1554. Son of the poet and diplomat Sir Thomas Wyatt (q.v.), he served with the English Army in France from 1543 to 1550. In 1554 Edward Courtenay, earl of Devonshire, invited him to help raise a general insurrection to prevent the marriage of Mary I with the future King Philip II of Spain. Wyatt alone avoided arrest and marched on London with some 4,000 men in what came to be known as Wyatt's Rebellion. His army melted, however, before the queen's forces, and Wyatt was taken prisoner. He could offer no defense at his trial and was beheaded for treason. On the scaffold he exonerated the future Elizabeth I, whom Mary's supporters had hoped to implicate in the conspiracy.

WYCHERLEY, wích'ar-lē, **William**, English dramatist: b. Clive, Shropshire, England, May 28, 1641, d. London, Jan. 1, 1716. At the age of 15 he was sent to France to be educated, but spent his time in the salon of the duchesse de Montausier, daughter of the famous marquise de Rambouillet, learning foppish habits. He also became a Roman Catholic. When he returned to England, his father sent him to Queen's College, Oxford, to undo the French education, but Wycherley left the university in 1659, without having earned a degree, and went to London, where he entered the Inner Temple to study law.

The fashionable world of London proved more attractive to Wycherley than his law studies, and by 1671 he had written his first comedy, *Love in a Wood, or St. James's Park*. It earned him the attention of the court wits and introduced him to a life of excitement which only death would still. He became the lover of Charles II's mistress, Barbara Villiers, duchess of Cleveland, and in 1680 married the beautiful widowed countess of Drogheda, who died soon after, leaving him a fortune which he lost in lawsuits over the inheritance. He then spent three years in debtor's prison until James II paid his debts and gave him an annual pension, which was withdrawn at the Revolution of 1688. Wycherley inherited his father's estate in 1689 but was forbidden by entail to sell any of it. Finally, 11 days before his death, and at the age of 75, he married a young woman, Elizabeth Jackson, at the insistence of his cousin Thomas Shrimpton, who married the young widow very soon afterward in order to share the inheritance from Wycherley's estate that she had received on Wycherley's death.

Wycherley's development as a dramatist showed a steady advance. His first comedy had no central theme, but his second, *The Gentleman Dancing-Master* (1672), satirizes the "masquerading Age" which saw reality as pretense and pretense as reality. His third comedy, *The Country Wife* (1675), is his masterpiece, and to many readers it is the best of the great come-

lies of the Restoration. The play again satirizes false appearances, but at the same time it presents an ideal way of life not subjected to satire. In 1676 Wycherley's last and most profound comedy was produced, *The Plain-Dealer*, based upon Molière's *Le misanthrope*. Manly, the protagonist, dupes himself as his rage for sincerity drives him to search for the ideal in a world of pretense and corruption. The play transcends its immediate period and attains the level of universal satire.

DONALD B. CLARK
Professor of English, University of Missouri

WYCKOFF, wī'kōf, township, New Jersey, in northwest Bergen County, 10 miles by road north of Paterson. The name is derived from the Indian *wikhoff*, meaning "high ground." The township is predominantly residential, with the majority of the working population commuting to nearby metropolitan centers, such as Paterson and New York.

The first inhabitants of the area were Leni-Lenape Indians. Dutch settlers from New York City established a farming community on that location in 1720, and the township still bears the imprint of these early residents in the architecture of its oldest houses, many of which have been continuously occupied for over two centuries. The Wyckoff Reformed Church, built in 1806, is one of the oldest in New Jersey.

The present township was originally part of a larger tract incorporated in 1771 as Franklin Township, which in 1922 was divided into smaller parcels, one of them taking its name from the village of Wyckoff. The government is conducted by a committee of five members, of whom the chairman holds the honorary title of mayor. Pop. 15,500.

WILLA BUSSOM

WYCLIFFE, wīk'lif (also WICLIF, WYCLIF, or WICKLIFFE), John, English religious reformer: b. near Richmond, Yorkshire, England, c. 1320; d. Lutterworth, Leicestershire, Dec. 31, 1384. Member of an old Yorkshire family, he entered Balliol College, Oxford, in 1344 and later (sometime between 1356 and 1360) became its master. Although his first inclination was scientific and philosophical, he also studied theology and canon law, as well as local history. From 1365 to 1367 he was warden of Canterbury Hall in Oxford, a duty he presumably performed in addition to his duties at Balliol. He became a doctor of theology in 1372. His lectures were popular and well attended, and he was widely known for his gift as a preacher. In 1374, by favor of the king, he became rector of Lutterworth, a position he held for the rest of his life; meanwhile, he continued lecturing at the university.

Ecclesiastical Reform.—Also in 1374 Wycliffe was one of the royal envoys sent to confer with papal representatives at Bruges on the subject of provisions—papal appointments to ecclesiastical posts before they became vacant. Perhaps in part as a result of this experience, he became involved (in 1376) in the movement that sought to achieve ecclesiastical reform. At least it appears that his political, not his theological, views led him to oppose and to criticize the papal system, especially its methods of appointments, fees, and taxation.

The Good Parliament of 1376 was already endeavoring to correct ecclesiastical abuses. Wycliffe's

views at this time were far from radical, but gradually he became convinced, largely by his Biblical studies, that the church was not what it should be, and that it must be brought back to apostolic purity of life and doctrine. The possession of secular power by the clergy was incompatible with true religion and the teaching of the Saviour. The conclusion that papal control of the English church and its financial levies must end was only one of the inferences that he began to draw from this newly adopted principle. Protected by his patron, John of Gaunt, duke of Lancaster, he now issued a series of pamphlets which advocated, among other things, the position that it was the duty of the state to intervene and take control of the church's properties in the interest and benefit of the poor. (Many of the church's endowments had been bequeathed for that specific purpose.)

Both the nobility and the middle class readily accepted this principle, but the bishops and the well-endowed religious orders vigorously objected. Wycliffe was cited to appear before the bishop of London on Feb. 19, 1377. He was accompanied by a group of mendicant monks who promptly rioted, and the meeting came to nothing. Meanwhile, the pope, Gregory XI, issued 5 bulls condemning 18 of Wycliffe's "conclusions" and summoned him to appear before a papal court; but neither the government nor Oxford University was willing to hand him over to an ecclesiastical trial. His enemies hoped that he would become entangled in political toils, but Wycliffe had the support of members of the royal family; moreover, the king, Edward III, died that year. The following year (1378), Wycliffe was summoned to Lambeth Palace in London to make an appearance before the archbishop of Canterbury. The result was another tumult. As a consequence, Wycliffe summarized his teaching in 33 statements and prepared himself to defend his controversial views at Rome, but before he could set out on the journey, the pope died.

Translation of the Bible.—Wycliffe now began writing about "the Law of God," by which he meant the Bible, as distinguished from papal pronouncements and traditions. He inferred that the true church is one and indivisible, with Christ as its only Head, not the pope; the Babylonian captivity of the popes at Avignon (1309–1377) had undermined popular confidence in papal authority. The true apostolic church, he held, is not to be identified with the visible institution, but is made up of the elect, who have been predestined to be its members. Salvation depends upon predestination and grace rather than upon baptism and membership in the visible church. Another inference was "the priesthood of all believers" rather than the succession of validly ordained ministers. Royal power derives from God, for the purpose of protecting the weak and administering justice, and must be accounted for on the Last Day. Hence the clergy must obey the law of the land and the orders of the sovereign: the king is their superior in all civil matters, and they hold their "temporalities" by his consent. Even the pope cannot dispense from this rule. The pope deserves reverence only when he lives and acts in a Christlike manner—the church can exist without him. As the Bible is the Christian's law, it must be made known in the vernacular. Wycliffe began the first complete translation into English, a task in which he had the help of Nicholas Hereford and John Purvey. He also sent out itinerant

preachers ("poor priests," that is, seculars, not mendicants or regulars), who were to live among the people and preach the Gospel, not as rivals of the parish clergy but as supplementers of their work. Most of these preachers were Oxford men.

Forerunner of the Reformation.—Eventually, Wycliffe attacked transubstantiation (q.v.), and his sacramental teaching was denounced by the Oxford authorities in 1381 as heretical. Wycliffe appealed not to the pope, but to the king. That year saw the Peasants' Revolt and a consequent reaction among all conservatives in church and state against radical views such as those of Wycliffe. The mendicants turned against him, and the Earthquake Synod (so called because an earthquake took place during its sessions) in London called upon the state to extirpate the false teaching. But the House of Commons refused to act. In his teaching, Wycliffe had condemned auricular confession, absolution, confirmation, orders, unction, celibacy, the "power of the keys," veneration of statues and relics, invocation of saints, pilgrimages, masses for the dead, the doctrine of purgatory, and other traditional teachings and practices of the church. This earned for him the later title of Morning Star of the Reformation, and his influence is clearly to be traced in Jan Hus and others all the way to Martin Luther and John Calvin. Even more important was the power he attributed to the state in its relation to the church, and his view of predestination and the invisible nature of the true church.

Modern scholars tend to emphasize the importance of the social and political background of Wycliffe's views. He shared the 14th century reaction against tradition and the increasing nationalism and secularism of the time. Such thinkers as Marsilius of Padua and William of Ockham had prepared the way for his political and ecclesiastical views. Wycliffe was a staunch follower of Thomas Aquinas but was influenced by later trends. Lordship, he held, was distinguished from possession, as a stewardship under God. Property is the result of sin: Christ and the apostles had none. Wicked men are not entitled to property, and the state must see that they are deprived of it: the clergy and monks must be compelled to live in apostolic poverty. At the same time, Wycliffe was a loyal supporter of the secular power, since human affairs are guided by divine providence (compare Romans 13:1). The church has no concern with temporal affairs. It is strange that Wycliffe was surprised to find his teaching echoed far and wide, and that "every sparrow twittered about it."

WYE RIVER, wī, river, Wales and England, about 135 miles long. It rises on the slopes of Plynlimon (2,468 feet) in west-central Wales, flows south-east past Rhayader and Builth Wells, and enters England at Hay. It then turns eastward to Hereford, whence its course is southward by Ross and Monmouth to Chepstow, 2½ miles beyond which it enters the estuary of the Severn. Its principal tributaries are the Elan, Ithon, Yrfon, Lugg, and Monnow.

The Wye is distinguished for the variety and beauty of its scenery, particularly in its lower reaches, two noteworthy points being the ruined Tintern Abbey (q.v.) and the extraordinary loop between wooded hills at Symond's Yat. Boating is possible over short stretches of the river at Hereford, Ross, Monmouth, and Chepstow, but in general is prohibited by weirs, rocks, and a fast current. The effect of the Severn tide (which rises 46 feet at spring tides) is felt as far as Bigsweir, 9 miles above Chepstow.

H. GORDON STOKES.

WYETH, wī'əth, Andrew (1917–), American painter, who is probably the best known, and certainly the most beloved 20th century American artist. In the sense that he belongs to no group or school and has worked far from the centers of artistic activity, Wyeth is a solitary, but in tastes, tradition, and training he is completely American. Wyeth finds his subject matter entirely in the two regions in which he lives—the rural countryside of his winter home at Chadds Ford, Pa., and the seashore, islands, and bleak houses around Cushing, Me., where he spends his summers. Because of their familiarity, the simple, often somber landscapes and the unpretentious spare people of his paintings appeal immediately. At first glance he seems to have recorded with precise accuracy. Actually, however, every composition is transformed by a pervasive poetic vision that tempers exactitude without deforming either the subject or the setting.

The subtle symbolism of Wyeth's paintings and its quiet import are revealed only on slow examination. Modest in scale, reflective in theme, admirable in craftsmanship, Wyeth's work speaks of universal experience. The people he depicts are self-contained and self-sustaining. Their austere world is recorded in browns, russets, tans, and deep greens that are almost black, enlivened by touches of bright geranium red or clear, light blue. Fields and forests, sky, wind, and the sea, the hunter and the hunted, life and death and life again—these are Wyeth's themes.

Early Life.—Andrew Wyeth was born on July 12, 1917, in Chadds Ford, Pa., the youngest of the five children of the well-known artist and illustrator Newell Convers Wyeth (q.v.). Because he was not of robust health, Andrew was educated at home by his parents. He received his art instruction from his gifted father, who gave him a thorough grounding in anatomy, trained his powers of observation, and disciplined his visual memory. Among his earliest works are some pen-and-ink drawings made at the age of 12 for a book illustrated by his father. Some of Wyeth's Negro neighbors of Chadds Ford, Pa.

Christina's World (1948) is one of Andrew Wyeth's best-known works.

Collection, The Museum of Modern Art, N.Y.

miliar figures in his adult paintings, first appeared in his earliest watercolor drawings.

Between 1924 and 1926 the New Mexico artist Peter Hurd studied with Andrew Wyeth's father, and it was Hurd who taught young Wyeth the demanding tempera technique. At 16, Wyeth first saw the work of Winslow Homer and discovered a kindred spirit. At the age of 20 he had his first one-man show, entirely of watercolors, at the Macbeth Gallery in New York, and every painting was sold. If there seemed to be some influence of Winslow Homer in the choice of outdoor subjects, each watercolor was authentically personal in its tonality and in its transcription of air and light. Although Wyeth continued to make watercolors and what he called "dry brush drawings," he gradually turned more and more to tempera for his paintings.

Mature Paintings.—Andrew Wyeth's father was killed in 1945 in a car accident, and his first tempera after this sad event was a turning point for the artist. *Winter 1946* (1946; private collection, Cambridge, Mass.) is a picture filled with haunting overtones. It represents a young boy, dressed in a World War II uniform, running down a barren hill edged by traces of snow, his long thin shadow beside him. The picture is filled with a sense of sadness and of loneliness.

Often an event in daily life, sharpened by a sudden revelation of private heartache, gives Wyeth a subject for a painting. Through sketches and drybrush drawings he works out the composition, and it was in this way that Wyeth's best-known painting, *Christina's World* (1948; Museum of Modern Art, New York) came into being. Wyeth saw his neighbor, Christina Olson, a woman crippled by poliomyelitis, picking berries in the grass near her family burying ground. She paused to look up to the family home on the hill, a large empty-looking house. One need know nothing of Christina to feel the drama that haunts the scene.

In *Distant Thunder* (1961; private collection, New York), only the dog is alert to the rumbling of the coming storm, the berry picker sleeps gently on. The title, brilliantly chosen for this particular painting, could also serve symbolically for many others. Even in Wyeth's most quiet scenes, a similar ominous force is often suggested—by great boots tramping, hawks circling

slowly above barren hills, empty milk pails up-ended, quiet fog rolling in from the sea, a stiff dead deer swinging in the winter wind, or an empty rocking chair in a lovely landscape.

The so-called Helga Pictures, 240 drawings and paintings of a neighbor of Wyeth, date from the years 1971–1985. They were revealed to the public in 1986.

AGNES MONGAN*, *Fogg Art Museum*

WYETH, Newell Convers, American painter and illustrator: b. Needham, Mass., Oct. 22, 1882; d. near Chadds Ford, Pa., Oct. 19, 1945. After studying art in Boston, he went to Chadds Ford, Pa., to study with the illustrator Howard Pyle. Wyeth became one of America's most noted illustrators, achieving an even wider reputation than his teacher. Among some 20 juvenile classics that he illustrated are *Treasure Island* and other books by Robert Louis Stevenson, adventures of Robin Hood and King Arthur and his knights, Jane Porter's *The Scottish Chiefs*, James Boyd's *Drums*, and Marjorie K. Rawlings' best seller, *The Yearling* (1939 edition).

Wyeth was equally active as a mural painter and executed commissions for hotels, banks, churches, and other buildings. These include Civil War battle scenes for the Missouri State Capitol; a triptych for the Hotel Roosevelt and panels for other buildings in New York City; and murals in Boston, Washington, and other Eastern cities. He also painted scenes from country life in egg tempera. Among his numerous pupils were his son Andrew Wyeth (q.v.), his daughter Henriette, and Peter Hurd, who became a son-in-law.

FREDERICK A. SWEET.

WYKEHAM, William of. See WILLIAM OF WYKEHAM.

WYLD, wild, Henry Cecil Kennedy, English philologist and lexicographer: b. London, England, March 27, 1870; d. Alvescot, Oxfordshire, Jan. 26, 1945. Educated at Bonn, Heidelberg, and Oxford universities, he became first Baines professor of English language and philology at the University of Liverpool in 1913, was Merton professor of English language and literature at Oxford from 1920 until his death. His

studies in English phonetics, philology, and historical grammar had great influence. Besides many papers, he published *The Study of Living Popular Dialects and Its Place in the Modern Science of Language* (1904); *The Growth of English* (1907); *A Short History of English* (1914; 3d ed., 1927); *A History of Modern Colloquial English* (1920; 3d ed., 1936); and *Studies in English Rhymes* (1923). His work as editor of *The Universal Dictionary of the English Language* (1932) was distinguished for its complete etymologies and original illustrative sentences.

WYLIE, wīlĕ, Elinor Morton (née Hoyt), American poet and novelist: b. Somerville, N.J., Sept. 7, 1885; d. New York, N.Y., Dec. 16, 1928. She was educated at the Baldwin School, Bryn Mawr, Pa., and the Holton Arms School, Washington, D.C., and in 1905 married Philip Hichborn. In 1910 she eloped with Horace Wylie, to whom she was married in 1916. The Wylies were divorced in 1923, and she then married William Rose Benét (q.v.), the poet and critic.

Elinor Wylie

Alfred A. Knopf

Elinor Wylie's work consists in the main of eight books—four novels and four volumes of verse—in which she made wide use of the lore of history and literature. Well acquainted with Scotch, Irish, and English ballads, she liked to sing them, as well as her own verses, which she set to tunes that she made up herself. Her first novel, *Jennifer Lorn* (1923), was immediately recognized as possessing a rare and delicate satire, particularly of those qualities in men that make them attractive to women and at the same time objects of raillery. *The Venetian Glass Nephew* (1925) is a fable of the marriage of Christian art and pagan nature. *The Orphan Angel* (1926) relates the fantasy that the poet Percy Bysshe Shelley was rescued by an American ship instead of drowning. Shelley's subsequent adventures on the rough American frontier give Mrs. Wylie scope for witty and sensitive analysis of both the poet and the times. In *Mr. Hodge and Mr. Hazard* (1928), she deals with the England that has rejected Shelley, turning her irony upon the historical roots of contemporary mores.

In her verse, which includes *Nets to Catch the Wind* (1921), *Black Armour* (1923), *Trivial Death* (1928), and the posthumous *Angels and Earthly Creatures* (1929), Elinor Wylie is an extraordinarily refined artist and shows the influence of the ballad writers, the Elizabethans, and the metaphysical poets. Perhaps her favorite sub-

ject is the reality that underlies convention. In *Beauty*, for example, she writes of a quality that is neither good nor wicked:

O, she is neither good nor bad,
But innocent and wild!
Enshrine her and she dies, who had
The hard heart of a child.

More specifically, she often deals with her own personality as it is, rather than as others define it; or she punctures grandiose and glib formulations.

JOHN ASHWORTH,
Lecturer on Writing, Columbia University.

WYLIE, I(da) A(lexa) R(oss), British author: b. Melbourne, Australia, March 16, 1885; d. Princeton, N.J., Nov. 4, 1959. Soon after she was born, her family moved to England, and her mother died. From her 10th year, her father gave her money to travel unaccompanied through Europe, and until the age of 14 she received no formal education, although she read avidly. By this time she had decided to become an author. After attending schools in Belgium and England, she went to Germany at 19 for further education, remaining 8 years and writing her first published stories. In 1911 she became active in the suffrage movement in England, and in 1917 she visited the United States, where she spent her later years. She never married.

Miss Wylie's fiction frequently deals with themes of political and social import, and her travels provided her with insights into national as well as individual character. *Towards Morning* (1920), her first mature novel, was an outgrowth of her residence in Germany, and *To the Vanquished* (1934) takes place under the rise of Nazism. After a visit to the USSR in 1934, she wrote *Furious Young Man* (1935); its protagonist is a young English convert to communism. *Where No Birds Sing* (1947) is set in Germany under the American occupation. *Candles for Therese* (1951) is about a man's quest for revenge on the betrayer of some resistance fighters during World War II. In *The Undeclared* (1957), her last novel, Miss Wylie's theme is the effort made by members of a guilt-ridden community in postoccupation Provence to exculpate themselves. She also wrote more than 200 short stories, some screen plays, and an amusing autobiography, *My Life with George* (1940), George being her unconscious mind.

WYLIE, Philip, American writer: b. Beverly, Mass., May 12, 1902; d. Miami, Fla., Oct. 25, 1971. After spending three years at Princeton University and two years on the *New Yorker* staff, he began a free-lance career writing popular fiction. He was in Hollywood as a script writer for Paramount Pictures (1931-1933) and Metro-Goldwyn-Mayer (1936-1937) and marketed reams of stories and articles in popular magazines such as *Red Book* and the *Saturday Evening Post*. His first novel was *Heavy Laden* (1928) and his last was *The End of the Dream*, published posthumously in 1972. He also wrote science fiction volumes (1932-1936) in collaboration with Edwin Balmer, editor of *Red Book Magazine*; *The Army Way* (1940), in collaboration with William W. Muir; and some anonymous writing.

A special interest in the study of psychology, particularly the work of Carl Jung, motivated Wylie's most successful books: *A Generation of Vipers* (1942), vituperative essays on "mormonism"

and other American ills; *Essay on Morals* (1947) earnest but iconoclastic; and the novel *Opus 21* which attempts, along with pessimism and ribaldry, an analysis of ills in American society. Some of his later volumes are collections of fishing stories based on the adventures of his popular characters Crunch and Des.

WILLIAM BRACY.

WYMAN, wī'mən, **Horace**, American inventor: b. Woburn, Mass., Nov. 27, 1827; d. Princeton, Mass., May 8, 1915. After working for some 15 years as a machinist and draftsman, he became superintendent of the Crompton Loom Works, in Worcester, Mass., soon after 1860 and took out the first of his more than 200 loom and textile machinery patents in 1867. He served as manager of the Crompton firm from 1886 until 1897, when it merged with the company founded by Lucius James Knowles; he then continued with the new Crompton & Knowles Loom Works as vice president and consulting engineer until his death. Wyman did considerable work on box motions, particularly for gingham looms, and laid the groundwork for the application of the bobbin-changing principle to fancy or box looms.

WYMAN, Jeffries, American anatomist and ethnologist: b. Chelmsford, Mass., Aug. 11, 1814; d. Bethlehem, N.H., Sept. 4, 1874. He graduated from Harvard College in 1833 and from Harvard Medical School in 1837. After practicing medicine in Boston, he taught anatomy and physiology at Hampden-Sydney College in Virginia (1843-1847) and from 1847 until his death served as Hersey professor of anatomy at Harvard. There he established the Museum of Comparative Zoology, which he did much to expand, and also served (1866-1874) as the first curator of the Peabody Museum of Archaeology and Ethnology. From observations made in New England and on trips to Labrador (1849), Florida (1851-1852), Surinam (1856), and various parts of South America (1858), he acquired much of the information he presented in more than 175 scientific papers. Among these were *Anatomy of the Nervous System of Rana Piptiens* (1853); *An Account of Some of the Kjoekkenmoeddings, or Shell-Heaps, in Maine and Massachusetts* (1867); *Observations and Experiments on Living Organisms in Heated Water* (1867); *Observations on Crania* (1868); and *Fresh Water Shell Mounds of the St. John's River, Florida* (1875).

WYNANTS or **WIJNANTS**, vī'nānts, **Jan**, Dutch painter: b. Haarlem, the Netherlands, 1630/1635; d. Amsterdam, buried Jan. 23, 1684. Aside from the fact that he was the master of Adriaen van de Velde and collaborated with Philips Wouwerman, and other painters, little is known of his life, but he produced at least 700 canvases. Most of them are small, highly detailed landscapes, often of dune or forest scenes, in which the human figures and animals are frequently the work of his pupils or collaborators. His paintings are found in all the major European galleries.

WYNDHAM, wīn'dəm, **SIR Charles** (original surname **CULVERWELL**), English actor-manager: b. Liverpool, England, March 23, 1837; d. London, Jan. 12, 1919. Like his father, he became a surgeon but by 1862 was acting on the professional stage after establishing a brilliant amateur record. During the Civil War in the United States he

served as a surgeon in the Union Army and also acted in New York City. With his own company he returned to America (1869-1871), where he emerged as an adroit light comedian. His success in Brighton (1874) convinced English audiences that Charles Mathews' successor had been found. From 1876 he was the lessee of the Criterion Theatre and subsequently opened Wyndham's (1899) and the New (1903) to round out his theatrical empire, which he ran intelligently and profitably with Mary Moore (1861-1931), his leading lady, who became his second wife in 1916. In later years he also excelled in serious roles, notably in Henry Arthur Jones' last good play, *Mrs. Dane's Defence* (1900). He was most applauded in the name role of T. W. Robertson's *David Garrick* (1886). He was knighted in 1902. His last New York appearance was in 1910.

WALLACE BROCKWAY.

WYNN, wīn, **Ed** (original name **ISAIAH EDWIN LEOPOLD**), American entertainer: b. Philadelphia, Pa., Nov. 9, 1886; d. Beverly Hills, Calif., June 19, 1966. By the age of 19 he was a leading Broadway vaudeville performer, and later he was featured in the Ziegfeld *Follies* of 1914 and 1915 and other productions. During the 1920's he appeared in a series of successful Broadway musical shows, producing and writing the music and words for such hits as *Ed Wynn's Carnival* (1920) and *The Perfect Fool* (1921). In 1932 he began a popular radio program as the Texaco Fire Chief, and he returned to Broadway with great acclaim in *Boys and Girls Together* (1940).

Wynn was in his seventies when he started a new career as a dramatic actor in the film *The Great Man* (1957). Afterward he appeared in movies and on television in many character roles, notably the dentist in *The Diary of Anne Frank* (1959).

WYNTOUN, wīn'tən, **Andrew of**, Scottish chronicler: b. about 1350; d. after 1420. A canon regular of the priory of St. Andrews, he was elected prior of St. Serf's Inch, Loch Leven, about 1395 and probably held this office until his death. He is known for his *Orygynale Cronykil of Scotland*, in nine books, a metrical account of Scottish history from mythological times to 1408. Although he mixes tradition and history indiscriminately, the later periods are well handled, and the work has considerable philological interest as the earliest chronicle in the Scottish vernacular. It received little attention until 1795, when David Macpherson published part of it. A complete edition of one of the surviving manuscripts was brought out by David Laing (3 vols., 1872-79), and a fully annotated edition of two of the other extant manuscripts was prepared for the Scottish Text Society by François Joseph Amours (6 vols., 1903-14).

WYNYARD, wīn'yərd, town, Saskatchewan, Canada, 125 miles east of Saskatoon by rail and 111 miles north of Regina by road. It is a divisional point on the Canadian Pacific Railroad and the center of a large mixed farming area. The town has grain elevators, a flour and feed mill, a milk pasteurization plant, and a cold storage locker. There are tourist resorts at nearby Big Quill Lake. Wynyard was incorporated as a town in 1911. Population: 2,147.

WYOMING, wi-o'ming, a mountain state of the United States, bordered on the north by Montana, on the east by South Dakota and Nebraska, on the south by Colorado and Utah, and on the west by Utah, Idaho, and Montana. It extends 365 miles (587 km) from east to west and 276 miles (444 km) from north to south. Its name, applied originally to the Wyoming Valley of Pennsylvania, is thought to be derived from the Delaware Indian word *mechwameam-ing*, meaning "at the big plains."

The state has few people, little industry, and no large cities. Much of its area has been devoted

INFORMATION HIGHLIGHTS

Location: Wyoming is a mountain state bordered on the north by Montana, on the east by South Dakota and Nebraska, on the south by Colorado and Utah, and on the west by Utah, Idaho, and Montana.

Elevation: *Highest point*—Gannett Peak, 13,804 feet (4,210 meters); *lowest point*—Belle Fourche River, 3,100 feet (946 meters); *approximate mean elevation*—6,700 feet (2,044 meters).

Total Area (land and inland water): 97,809 square miles (253,326 sq km); rank, 9th.

Resident Population: 453,588 (1990 census). Increase (1980–1990), –3.4%.

Climate: Cool and dry, with wide daily temperature ranges possible. Little rainfall.

Statehood: July 10, 1890; order of admission, 44th.

Origin of Name: May be from a Delaware Native American word, *mechwameam-ing*, which means "at the big plains."

Capital and Largest City: Cheyenne.

Number of Counties: 23.

Principal Products: *Manufactures*—petroleum and coal products, food products, flight instruments and flight testing equipment; *farm products*—cattle, livestock, feed, potatoes, beans, sugar beets, poultry, dairy products, honey; *mining*—petroleum, uranium, coal, bentonite, soda ash, iron ore, sand, stone, gravel.

State Motto: Equal Rights.

State Song: *Wyoming*.

State Nicknames: Equality State; Wonderful Wyoming.

State Bird: Meadow lark.

State Flower: Indian paintbrush.

State Tree: Cottonwood.

State Flag: The state seal on the ribs of a white bison, centered on a dark blue field with a white border, the whole within a red frame. See also **FLAG—Flags of the States**.

streams.

1. The Land

The Great Plains end and the Rocky Mountains begin in Wyoming. Between the rugged peaks of its mountainous terrain are treeless basins, dotted with weathered rock towers called buttes. The most famous of these, Devils Tower, became the first national monument in the United States. The unspoiled natural beauty of Wyoming has changed little since the frontier days of cowboys and Indians. Vast ranches, national forests, recreation areas, and parks occupy most of the sparsely populated land that averages more than 6,000 feet (1,830 meters) in elevation.

Physical Features. Wyoming is a state of high plains, mountains, and occasional badlands. The Great Plains of the eastern section rise gradually to the foothills of the Rocky Mountains, and the Continental Divide crosses the state from the northwest corner to the southern border east of center. There are many high plateaus with elevations between 4,500 and 7,500 feet (1,370-2,285 meters). In the southeast the Laramie Mountains rise over 10,000 feet (3,050 meters), and the Medicine Bow Mountains reach 12,005 feet (3,660 meters) in Medicine Bow Peak. The Bighorn Mountains in the north central section rise to 13,165 feet (4,000 meters) in Cloud Peak. In the northwest the Absaroka Range culminates in Francis Peak (13,140 feet or 4,480 meters), and the Teton Range in Grand Teton (13,766 feet or 4,195 meters). Cannett Peak (13,785 feet or 4,200 meters), the highest mountain in the state, is in the Wind River Range, which includes numerous other peaks over 13,000 feet (3,960 meters) in elevation.

Rivers and Lakes. Wyoming is the source of water for four major drainage systems in the United States—the Missouri-Mississippi; the Interior, or Great Basin; the Columbia; and the Colorado. Most of the drainage is to the north and east into the Missouri-Mississippi system. The tributaries of the Missouri River are the Yellowstone, Clark Fork, Bighorn, Tongue, and Powder rivers flowing north, and the Cheyenne, Niobrara, and North Platte flowing east. The Green River is the major source of the Colorado River. The Snake River is joined by the Salt River and flows into the Columbia. The Bear River, part of the Interior Basin system, flows along the western border of the state into the Great Salt Lake in Utah.

Wyoming has many small, clear mountain lakes, the largest of which are Yellowstone, Jackson, Fremont, and Shoshone. Reclamation projects provide many smaller bodies of water and such man-made lakes as Pathfinder, Seminole, Glendo, Boysen, Alcova, Buffalo Bill, Guernsey, and the huge reservoir on the Green River created by the Flaming Gorge Dam in Utah.

Climate. Wyoming's climate is cool and dry, the dryness serving to temper the coldness of the winters. Because altitudes range from 3,100 feet to over 13,000 feet (945-3,960 meters), local variations are considerable, but Cheyenne may be taken as having a typical Wyoming climate. Because of its 6,131-foot (1,870-meter) elevation, the city is subject to a daily range in temperature averaging 25° F and reaching as much as 40°.

This wide range assures the city of moderately warm days and cool nights during the summer months. Cheyenne has a mean temperature of 45.6° F (8° C), an average daily maximum of 58.9° F (15° C), and an average daily minimum of 32.2° F (0° C). The average precipitation in Cheyenne is 15.06 inches (382 mm), approximately 70% of which occurs during the growing season.

Freezing temperatures may be encountered at the higher elevations every month of the year, but the lower terrain and the eastern valleys have a growing season ranging from nearly three months to a little more than five months. The average precipitation for all reporting stations is 14.31 inches (363 mm) annually.

Plant and Animal Life. Short, tough grass covers much of the treeless eastern plains as well as many of the mountain valleys. In drier areas the grass gives way to sagebrush, greasewood, and cactus. Wyoming supports 150 varieties of grass including Buffalo grass, bluegrass, wheat grass, tufted fescues, and redtops. Mountain wild flowers include buttercup, evening star, forget-me-not, goldenrod, sour dock, and flax.

The mountains are wooded up to the timberline, and forests cover more than 10 million acres (4 million hectares), or about one sixth of the area of the state. About half of this is commercial forest, 80% of which is controlled by the federal government. The major commercial trees are Douglas fir, ponderosa pine, lodgepole pine, and spruce. Mountain mahogany is found in the foot-

The Lower Falls of the Yellowstone River in Wyoming's Yellowstone Park are almost twice the height of Niagara.

Devil's Tower was named as the nation's first national monument by President Theodore Roosevelt in 1906.

hills, along with a variety of shrubs. At lower elevations, cottonwood, willow, and hawthorn trees grow. At middle elevations trembling aspen, junipers, yellow pine, saltbush, and yucca are found. Spruce, fir, and lodgepole pine grow at the higher elevations. Lichens, mosses, and other arctic plants are found growing above the timber line.

Like the plants and timber, Wyoming's animal life varies with the altitude. At lower elevations are coyotes, prairie dogs, ground squirrels, pocket gophers, and cottontail rabbits; at middle elevations, coyotes, jackrabbits, antelope, mule deer, and a few moose; and at higher elevations, snowshoe rabbits, black bear, elk, and an occasional grizzly bear or mountain lion. The sportsman can find game birds including ducks, geese, grouse, pheasants, and wild turkeys and several varieties of trout in the mountain streams. The trumpeter swan, once almost extinct, may be found in both Yellowstone and Grand Teton national parks, along with the white pelican and great blue heron. The bald eagle and the golden eagle also make their home in Wyoming. The only poisonous snake to be found in Wyoming is the prairie rattlesnake.

Mineral Resources. Wyoming's first productive oil wells were drilled in 1883 in the Dallas Field. All counties except Teton and Platte produce oil, and since World War II petroleum has been of tremendous economic importance. Wyoming also produces natural gas, coal, and trona (hydrated sodium bicarbonate). Major uranium deposits are located in the basins of the Powder, Shirley, and Wind rivers. There are also several deposits of iron ore in the state.

Other mineral resources include gemstones, particularly agate and jade, and stone, gypsum, bentonite, clay, pumice, vanadium, limestone, sulfur, and vermiculite.

Conservation. The low rainfall made many people conservation conscious early in the history of Wyoming settlement. The state delegation to Congress, beginning in 1890 with Senators Joseph M. Carey and Francis E. Warren, worked hard for the extension of federal assistance in the conservation and use of water for irrigation and power.

Yellowstone Park Timberland Reserve (now Shoshone National Forest), the nation's first timber reserve, was established in 1891. Severe droughts in the 1930's and 1950's emphasized the need for conservation of soil and water, and by 1958, two thirds of the state had been organized in 44 soil conservation districts. There were also eight Bureau of Reclamation irrigation projects (Minidoka, Eden, Riverton, Shoshone, Kendrick, North Platte, Hanover Bluff, Owl Creek, and Seedskaadee) and a number of hydroelectric power plants.

Conservation of oil and gas resources has met resistance from interests eager for quick exploitation, but since 1919 the legislature has eliminated the worst excesses, and in 1951 a state oil and gas conservation commission was established. Conservation of animal resources is supervised by the

The broad and rolling winter terrain of Union Pass in the Wind River Range is popular with snowmobilers.

1980	62.7 (U.S., 73.7)	37.3

Texas and the Midwest. The state's Native American population is about 9,500, many of them Arapahoe and Shoshone who live on the Wind River Indian Reservation.

The people of Wyoming are mainly Protestant. About 6% are Mormons, and about 18% are Roman Catholics. Protestant denominations include Methodist, Episcopalian, Presbyterian, Lutheran, Baptist, Disciples of Christ, Seventh-Day Adventist, and United Church of Christ. The Eastern Orthodox Church also is represented.

Wyoming's electoral votes have been about equally divided between Democratic and Republican presidential candidates since the early 1930's. The cities in the southern part of the state are mainly Democratic, balancing the rural areas to the north, which are largely Republican.

A rancher ropes a stray calf. Cattle are the chief source of Wyoming's agricultural income.

FRITZ HENLE/PHOTO RESEARCHERS

Wyoming game and fish commission. In addition, the state has four national wildlife refuges and the National Elk Refuge.

2. The People

In the late 19th century, Wyoming was a "Cattlemen's Commonwealth," and the dominant cattlemen resented encroachments by homesteaders on the public lands they had been using. The day of the cattleman has never really ended, although people with other economic interests have a greater voice than they once had. A cowboy astride a bucking horse adorns Wyoming license plates, and every summer dozens of rodeos throughout the state recall the cow country life of the 1880's.

Characteristics of the Population. Most of the approximately 454,000 residents of Wyoming are American-born, and many of them are direct descendants of the original settlers who came from

COURTESY PACIFIC GAS TRANSMISSION CO

Drilling rigs are a familiar sight in Wyoming. All but two of the state's counties are producers of petroleum.

Main Centers of Population. More than half of Wyoming's people live in urban areas. The state contains only a few moderate-size cities. Most of the cities are located in the southern part of the state along its major interstate highway. Cheyenne, the capital and largest city, has a population of about 50,000 and is an intercontinental missile-launching center with growing economic diversification. The second-largest city is Casper, the oil "capital" and a center for cattle, sheep, and wholesaling. Other important cities in Wyoming are Laramie, a university town; Rock Springs, a wool and coal-mining community; and Sheridan, a cattle, dude ranch, and tourist center.

3. The Economy

Until 1910 the economy of Wyoming was based on cattle and sheep, with some support from rail transportation and coal mining. Later these were supplemented by the extensive production of petroleum, particularly after World War II; the tourist business; some expansion of farming; and, beginning in the 1950's, uranium mining and milling. Efforts to attract large-scale industrial plants have been generally unsuccessful, and the state is the least industrialized in the Union.

Mining. Mining is the most important industry in Wyoming, and petroleum is its major product. There are over 10,000 producing oil wells and over 900 natural gas wells in the state.

Wyoming is the nation's leading uranium producer. Uranium was first discovered and mined in the Silver Cliff mine in Lusk in 1918. In 1953 mining operations began in the Pumpkin Buttes area of Campbell county. Important uranium mines are located in Big Horn, Carbon, Campbell, Converse, Crook, Fremont, Johnson, and Natrona counties. The main center for the milling of uranium is Riverton.

Coal production is a rapidly expanding industry. The main fields of Wyoming's vast beds of bituminous and subbituminous coal are located at

Rock Springs, Hanna, Kemmerer, Sheridan, Gillette, and Glenrock. Wyoming is also a leader in the production of bentonite and soda ash. Among its other mineral products are iron ore, sand, stone, and gravel.

Agriculture and Ranching. Ranching is the state's second most important industry. A large portion of the state is covered with ranches and farmlands. About 90% of the agricultural land is used for grazing, and only 6% for crops. Many of the crops raised are used to feed livestock. The principal crops are beans, sugar beets, alfalfa, wild hay, wheat, oats, barley, corn, and potatoes. Other agricultural products are poultry, dairy products, eggs, horses, and honey.

Although the number of ranches and farms in Wyoming (about 7,000) has tended to decrease, their average size (about 4,875 acres, or 1,950 hectares) has increased. Ranchers may lease federal lands for grazing, and with special permission, these lands may be fenced.

Manufacturing. Almost all of the manufacturing is concerned with processing petroleum and

coal products, uranium, and other minerals mined in the state. Food processing, particularly sugar refining and the manufacture of cheese and meat products, and the manufacture of flight instruments and flight testing equipment constitute the bulk of the state's other manufacturing industries.

Transportation. Two east-west routes in southern Wyoming that cross the Continental Divide have been used by every means of land transportation in Wyoming's history. One of these routes became U. S. 80, a major interstate highway that crosses the nation. Stage lines operated here in the 1850's. In 1860-1861 the Pony Express provided fast communication.

Between 1867 and 1869 the main line of the Union Pacific Railroad was built across southern Wyoming. Today Wyoming has about 2,400 miles (3,862 km) of railroad track serving passengers and freight, including one of the few north-south lines in the west, and 20,000 miles (32,185 km) of maintained roads and highways.

There are about 90 airports in the state. The busiest commercial airports are those at Cheyenne and Casper.

4. Government

Wyoming's constitution as approved at the time of statehood in 1890 has not been changed very much, although some parts have been modi-

Thousands of elk migrate each winter to a refuge near Jackson when their usual forage is buried by snow.

JOAN KRAMER AND ASSOCIATES/A. DEVANEY, INC., N. Y.

PHOTO FROM EUROPEAN/PPA

The State Capitol was built at the end of the 19th century in Cheyenne, Wyoming's capital city since 18

fied by amendments. To call a new constitutional convention or to add amendments is difficult. In either case, a two-thirds vote of each branch of the legislature must be followed by the approval of a majority of the electors who cast any ballots at the next general election.

Voters in Wyoming must be citizens of the United States, at least 18 years of age, and residents of the state for one year, of the county for 60 days, and of the district for ten days. The state sends two senators and one representative to the U. S. Congress.

Structure of Government. The state's chief executive is the governor, who is elected to a four-year term and may serve an unlimited number of terms. There is no lieutenant governor. If a vacancy occurs, the secretary of state serves as governor until the next general election. Other elected officials in the state are the secretary of state, auditor, superintendent of public instruction, and treasurer. All are elected for four-year terms and may serve for an unlimited number of terms, except the treasurer who may not succeed himself. The governor appoints several important state officials, including the attorney general and the heads of the budget and personnel departments. He has the right to veto legislation passed by the state legislature, but his veto may be overridden by a two-thirds vote in each house of that body.

Wyoming has a bicameral legislature consisting of a Senate and a House of Representatives. The 30 senators are elected to four-year terms, and the 62 representatives are elected to two-year terms. The legislature meets annually. General sessions are opened on the second Tuesday of January in odd-numbered years. Budget sessions convene in even-numbered years beginning on the second Tuesday of January. Sessions may not last longer than 40 days in one year, or 60 in two. Special sessions may be called by the governor.

Wyoming has a state supreme court of five justices appointed by the governor for eight-year

GOVERNMENT HIGHLIGHTS

Electoral Vote—3. **Representation in Congress**—U. S. senators, 2; U. S. representatives, 1. **State Legislature**—Senate, 30 members, 4-year terms; House of Representatives, 62 members, 2-year terms. **Governor**—4-year term; may serve consecutive terms.

terms. The justices elect one of their own members as chief justice. The court's jurisdiction is primarily appellate. There are also nine judicial districts each with either one or two judges, appointed to six-year terms. District courts have general original jurisdiction and limited appellate jurisdiction from inferior local courts, which include police courts, municipal courts, and justice-of-the-peace courts.

Public Finance. Wyoming has no individual or corporate income taxes. The state's principal sources of revenue are sales taxes, license fees, and property taxes, in that order. Taxes provide only slightly more than half of the state's income, the rest of its revenue being derived from federal grants and other U. S. governmental programs.

Social Services. The state department of public welfare administers aid to dependent children, old-age assistance, aid to the blind, aid to the totally and permanently disabled, and general assistance. The five elective officers of the state government, sitting together as the board of charities and reform, supervise the operation of the State Children's Home, for dependent children, in Casper; the Wyoming Industrial Institute, for delinquent boys, in Worland; the Wyoming Girls' School, for delinquent girls, in Sheridan; the Wyoming State Penitentiary, in Rawlins; the Wyoming State Prison Farm, in Riverton; the Wyoming State Hospital, for the mentally ill, in Evanston; the Wyoming State Training School, for the mentally deficient and epileptic, in Lander; the Wyoming Tuberculosis Sanatorium, in Basin; the Wyoming Pioneer Home, for the aged, in Thermopolis; and the Wyoming Soldiers' and Sailors' Home, in Buffalo.

5. Education and Culture

Education. The first school in what is now Wyoming was established at Fort Laramie in 1852. A school was opened in 1868 at Cheyenne where, in 1875, the first high school in the territory also was established. Meanwhile, in 1869, a territorial school law was enacted. The state board of education was not established until 1919.

Elementary and Secondary Education. The public elementary and secondary schools of the state are supervised by the elected state superintendent of public instruction. The nine members of the state board of education are appointed by the governor with Senate approval for six-year terms. Most of the funds for the public school system come from property taxes. Education is compulsory between the ages of 7 and 16. In addition to the public schools, there are several parochial elementary schools and parochial high schools in Cheyenne and at an Indian mission.

Higher Education. The University of Wyoming, a land-grant institution in Laramie, opened with a handful of students in 1887. It is the only four-year institution of higher learning in the state and includes colleges of agriculture, arts and sciences, commerce and industry, education, engineering, law, nursing, and pharmacy, and a graduate school. The state also has seven publicly supported junior colleges located in Casper, Riverton, Torrington, Powell, Sheridan, Rock Springs, and Cheyenne.

Libraries and Museums. The state's largest library is the William Robertson Coe Library at the University of Wyoming, whose holdings include a collection of documents on Western his-

tory. Next in size is the State Library in Cheyenne, containing a fine collection of law books. All the counties maintain libraries.

Wyoming has over 50 museums, most of which feature Indian and pioneer relics. The Whitney Gallery of Western Art at the Buffalo Bill Historical Center in Cody features a fine collection of documentary art of the Old West, with paintings and sculpture by such noted artists as Frederic Remington, Charles M. Russell, and Albert Bierstadt. The state archives are housed at the Wyoming State Museum in Cheyenne. The state also maintains historical museums in Fort Bridger and the Wyoming Pioneer Museum in Douglas. The National Park Service operates the Fur Trade Museum in Moose, natural history museums at Devils Tower National Monument, Grand Teton National Park, and Yellowstone National Park, and a historical museum at Fort Laramie National Monument. The University of Wyoming has a geological museum and a herbarium.

Other museums of interest are the Jim Gatchell Memorial Museum in Buffalo, with mementoes and photographs of the Old West; the Cheyenne Frontier Days Old West Museum adjacent to Frontier Park; the Buffalo Bill Museum, the Winchester Museum, and the Plains Indian Museum in Cody; the Wyoming Pioneer's Memorial Museum in Douglas, containing extensive displays of pioneer items, Indian relics, maps, charts, newspapers, and photographs; the Grand Encampment Museum at Encampment; the Jackson Hole Historical Museum; the rock collection at the Fremont County Pioneer Museum; the Laramie Plains Museum; the Stagecoach Museum in Lusk; the Riverton Museum, which features Shoshone and Arapahoe costumes and artifacts; the Bradford Brinton Memorial Ranch in Sheridan, recreating the atmosphere of Western ranch life; and the Trail End Historical Home and Museum in Sheridan, the former home of U. S. Senator John B. Kendrick.

Other Cultural Activities. Art activities are sponsored by the Wyoming Arts Council, the Wyoming Artists Association, numerous county art guilds, and the art departments at the University of Wyoming and the junior colleges. Prominent nonacademic artists include Joe and Mary Back, Rupert Conrad, Nick Eggenhofer, Grant Hagen, Evelyn C. Hill, Conrad Schwiering, and Archie Teater. Robert I. Russin of the University of Wyoming has done outstanding work in sculpture. The leading art collection is in the Whitney Museum of Western Art in Cody, which includes many Frederic Remington pictures donated by the William Robertson Coe Foundation.

Prominent among the active musical organizations in the state are the Cheyenne Symphony and Choral Society, the Casper Civic Symphony, and the University of Wyoming Orchestra, String Quartet, Chorus, and Glee Club. Little-theater performances are given in the larger cities, but most of the drama activity is at the University of Wyoming.

Communication. The first newspaper in Wyoming, the *Daily Telegraph*, was published at Fort Bridger in 1863. Of the approximately 40 newspapers in the state, ten are dailies. The *Casper Star Tribune* and Cheyenne's *Wyoming State Tribune* and *Wyoming Eagle* have the largest circulation.

The first radio station began broadcasting at Casper in 1930. The first television station began

in Cheyenne in 1954. There are about 30 radio stations and four television stations in the state.

6. Recreation and Places of Interest

Two million visitors a year visit Yellowstone and Grand Teton national parks. Thousands more come for the winter sports, hunting and fishing, and dude ranches, but the state's other attractions offer a tremendous potential for tourism that has not as yet been fully explored.

Parks and Recreation Areas. The major tourist attractions in the state are its two national parks, Yellowstone and Grand Teton. Yellowstone, the state's largest and best-known park, was established in 1872 as the first national park in the United States. The park features the world's most celebrated geyser, Old Faithful; Mammoth Hot Springs; Yellowstone Lake; the Grand Canyon of the Yellowstone along the Yellowstone River between Canyon Village and Tower Junction; and black bears in the back country. Grand Teton is equally spectacular. Both parks offer a variety of trails for hiking and viewing the colorful scenery. There are four national forests within the state—Shoshone, Medicine Bow, Bridger-Teton, and Big Horn—and five more that extend into other states as well. Black Hills is shared with South Dakota, Caribou with Utah and Idaho, Targhee with Idaho, and Ashley and Wasatch with Utah. Recreation areas include Flaming Gorge National Recreation Area, bounded on the south by Red and Horseshoe canyons and on the north by cliffs and promontories.

The ten state parks and recreation areas include Boysen, the largest; Hot Springs, containing the world's largest hot springs; Buffalo Bill; Curt Gowdy; Glendo; Guernsey; Keyhole; Saratoga Lake; Seminoe; and Sinks Canyon. Added to these are a number of wildlife and animal preserves, the most famous of which is Jackson Hole refuge for elk.

Historical Sights and Monuments. A great many monuments to the Old West abound in Wyoming. These include Old Fort Caspar, a replica of the original fort at Casper; the statue of Buffalo Bill in Cody; the Devils Tower National Monument in the northwestern part of the state, the first national monument in the United States; Fort Laramie National Historic Site; Fort Bridger State Historic Site; Fossil Butte National Monument, with the world's largest deposits of fossilized fish; Cunningham Cabin in Grand Teton National Park; the Oregon Trail State Historical Site in Guernsey; and the Fetterman Massacre Monument in Sheridan.

Trails and Float Trips. Among the most outstanding of the many hiking trails in the state are the Amphitheater Lake Trail, Cascade Canyon Trail, Death Canyon Trail, Paintbrush Trail, Teton Crest Trail, and Valley Trail in Grand Teton National Park.

Numerous float trips are available in the most scenic parts of the state, including those on the Wyoming River, the Shoshone River at Cody; in Grand Teton National Park; and on the Snake River at Jackson. Wagon-train and prairie-schooner excursions are also available in Jackson.

Other Places of Interest. The state has numerous dude ranches, lodges, fishing resorts, and other tourist attractions. Among them are the Periodic Spring at Afton, which stops flowing every 18 minutes in late summer and then begins again and gradually builds to a thundering torrent; the sandstone neoclassic State Capitol and

the governor's mansion in Cheyenne; Old Trail Town, a reconstruction of the log cabin used as a hideout by Butch Cassidy and the Sundance Kid in Cody; Ayres Natural Bridge in Douglas; South Pass City, a gold-mining ghost town; and Wind River Canyon at Thermopolis.

Annual Events. Most of the state's major events are rodeos, the most famous of which is the nine-day Cheyenne Frontier Days held the last week of July. Other July rodeos include the Cody Stampede, Lander's Pioneer Days Rodeo and Parade, and those held at Dubois, Pinedale, Sheridan, and Rawlins. The Central Wyoming Fair and Night Rodeo in Casper, the Western Plains Fair in Cheyenne, and the Wyoming State Fair in Douglas take place in August. The Grand Teton Music Festival, held from mid-July to mid-August, features symphony concerts, a film festival, and an art exhibit. Pageants include the Green River Rendezvous in Pinedale in July and the Gift of the Waters Pageant in Thermopolis in August. From mid-June through Labor Day the Cache Creek Posse stages a mock robbery nightly in the Jackson town square. The Shoshone and Arapahoe Indians hold traditional three-day sun dances near Dubois during July. An Oktoberfest is celebrated in Worland, and horse-drawn sleigh races are held from January to April in Afton, Big Piney, Jackson, and Pinedale.

7. History

The early history of Wyoming reads like a classic Western novel, with a cast of Indians, trappers, cattlemen, and miners. The hero, of course, is the cowboy. The taming of Wyoming came under six different flags—of Spain, Britain, Mexico, France, the Republic of Texas, and the United States. The state's history has been shaped and affected by murder, arson, range wars, and natural disasters, but its pioneer traders and settlers proved to be as rugged and indestructible as its scenery.

Exploration. Before the arrival of the white man, Indian tribes roamed over the region now known as Wyoming. Among them were the Sioux, Cheyenne, Arapahoe, Crow, and Shoshone. The first white men to reach the area were probably the brothers François and Louis Joseph de la Vérendrye, who traveled southwest from the Mandan villages in 1742-1743 and may have reached the Bighorn Mountains. Toward the end of the 18th century other Frenchmen penetrated to the Wyoming country via the North Platte River.

John Colter, a veteran of the Lewis and Clark Expedition, spent the winter of 1807-1808 in northwestern Wyoming. Presumably he visited a hot-springs area just west of the present town of Cody that became the Colter's Hell of trapper stories. He also crossed through what is now Yellowstone Park, the first white man to do so. Wilson Price Hunt, an employee of John Jacob Astor, led a fur-trading expedition westward through northern Wyoming in 1811 on his way to Astoria, Oregon. The following year, Robert Stuart, another Astor employee, led a small party from Oregon through Wyoming, suffering great hardships. The party crossed the Continental Divide in the vicinity of South Pass and made its way eastward along the North Platte. In 1823-1824 a party representing the Rocky Mountain Fur Company entered Wyoming from Montana, traversed the Bighorn Basin, and crossed through South Pass. Jedediah Smith, Thomas Fitzpatrick, and James Clyman, who were in the party, often

are credited with being the first white men to go through South Pass, the gateway to the West, although the Stuart party may have done so.

In the 1820's and 1830's increasing numbers of trappers came to Wyoming for precious beaver pelts. They lived not unlike Indians, at whose hand many of them died. William Henry Ashley in 1825 organized the first trappers' rendezvous on Henry's Fork of the Green River. For the next 15 years the rendezvous was an annual affair. Trappers, white and Indian, assembled in early summer at a prearranged place to dispose of their winter's catch, to get fresh supplies, and to enjoy the conviviality they had missed during the long winter. With the decimation of the beaver, however, the rendezvous system ended in 1840.

Meanwhile, other motives than "beaver gold" began to send people along the trappers' trails. Sportsmen, scientists, and missionaries accompanied the caravans bound for the fur-trade rendezvous in the 1830's. Among these were the Methodist missionaries Jason and Daniel Lee and the botanist Thomas Nuttall, all in 1834; Samuel Parker and Marcus Whitman, in 1835; and Mrs. Whitman and Mrs. Henry H. Spalding, the first

FAMOUS WYOMINGITES

Arnold, Thurman Wesley (1891-1969), lawyer, trust-buster, author of *The Folklore of Capitalism* (1937).

Barrett, Frank A. (1892-1962), political leader.

Burt, Struthers (1882-1954), novelist.

Carey, Joseph M. (1845-1924), lawyer and political leader who introduced bill for Wyoming's statehood, one of the first U. S. senators from Wyoming (1890-1895), governor of Wyoming (1911-1915).

Clough, Wilson (1894-), poet.

Crane, A. G. (1877-1955), educator.

Curry, Peggy Simpson (1911-), writer and novelist.

Hayden, Ferdinand Vandiveer (1829-1887), geologist who surveyed the Rocky Mountains and urged that Yellowstone become a national park.

Hebard, Grace Raymond (1861-1936), historian, librarian, trustee, and professor of political economy at the University of Wyoming, leader in women's suffrage.

Hill, Evelyn Corthell (1886-), painter.

Hopkins, Lin (1886-), painter.

Humphrey, G. D. (1897-1973), educator.

Kendrick, John B. (1857-1933), rancher and politician, first Democratic U. S. senator from Wyoming (1917-1933).

Lockhart, Caroline (1875-1962), novelist.

Mondell, Frank W. (1860-1939), prospector, politician, U. S. representative (1895-1897, 1899-1923), House majority leader (1919-1923).

Morris, Esther Hobart (1814-1902), first woman justice of the peace in the United States.

Nye, Edgar Wilson "Bill" (1850-1896), humorist and journalist.

Olsen, Ted (1899-), poet.

O'Mahoney, Joseph Christopher (1884-1962), journalist, lawyer, politician, U. S. senator (1934-1960).

Pollock, Jackson (1912-1956), abstract expressionist painter.

Tinehart, Mary Roberts (1876-1958), novelist and mystery writer.

Toss, Nellie Tayloe (1876-1977), first woman governor in the United States (1925-1927), elected to fill unexpired term of her husband, Gov. William Bradford Ross, who died while in office, and first woman director of U. S. Mint (1933-1953).

Tuslin, Robert I. (1914-), sculptor.

Uchiering, Conrad (1916-), painter.

Timpson, Gov. Milward L. (1897-), lawyer, political figure, governor of Wyoming (1955-1959), U. S. senator (1963-1969).

Van Devanter, Willis (1859-1941), lawyer, justice associate justice of U. S. Supreme Court (1913-1937).

Varren, Francis E. (1844-1929), political leader.

Old Faithful, erupting about every hour, is the most famous of Yellowstone's 3,000 geysers and hot springs.

white women to enter Wyoming, who came with their husbands in 1836. Father Pierre Jean De Smet, a Roman Catholic missionary, came with the supply train of 1840.

Settlement. In the 1840's, homeseekers in growing numbers moved through Wyoming along well-marked trails to Oregon, California, and Utah. Two small communities offered the weary travelers opportunities to secure supplies, repairs for their wagons, and replacements for their worn-out draft animals. Fort Laramie, near the junction of the Laramie and North Platte rivers in eastern Wyoming, was for many years the best-known settlement in the Rocky Mountain region. Established as a private fur-trading post in 1834, it was sold to the U. S. government in 1849 and became an Army post.

The other port of call was Fort Bridger on Blacks Fork of the Green River in southwestern Wyoming, which was opened by the famous trapper, guide, and storyteller James Bridger in 1843. Both forts were busy places in summer and very quiet in winter. In 1842 and again in 1843, Lt. John Charles Frémont of the Corps of Topographical Engineers visited Fort Laramie, and in 1845 Col. Stephen W. Kearny led five companies of the 1st Dragoons over the Oregon Trail to South Pass. See also OREGON TRAIL.

In the dozen years following 1841, more than 150,000 persons crossed South Pass westward bound. Brigham Young led the first party of Mormons through the pass in 1847, and perhaps 50,000 California-bound gold seekers passed through in 1850. The Indians understandably were alarmed at the number of whites who were using the Oregon Trail. Wild game disappeared for many miles on either side of the broad highway, misunderstandings arose, and occasionally white travelers suffered from Indian depredations.

FRED RAGSDALE/TPS

Fort Laramie's Old Bedlam, built in 1851 of lumber hauled 800 miles (1,287 km), is the oldest building in Wyoming.

To head off worse troubles, a great treaty council was held below Fort Laramie in 1851. Perhaps 10,000 Indians from several tribes were present to hear government spokesmen. In return for assurances that they would allow unmolested travel on the trails, the Indians were promised an annuity of \$50,000 in goods for 50 years.

The treaty was not a cure-all. In 1854, just below Fort Laramie, Lt. John L. Grattan, a corporal, 27 privates, and an interpreter were killed in the so-called Grattan massacre. Although the incident caused strained relations, there was little further violence until the 1860's, when an effort to open the Bozeman Trail from Fort Laramie to the Montana goldfields brought open war in northern Wyoming. The trail led through a favorite Sioux hunting ground east of the Bighorn Mountains. Near Fort Phil Kearny, Lt. Col. William J. Fetterman and 81 men were ambushed and slain on Dec. 21, 1866.

War continued until 1868, when another Fort Laramie treaty provided for the withdrawal of garrisons from the Bozeman Trail. That same year a treaty made at Fort Bridger established the Wind River Indian Reservation in central Wyoming for the peaceful Shoshone. The Arapahoe were moved to the same reservation in 1878. Meanwhile, northern Wyoming was made safe for whites when Sitting Bull's hostile Sioux fled to Canada after the Custer massacre in southern Montana in 1876.

Statehood. The Union Pacific Railroad entered southern Wyoming in 1867 and had crossed into Utah by 1869. Cities sprang up along its route—Cheyenne, Laramie, Rawlins, Rock Springs, Green River, Evanston—and this influx of population gave strength to a movement to organize Wyoming as a territory. From time to time the Wyoming region had been a part of various territories and was included in Dakota Territory in 1868, when Congress passed an act (July 25) creating Wyoming Territory. One of the first acts of the new territorial government

was to give women the right to vote and to hold office. The measure was signed by Gov. John A. Campbell on Dec. 10, 1869. The 1870 census showed 9,118 people in the territory. Rapid growth thereafter brought demands for statehood, which led to the admission of Wyoming to the Union on July 10, 1890. The state was given the same boundaries the territory had had.

Hundreds of thousands of Texas longhorns were trailed into Wyoming in the 1870's and

HISTORICAL HIGHLIGHTS

- 1807 John Colter was the first white man to see the geysers and hot springs in the Yellowstone area.
- 1833 Oil was discovered east of the Wind River Mountains.
- 1834 William Sublette and Robert Campbell established Fort William (now Fort Laramie) on the Oregon Trail.
- 1843 Fort Bridger was established by James Bridger.
- 1867 The Union Pacific Railroad entered Wyoming.
- 1868 The Territory of Wyoming was created by Congress.
- 1869 Women were granted the right to vote and hold elective office in Wyoming.
- 1872 Yellowstone became the first national park in the United States.
- 1883 Wyoming's first oil well was drilled in the Dallas Field.
- 1890 Wyoming became the 44th state of the union on July 10.
- 1892 The Johnson County War between cattlemen and homesteaders broke out after a dispute over cattle rustling.
- 1906 Devils Tower became the first national monument in the United States.
- 1910 Shoshone Dam (now Buffalo Bill dam) was completed.
- 1925 Nellie Tayloe Ross became the first woman governor in the United States.
- 1929 Grand Teton became a national park.
- 1951 Uranium was discovered in Wyoming.
- 1958 F. E. Warren Air Force Base became the first U.S. intercontinental ballistic missile base.
- 1965 Minuteman missile project was completed near Cheyenne.
- 1974 Operations began at the Jim Bridger Power plant in Rock Springs.

1880's, and the state became a "Cattlemen's Commonwealth" dominated by a few hundred members of the Wyoming Stock Growers Association. For a number of years the open-range cattle business flourished, but too many cattle were thrown on the range, and the terrible winter of 1886-1887 brought disaster. Cattlemen who were fortunate enough to avoid bankruptcy then reorganized their industry; in particular, they made provision for supplementary winter feed and water. Sheepmen took advantage of the cattlemen's difficulties, and during the years 1908 to 1910 the wool industry led all others in the state.

The cattlemen lashed out against their assorted enemies on two occasions. In 1892 some of them launched an invasion of Johnson county in search of rustlers whom they had listed for execution. The invaders succeeded in killing only two of the men on their list before a sheriff's posse surrounded them. A U. S. cavalry detachment appeared opportunely, and the invaders were taken to Cheyenne for trial. Nine months later the case against them was dismissed for lack of evidence, much to the disgust of the people of Johnson county. The second act of violence came in 1909, when a group of cattlemen attacked a sheep camp near Ten Sleep, killing two prominent sheepmen and a herder. Five of the cattlemen received penitentiary sentences for the crimes. That ended the resort to extra-legal methods of settling range disputes.

The Modern Era. As the 20th century advanced, Wyoming citizens conformed more closely to the ways of people farther east. Population growth paralleled that of the nation, evidence of the state's maturity. In three wars, Wyoming excelled most other states in patriotic enthusiasm and willingness to make sacrifices. In the Spanish-American War the state exceeded its quota of volunteers four and one-half times, and it was claimed that a Wyoming unit raised the first U. S. flag over Manila. In World War I the state sent 11,393 young men into uniform. In World War II approximately 30,000 of the state's young men and women were in uniform, and 1,095 of them died. During and after the war, efforts were made, with small success, to bring manufacturing industry to Wyoming as some citizens wanted the state to have a broader economic base than that provided by raw-materials production and tourists.

The threat of nuclear war affected the state directly in the late 1950's. Purchase by the federal government of uranium ore spurred prospecting until enough ore bodies had been located to give Wyoming second place among the states in production and first in known reserves. Defense preparations also led to the establishment of an intercontinental ballistic-missile-launching base at Cheyenne in 1958.

In the late 1960's and 1970's state leaders renewed their efforts to attract manufacturing plants, without which the state appeared destined to remain only sparsely settled. In 1969 the Wyoming department of economic planning and development replaced the natural resources board in an effort to attract more industry.

Environmental conservation is another major concern of the state. A new agreement with the federal government in 1979 permits the state to regulate mining and reclamation on federal lands within the state.

WYOMING, a city in southwestern Michigan, in Kent county, on the Grand River, adjoining Grand Rapids. Major industries include the manufacture of refrigerators, automobile bodies, and metals. Indian Mounds Park, which contains an old Indian burial ground, is nearby on the Grand River. The first land grant in Wyoming township, signed by President Andrew Jackson, is dated Dec. 1, 1835. The township was incorporated as a home-rule city on Jan. 1, 1959. Government is by commission and city manager. Population: 63,891.

WYOMING, University of, a coeducational land-grant university in Laramie, Wyo. It was chartered by the territorial legislature in 1886 and opened to students the following year. The university has colleges of agriculture, arts and sciences, commerce and industry, education, engineering, law, and health sciences and a graduate school. Bachelor's, master's, and doctor's degrees are granted. In addition, the Division of Adult Education and Community Service conducts extension courses throughout the state and field summer schools.

The university campus of more than 700 acres (283 hectares) is situated near the center of Laramie in a beautiful setting between the Laramie and Medicine Bow mountains. Outstanding newer structures are the William Robertson Coe Library and Fine Arts Center.

Government of the university is vested in the Board of Trustees, whose 12 voting members are appointed by the governor of Wyoming, with the consent of the state Senate, for overlapping terms of six years. In addition, the governor, state superintendent of public instruction, president of the university, and student body president are ex officio members of the board. Full-time enrollment is about 7,500.

WYOMING VALLEY, a valley in northeastern Pennsylvania, in Luzerne county, along the Susquehanna River. Shaped like a crescent, about 20 miles (33 km) long and 3 to 4 miles (5-7 km) wide, the valley is a fertile alluvial plain, with rich anthracite coal deposits, and is noted for its beauty. The chief city in the area is Wilkes-Barre.

The Wyoming Valley was first settled permanently by emigrants from Connecticut, organized in the Susquehanna Company, beginning in 1769. For the next 30 years it was the object of a bitter dispute between Connecticut and Pennsylvania (see PENNAMITE WARS).

During the American Revolution the valley was the scene of the Wyoming Massacre (July 3, 1778), when Butler's Rangers (see BUTLER,

JOHN) and a force of British and Indians descended on the valley. Most of the able-bodied men among the settlers had joined the Continental Army. The 300 men who remained, mostly old men and boys, gathered at Forty Fort, near Wilkes-Barre, for the defense. Outnumbered by 1,100 enemies, including 700 Indians, about two thirds of the defenders were slain in battle, and many of the survivors who surrendered were tortured and killed by the Indians.

WYSPIAŃSKI, vis-pyän'yə-skē, Stanisław (1869–1907), Polish dramatist and artist. He was born in Kraków on Jan. 16, 1869, and studied literature and fine arts. Regarded as the most creative Polish dramatist of the late 19th and early 20th century, he devoted a number of his plays to Polish national history, including *Legenda I* (1897), its sequel *Legenda II* (1904), *Bolesław Smiały* (1903), and *Skalka* (1905–1907), all set in the Middle Ages; the unfinished *Zygmunt August* (1907), inspired by the Polish Renaissance; and *Legion* (1900), on the legion formed in Italy in 1848 by the Polish romantic poet Adam Mickiewicz. The best of Wyspiański's historical dramas, *Warszawianka* (1898) and *Noc listopadowa* (1904), treat the events of the ill-fated Polish uprising of November 1830.

Wyspiański also wrote a cycle of plays based on classical Greek antiquity: *Meleager* (1897; Eng. tr., 1933), *Protesilas i Laodamia* (1899; Eng. tr., 1933), *Achilleis* (1903), and *Powrót Odysa* (1907). In *Klątwa* (1899; *The Curse*), *Sędziowie* (1900; *The Judges*), and *Wesele* (1901; *The Wedding*), he dealt with various aspects of contemporary Polish life. The most interesting of these plays is *Wesele*, inspired by the marriage of the poet Lucjan Ryden to a peasant girl from the village of Bronowice near Kraków. For the structure of the drama, Wyspiański utilized techniques borrowed from the ancient Kraków Nativity puppet play, known in Polish as *szopka*. *Wesele* was an outstanding success and is a classic of the Polish theater.

As an artist, Wyspiański was noted for his designs for stained-glass windows. In 1905 he joined the faculty of the fine arts academy in Kraków. He died in Kraków on Nov. 28, 1907.

HAROLD B. SEGEL*, *Columbia University*

WYSS, vēs, Johann Rudolf (1782–1830), Swiss author. He was born in Bern on March 4, 1782. Educated at various German universities, he was named professor of philosophy at the Bern Academy in 1805.

Wyss is best known for the story *Der schweizerische Robinson* (4 vols., 1812–1827), translated into English as *The Swiss Family Robinson*. This account of the adventures of a family wrecked on a desert island, patterned after Daniel Defoe's *Robinson Crusoe*, was mainly written by Wyss' father, a clergyman, for the amusement of his family. The younger Wyss completed and edited the novel, which has been a favorite story for children since it was first published. See SWISS FAMILY ROBINSON.

In 1811, Johann Rudolf Wyss wrote the Swiss patriotic song *Rufst du, mein Vaterland?* (*Call'st Thou, My Fatherland?*) to the music of *God Save the King*. He also collected and edited material from Swiss history and lore, published in several books and in the literary magazine *Die Alpenrosen*, which he edited from 1811. Wyss died in Bern on March 21, 1830.

WYTHE, with, George (1726–1806), American patriot, judge, and legal educator, who was a signer of the Declaration of Independence. He was born in Elizabeth City county (now part of the city of Hampton), Va., the son of a landed family with Quaker antecedents. He received a rudimentary classical education from his mother and briefly attended grammar school. Because the family estate had been inherited by his elder brother at their father's death in 1729, Wythe read to be a lawyer and was admitted to the bar in 1746. He traveled on the circuit, but after the death of his wife, the former Ann Lewis, in 1748, he moved to the Virginia capital of Williamsburg. After serving as a legislative clerk he was attorney general and a member of the House of Burgesses.

In 1755, Wythe married Elizabeth Taliaferro and in that year inherited the family estate from his brother. By 1760 he had established a flourishing law practice and was attracting students to his office, including Thomas Jefferson, whose views he influenced deeply.

In 1764, Wythe vigorously challenged the proposed Stamp Act and wrote the legislature's resolution protesting its unconstitutionality. In 1765, however, with Richard Bland and several other anti-Stamp Act burgesses, he opposed Patrick Henry's Stamp Act resolutions as illogical and inopportune, since the king and Parliament still had the previous resolution under consideration. An advocate of autonomy for the colonies within the British Empire, and then of independence, he was a delegate to the Second Continental Congress and a signer of the Declaration of Independence.

Returning to Virginia in 1776, Wythe entered upon a distinguished career as a judge and legal educator. He was appointed with Thomas Jefferson, George Mason, and Edmund Pendleton to revise and draw up a law code for the state. In 1778 he was elected one of the three justices of the new High Court of Chancery, and after a court reorganization in 1789 he was the sole justice of the High Court until 1801. A stern, fair, and impartial judge, he was characterized by his contemporaries as methodical, logical, and sound, but not brilliant, in thought. His decision in *Commonwealth v. Caton* (1782) was an early and significant defense of judicial review. He published many of his more important opinions in *Decisions of Cases in Virginia by the High Court of Chancery* (1795). A republican nationalist of the school of James Madison and Jefferson, he was a brief participant in the Constitutional Convention of 1787.

Wythe was equally important as a law teacher. Recognizing the need for the formal training of lawyers, Jefferson and others established at the College of William and Mary the first professorship of law in the United States with Wythe as the professor. During his tenure at the college, from 1779 to 1790, he taught and trained John Marshall, James Monroe, Henry Clay, and other leading Virginia lawyers and jurists. His methods permanently influenced American legal education.

Wythe was poisoned by an inheritance-seeking grandnephew and died in Richmond on June 8, 1806, but not before disinheriting the youth, who was acquitted because the chief witness was a black cook whose testimony was inadmissible at that time.

A. C. SYLVESTER, CAMBRIDGE, ENGLAND

The development of the letter X is illustrated in the chart above, beginning with the early North Semitic letter. The evolution of the majuscule (capital) is shown at top; that of the minuscule (lowercase) at bottom.

χ, eks, the 24th letter of the English alphabet, corresponding to the 21st of the Latin, from which its position and shape are derived (the increase in number being due merely to the differentiation of *i* and *j*, and of *u*, *v*, and *w* in the English alphabet). Its name *ix* or *ex* is also of Latin origin. The combination of consonants written *x*, namely *ks*, does not exist initially in English; those words which show it are all foreign and, with hardly an exception, Greek (for example, *xylophone*). *Xavier* is a Spanish local name, and *exes* simply the Greek rendering of the Persian word *hšayathiya* (king). The Romans could not pronounce the Greek name (*xei*) of the letter, but substituted *ix* for it, not so much by inverting the order of the sounds in the name as by prefixing a vowel and then dropping the final vowel. The symbol appears in the Etruscan alphabet also, but only in *abecedaria* (which nevertheless have *Ϟ*, *samekh*, in addition). Etruscan inscriptions also have *X* with the numerical value of 10, and it is possible that this use in Latin was taken over from the Etruscans, the upper part (*V*) indicating one half the amount—perhaps suggested by a rude sketch of the hand with fingers and thumb outstretched. On the other hand, the *V* symbol (5) may have been the older, and the use of *X* for 10 may have been inspired by the apparently doubled *V*.

In modern times in algebra *x* is used to designate an unknown quantity, and hence also in the sciences (as in *X-rays*), though the concept is far from modern. As an abbreviation *X* is used sometimes in the sense of "extra"; for example, it is used for the additional (or extra) decretals of Gregory IX. It is also used for the older Christus-symbol (Ϟ) as an abbreviation of *Christ*—in *Xmas*, and in Greek inscriptions for *chilio*, "thousand(s)."

The use of *X* with the phonetic value *ks* is proper to the western subdivision of the ancient Greek alphabet that came to be adopted in Italy. Hence its appearance in modern western European alphabets with the same value, whereas in the Attic (eastern) Greek alphabet *X* (χ) has the value of an aspirated *k* (*kh* or *ch*), for which the western had *ψ*. In Attic *x* is written ξ (*ξ*), and this is represented by the variant Ϟ of the Chalcidian *abecedaria*, which is also the Palestinian Ϟ, the Moabite Ϟ, Cretan and Phoenician Ϟ, square Hebrew Ϟ. Its name is *sāmekh*, "fish," and in the proto-Sinaitic texts a drawing of a fish has been identified with the Canaanitish Ϟ. Another view interprets *sāmekh* as "prop" (?), which is

closer to the hieroglyphic Ϟ (subsequently Ϟ). In any event, the Semitic value is *s*, and in early Greek inscriptions not only does Ϟ appear beside Ι (*ξ*) for *sd* (or *zd*), just as in early Latin *z* means *s* or *ss*, but also *xo* and *xo* appear for *x*, a fact which shows that *sāmekh* was felt to be inadequate. A few early Ionic inscriptions have a symbol Ϟ or Ϟ (*h*) used in combination with *s* to signify *x*. If this had been confused with *sāmekh*, it is easy to see how the latter, used alone, might come to have the value *x*. However, evidence is lacking to prove this intermediate stage, and *X* (in some Greek alphabets Ϟ) has been held to be derived from Ϟ; in the Messapic alphabet *X* or Ϟ actually has the value *s*, not *x*. It is, nevertheless, noteworthy (1) that the combination *-ks-* often becomes *-khs-* and *-hs-* (Gothic *wahsjan* has *-hs-* from an older *-ks-*; compare *ahsa* beside Latin *axis*), and this becomes *ch* or *h* (Welsh *achel*, "axis"; *chwech*, "six"); (2) that another development of the same combination is *-ss-* or *s-*, as in Irish *dess* beside Latin *dexter*, "right-handed"; *mas* beside Latin *mox*, "soon," like Vulgar Latin *dester* (Italian *destro*, French *destrier*), and Provençal *cis(s)ir* from Latin *exire*. In the later Greek numerical use of alphabetic symbols ξ means "sixty," and this appears also in the Cyrillic Old Church Slavonic. The Greek name *xei* was modeled on *pei* (π), taken from the Semitic *pē*. In Old English runes *Y*, later *ƿ*, appears instead of the older Latin *x*; its name was *colhs*, but the meaning, "elk" (?), and derivation (perhaps from *Y*, *z*) are dubious.

Nearly all modern English words containing the prefix *ex-* were borrowed from French, and show a curious variation of pronunciation; thus *x* is *gz* before accented vowels (as in *examine*, *exert*), but *ks* after accented vowels (as *execute*, *exit*). In Latin *x* was always *ks*, but this became *gz* in early French, and the French pronunciation was borrowed into English. Subsequently the influence of the normal English pronunciation of *ex-* in Latin words influenced that of most words in which the accent was thrown back onto the first syllable, though the old pronunciation still survives beside the new in a few words (*exile*, *exigence*), and some have both pronunciations even before accented vowels (*exhale*, *exhilarate*, *exude*). In Old English, especially in late West Saxon, metathesis of *xx* to *cs*, written *x*, is not uncommon (for example, *axe*, "ashes," *axian*, "ask"). The final combination *-ks* is stable (*vox*, *wax*, *axe*).

XANTHIAN MARBLES. See **XANTHUS** (city).

XANTHIPPE, zăn-tîp'ê, or **XANTIPPE**, ancient Greek matron: fl. 400 B.C. She was the wife of Socrates, the Athenian philosopher, to whom she bore a son. Her name has become proverbial for a scolding and nagging wife. Socrates is reported to have said that he lived with a shrew, as horsemen with spirited horses, "but, just as, when they have mastered these, they can cope easily with other horses, so I in Xanthippe's society shall learn to adapt myself to other persons" (Diogenes Laertius, *Lives and Opinions of Eminent Philosophers*, book 2, chap. 5, sect. 37).

P. R. COLEMAN-NORTON

XANTHIUM. See **COCKLEBUR**.

XANTHOPHYLLS, zăn'thê-fîlz, ubiquitous or nearly ubiquitous yellow and red pigments of higher and lower plants, like the related carotenes. Also like the carotenes, the xanthophylls possess 40 carbon atoms. However, the carotenes, such as α - and β -carotene, and lycopene, the principal pigment of the tomato, are hydrocarbons, and typically soluble in petroleum ether; while the xanthophylls, oxygen-containing derivatives of the carotenes, are typically insoluble in petroleum ether, but soluble in alcoholic solutions. Xanthophyll, like carotene, is a group name, and includes many individual chemical compounds. The major constituent of the xanthophylls of leaves is lutein, which has the structure of α -carotene, containing in addition an -OH or hydroxyl group in each terminal ring, as shown in the following formula:

Lutein occurs not only in leaves but also in egg yolk, in which it is the principal yellow coloring matter. Further leaf xanthophylls include zeaxanthin, a β -carotene containing two hydroxyl groups; lycoxanthin, an oxidized lycopene containing one hydroxyl group; and lycophyll, an oxidized lycopene containing two hydroxyl groups. In all of these oxidation products, the hydroxyl groups occupy the same positions in the structure, namely the so-called three positions. Further and rarer xanthophylls contain hydroxyl groups in other positions.

The oxygenated xanthophylls include not only hydroxyl derivatives of the carotenes, but also esters, ketones, and hydroxyketones. Thus, rhodoxanthin, which is the red pigment of the berries of *Taxus baccata*, is a diketoxanthophyll, while the red pigment of the pepper *Capsicum annuum* consists of capsanthin and capsorubin, the latter containing two hydroxyl and two keto groups. Xanthophylls have no known physiological role in plants, although the bright coloration which they confer upon plant tissue may possess ecological and selective value.

XANTHUS, zăn'thəs, Greek historian: b. Sardis, Lydia, Asia Minor, c. 499 B.C.; d. after 424 B.C. He was the reputed author of *Lydiaka* (*Lydian Affairs*) in four books—a miscellany of history, folklore, romance, genealogy, botany—which later ancient authors excerpted extensively. Xanthus also wrote a work on the Magian religion as well as a study of the life of the philosopher Empedocles. Of these treatises only 33 fragments survive.

XANTHUS, ancient city, Lycia, Asia Minor, located on the west bank of the river Xanthus (modern Koca) and about nine miles from its mouth. Xanthus was Lycia's most celebrated community. Its chief claim to fame is that its citizens twice preferred to perish in its ruins rather than surrender to its besiegers: Persians about 545 B.C. and Romans in 42 B.C. Xanthus did not survive the second catastrophe. Its well-preserved ruins near Günük include temples, triumphal arches, a theater, walls, and tombs. The site was discovered in 1838 by Sir Charles Fellows, who transported during 1842–1844 a large collection of its marbles, chiefly sepulchral, to its present location in the British Museum in London. The collection is known as the Xanthian Marbles.

P. R. COLEMAN-NORTON

XANTHUS, ancient name of two rivers in Asia Minor.

(1) Now called **KOCA**, in ancient Lycia. Its source is in Mount Taurus on the Pisidian border of Lycia. About 75 miles long, it flows as a navigable river southwestward toward the Mediterranean Sea, which it enters about 8 miles south of ancient Xanthus.

(2) Called **SCAMANDER** by men, but Xanthus by deities, now called **KUCUK MENDERES** (see **MAEANDER RIVER**), in ancient Troas, near Troy (now Hisarlik). Xanthus is frequently mentioned in Homer's *Iliad*.

P. R. COLEMAN-NORTON

XANTHUS AND BALIUS, zăn'thəs, bäl'i-as, in classical mythology, Achilles' chariot horses. They were immortal and swift steeds, offspring of Zephyrus (West Wind) and the harpy Podarge. Toward the end of the Trojan War their master, on re-entering the fray, rebuked them for not bringing back the body of Patroclus, Achilles' friend, who had driven them into battle and then was killed. Xanthus, suddenly endowed with speech, replied that they would return Achilles safely, but that Achilles would die soon after.

not by his horses' fault, but by fate (Homer, *Iliad*, book 19, vss. 400-410).

XAVIER, SAINT Francis. See FRANCIS XAVIER, SAINT.

XAVIER UNIVERSITY, zá'ví-ar, a Roman Catholic institution of higher education, located in Cincinnati, Ohio. It is the oldest Catholic institution of higher learning in the area once designated as the Northwest Territory. It was founded in 1831 as the Athenaeum, and nine years later passed under the control of the Society of Jesus (Jesuits). The university has five units: College of Arts and Sciences (founded 1831) and the College of Business Administration (1961), both for men; Evening College (1911), coeducational; Milford College (1925; for students in training to become Jesuits); and the Graduate School (1948), coeducational. All units except the Milford College (at Milford, Ohio) are located on the 65-acre campus in the geographical center of greater Cincinnati. The style of architecture of Xavier's modern buildings is typically Tudor. Enrollment is in excess of 6,000 students. School colors are blue and white; the rally song is *Xavier for Aye*; the athletic teams are known as "The Musketeers."

EDWARD P. VONDERHAAR.

XAVIER UNIVERSITY OF LOUISIANA, a co-educational Roman Catholic institution located in New Orleans, La., and founded in 1925 by the Sisters of the Blessed Sacrament for Indians and colored people. It is composed of the College of Arts and Sciences, the College of Pharmacy, and the Graduate School. Originally situated near the Garden District of New Orleans, the university moved in 1932 to its present site at Palmetto and Pine streets. The campus, covering 10 square blocks, includes the administration and main classroom building and the convent—both of which are constructed in the Gothic style and in Indiana limestone—library, men's dormitory, women's dormitories, gymnasium, science building, music building, and a \$500,000 glass-and-concrete Student Center. The university's average enrollment is approximately 1,350 students. The school colors are gold and white, and the school song is *In the Mississippi Valley*.

SISTER MARY JOSEPHINA, S.B.S.,
President.

X CHROMOSOME. See CHROMOSOME.

XEBEC, zé'bék, a small three-masted vessel, employed in the Mediterranean, distinguished from other European vessels by the great projection of the prow and stern beyond the cutwater and stempost. In this respect it resembles the felucca, from which it differs in having the foremast square-rigged.

XENIA, zē'n'ya, city, Ohio, seat of Greene County, 15 miles east of Dayton, near the Little Miami River. It is a trading center for one of the state's principal agricultural areas, producing hogs, dairy cattle, feeder cattle, sheep, and such crops as fruits, grains, feed, and some tobacco. Industry within the city is varied; important manufactures include rope and twine, furniture, monuments, metal castings, synthetic rubber goods, plastics, electrical equipment, paints, and foodstuffs. There

is an airport for chartered planes. Wilberforce University is located nearby. Xenia (from the Greek word for hospitality) was founded in 1803, the year Ohio achieved statehood; it was incorporated in 1817 and became a city in 1834. The community soon attracted many pioneer industries, such as flour mills and sawmills, and experienced further economic development with the coming of the railroad in 1843. In 1918 the city of Xenia became one of the first cities to adopt the commission-manager form of government. Population: 24,664.

XENIA AND METAXENIA, zē'n'ya, mēt'a-zē-n'ya. The term "xenia" was proposed by Wilhelm O. Focke in 1881 for the direct effect of foreign pollen on any part of a plant. Those examples best known are the changes produced in the size, shape, and color of seeds, such as the mixture of blue and yellow kernels of corn on the same cob when a yellow variety is pollinated by a blue variety. Such changes involve chiefly the endosperm. The occurrence of xenia in seeds was explained in 1898 by Sergei Nawashin when he discovered that pollen may have an effect on the genetic composition of both embryo and endosperm.

Early reports on the direct effect of pollen on tissue other than embryo and endosperm as indicated by size, shape, and color of fruit were not convincing because of inadequate or contradictory data; confusion among different factors involved, such as the presence, absence, number, or imperfect development of seeds; and physiological influences, such as number of leaves per fruit. As a consequence, xenia became restricted in most usage to the direct effect of pollen on the embryo and endosperm. A series of experiments with dates begun in 1925 produced spectacular evidence that pollen may affect not only the size, shape, and color of the seed, but also the size and the time of ripening of the fruit. "To designate the action of the male parent on tissues of the mother plant outside the embryo and endosperm," Walter T. Swingle coined the word "metaxenia." It was Swingle who suggested the theory that the embryo or the endosperm, or possibly both, secrete hormones that influence the development of the ovarian tissues of the mother plant.

Metaxenia has since been shown to occur in a number of plants, including apples (size, shape, and color) and cotton (boll maturity, length of lint). Failure to demonstrate metaxenia often may be due not only to difficulties in obtaining evidence but even more to the lack of sufficient genetic diversity among the pollen parents compared.

United States Department of Agriculture

XENOCLES, zī-nōk'lēz, name of two ancient Athenian tragic poets.

XENOCLES THE ELDER (fl. 415 B.C.) defeated Euripides in a dramatic festival with his tetralogy of *Oedipus*, *Lycaon*, *Bacchae*, and *Athamas*, of which nothing remains. Ancient authors considered his poetry rather poor and condemned the construction of his plots, wherein complicated devices and sudden surprises produced the result which the natural development of the drama should have effected.

XENOCLES THE YOUNGER (fl. 4th century B.C.)

was mentioned in antiquity only to distinguish him from Xenocles the Elder, his grandfather. Unfortunately, not even the title of any of his tragedies survives.

XENOCRATES, zī-nōk'ra-tēz, Greek philosopher: b. Chalcedon, Bithynia, Asia Minor, 396 B.C.; d. Athens, Greece, 314 B.C. About the year 380 he migrated to Athens, where he studied philosophy under Plato and eventually presided over Plato's Academy from 339 until his death. In logic he tried to exhibit mathematics as mediating between knowledge and perception. He failed to grasp the idealism underlying Plato's ontology and, infected with Pythagoreanism, took arithmetical unity and plurality for his principles in physics and then identified ideal numbers with arithmetical numbers. The titles of over 75 treatises written by him clearly indicate that he accorded especial attention to ethics. In this philosophical area Xenocrates was most concerned that Plato's teachings should be given a more direct applicability to life.

His contemporaries respected Xenocrates for his integrity, dignity, and courtesy. Modern scholars regard him as the most faithful of Plato's followers, as the typical representative of the Old Academy, and as a brilliant teacher rather than an original thinker.

XENON, zē'nōn (symbol Xe), chemical element number 54, and the fifth member of the family of inert gases. Xenon is a colorless, odorless, and tasteless gas under ordinary conditions, and constitutes 0.086 parts per million by volume of dry air. Traces are also found in certain minerals. The density of the gas under standard conditions is 5.8992 grams per liter. Xenon, made up of 9 stable isotopes ranging in mass number from 124 through 136, has an atomic weight of 131.30. The element was discovered in England in 1898 jointly by Sir William Ramsey and Morris W. Travers, who isolated it by fractional distillation from a sample of krypton, and identified it as a new element by observing hitherto unknown lines in its emission spectrum.

Xenon has a number of commercial and scientific applications, among which may be mentioned its use in flash lamps for high speed photography, and its use in liquefied form in the particle detectors called bubble chambers, in which certain types of nuclear experiments are best performed with use of an extremely dense liquid. Xenon is obtained commercially by liquefaction and distillation of air, followed by special purification processes.

KENNETH W. PERKINS

XENOPHANES, zī-nōf'a-nēz, Greek philosopher and poet: b. Colophon, Ionia, Asia Minor, c. 590 B.C.; d. probably in Sicily, c. 478 B.C. An exile or a fugitive from Colophon when 25 years old, he lived mostly in southern Italy and Sicily. Xenophanes' philosophy, such as it is, was embodied in his poems, principally elegies and satires on various subjects, recited at festivals. Some 40 fragments remain.

Xenophanes ridiculed the popular religious notions of the Greeks, who believed in a plurality

of deities in human form and accepted the traditional tales of the divinities' vices. He held that that which is divine can only be one, that there can be only one best, and, therefore, that God must be conceived as one. Xenophanes was more of a pantheist than a monotheist, for he identified God with the world and considered God as a sentient being, though without organs of sense, unchangeable, undivided, unmoved, undisturbed, passionless, and governing the world through thought. Among the testimonies to Xenophanes' philosophy his attack on the Pythagorean doctrine of transmigration of souls is perhaps the most prominent.

Although ancient authors considered Xenophanes the founder of the Eleatic school of philosophy, most modern scholars suggest that he was rather its forerunner, whose seeds of thought were transformed into philosophical principles by Parmenides, the real creator of the sect. It was with Xenophanes, who was primarily a critical thinker rather than a creative philosopher, that the Western quarrel between philosophy and religion originated.

XENOPHON, zēn'a-fūn, Greek historian, essayist, and soldier: b. Athens, Greece, c. 430 B.C.; d. Corinth, c. 354 B.C. During the latter part of the Peloponnesian War (431–404 B.C.), he both served in the Athenian cavalry and studied philosophy under Socrates. At the war's end Xenophon probably was disheartened by the destruction of the Delian League (q.v.), controlled by Athens, and perhaps was disgusted with the deterioration of Athenian democracy. However this may have been, in 401 he accepted an invitation to join, as an officer of Greek mercenaries, the army of Cyrus the Younger, who desired to dethrone his older brother Artaxerxes II Mnemon, king of Persia. Xenophon accompanied the expedition from Sardis in Asia Minor, fought at Cunaxa (near Babylon) in Persia, where Cyrus was killed and his cause collapsed, and then played a prominent part in conducting the retreat of over 12,000 Greek survivors from Cunaxa to Chrysopolis on the Sea of Marmara, which less than 6,000 Greeks reached in 399 after marching almost 1,300 miles, mostly through mountainous terrain inhabited by hostile tribes. Most modern military historians consider Xenophon, who in this perilous operation evinced consummate qualities of leadership and employed supreme tactical ability, as the inventor of retreat tactics still valid in warfare amid mountains.

After he had heard, while still in Asia, that Athens had banished him (probably because of his Spartan sympathy and his Persian friendship—both Sparta occasionally and Persia traditionally being hostile to Athens), Xenophon served with the Spartan expeditionary forces warring against Persian satraps in Asia Minor (399–394) and then returned to Greece. There he perhaps participated in the Spartan victory over Thebans and Athenians at Coronea in Boeotia (394). King Agesilaus II of Sparta then presented Xenophon with an estate at Scillus (near Olympia) in Elis, where he devoted himself to farming, hunting, entertaining, and writing. The Elean recovery of Scillus from Sparta (c. 371) induced Xenophon to move to Corinth. Although Athens restored Xenophon's citizenship (c. 369), it is uncertain whether

later he visited Athens, but it is known that he sent his two sons thither to serve in the Athenian cavalry.

His Writings.—Xenophon wrote probably most of his known 14 works during his two decades at Scillus. The most famous is *Kyrou anabasis* (Lat. *Cyri anabasis*; Eng. *Cyrus' Anabasis* or, more simply, *Anabasis*, q.v.), in seven books, which vividly describes Cyrus' campaign and the Greeks' retreat from Cunaxa through Persia and Asia Minor. *Hellenika* (Lat. *Hellenica*; Eng. *Greek Affairs*), in seven books, relates the contemporary history of Greece (411–362 B.C.) and displays pro-Spartan partiality. His most finished treatise is *Kyrou paideia* (Lat. *Cyropaedia*; Eng. *Cyrus' Education*), in eight books, which is an idealized biography of Cyrus the Elder (Cyrus the Great; r. 550–529 B.C.), the founder of the Persian monarchy. It has little value as authentic history and it contains numerous romantic touches, but it offers many practical suggestions for educating youths and it presents Xenophon's model of a wise and beneficent ruler.

The Bettmann Archive

Xenophon

Lakedaimonion politeia (*Polity of the Lacedaemonians*) lauds Spartan institutions. Agesilaos, a panegyric of King Agesilaos II of Sparta, is among the earliest Greek biographies. *Hipparchikos* (Lat. *Hipparchicus*; Eng. *Cavalry Commander*) describes the duties of a commander of cavalry and presents methods for improving the contemporary use of cavalry. *Peri hippikes* (*On Horsemanship*) supplements *Hipparchikos* and is the oldest complete manual on this subject still extant. *Kynegetikos* (Lat. *Cynegeticus*; Eng. *Fond of Hunting*) praises hunting, discusses the breeding and the training of dogs, particularly of hunting dogs, and suggests various ways of capturing game. *Hieron* is a fictitious conversation

between Hiero I, tyrant (king) of Syracuse in Sicily, and the poet Simonides of Ceos, who sojourned at Syracuse in 476 B.C. The dialogue discusses the comparative happiness of a despot and a private citizen and how an autocrat can secure his subjects' affection.

Symposion (Lat. *Symposium*; Eng. *Banquet*) depicts an amusing and imaginary wine party, whereat Socrates and some of his followers discourse on love and friendship. *Oikonomikos* (Lat. *Oeconomicus*; Eng. *House Manager*) is a contrived discussion between Socrates and his disciple Critobulus on management of a rural estate. It lauds agriculture; describes the duties of the householder, his wife, and their servants; contains practical advice for arranging rooms and their contents; and presents Xenophon's ideas about the good life in the country. *Poroi e peri prosodon* (*Ways and Means or On Revenues*) suggests methods for improvement of Athenian public finance, such as increasing the number of resident aliens engaged in commerce and managing efficiently the state-operated silver mines. *Apologia Socratous* (*Socrates' Apology*) shows why Socrates failed to make a better defense of himself at his trial in 399 B.C.

Apomnemoneumata Socratous (Lat. *Socratis memorabilia*; Eng. *Memorable Facts About Socrates*), in four books, is an interpretation of the philosopher's life and teaching. It defends Socrates and presents many convincing reminiscences of and anecdotes about his teacher. Much scholarly debate still surrounds Xenophon's trustworthiness compared to Plato's in respect to the real Socrates. Certainly Xenophon is seen to be inferior to Plato in comprehending the difficult points of Socrates' doctrines. But Xenophon surpasses Plato in presenting a portrait of Socrates the teacher as opposed to Socrates the thinker. It is an entirely practical work, such as Xenophon was qualified to compose. That Xenophon wrote *Athenaion politeia* (*Polity of the Athenians*), an oligarch's disparaging discussion of the Athenian democracy, was doubted even in antiquity, and by modern scholars has been adjudged to be the work of an unknown author.

Xenophon, whom later Greeks called the "Attic Bee" because of his literary industry, writes mostly in clear and simple, yet sometimes elegant and rhetorical, language. His chief faults are tedious repetition of trite thoughts, persistent moralizing and insistent didacticism, obvious borrowing from earlier authors, and insufficient understanding of economics, history, and philosophy. But these failings perhaps are outweighed by his strong humanity, simple piety, admirable versatility in literary genres, extraordinary insight into military tactics, and sympathetic interests.

P. R. COLEMAN-NORTON,
Princeton University.

XENOPHON OF EPHEBUS. See EPHESIACA.

XENOTIME, zén'a-tím (formula YPO.), a mineral crystallizing in the tetragonal system in short prismatic crystals. The hardness is 4–5, and the

specific gravity 4.4–5.1. The luster varies from vitreous to resinous, and it is transparent to opaque. It resembles zircon (ZrSiO_4) in color and crystal form, and has a similar crystal structure, but is distinguished from zircon by a lower hardness and a good prismatic cleavage.

Xenotime occurs as an accessory mineral in granites and syenites, and crystals may occur in granite pegmatites. It is usually found in detrital deposits, and is mined in placer deposits in North Carolina, Georgia, Alabama, Brazil, Madagascar, and New Zealand. It occurs also in pegmatites in Norway, Sweden, and Japan. Xenotime is a commercial source of yttrium and other rare earth elements, and in placer deposits may be associated with more valuable thorium minerals.

LEWIS S. RAMSDELL.

XERARCH SUCCESSION, zē'rärk sək-sēsh'ən. Plants and associated animals invariably invade unoccupied habitats where their establishment produces environmental changes that permit still other organisms to come in, superseding each other in a predictable pattern over a period of time. The sequence of interrelated environmental and biotic changes, known as succession, varies in direction and rate largely in response to moisture conditions. Succession initiated in dry habitats is distinguished as "xerarch" (Gr. *xeros*, dry, and *arche*, beginning), and that on wet sites as "hydrarch."

An extreme xerarch succession occurs on bare rock. Certain mosses and lichens are able to attach themselves and survive repeated desiccation between periods of precipitation. The tiny patches which slowly emerge catch dust and plant remains upon which other mosses and coarse lichens can grow. Now a mat begins to form which may become thick enough to support herbaceous seed plants and, later, drought-resistant shrubs or even, ultimately, trees. As the mat thickens and succession progresses at the center, the pioneers will have migrated outward around the periphery, and the sequence of growth forms which followed the pioneers will show in narrow, irregular zones from the margin inward. The slow process is always subject to interruption by disturbance, and it progresses only as moisture conditions improve with thickening and expansion of the mat.

XERES DE LA FRONTERA. See JEREZ.

XEROGRAPHY, zī-rōg' rə-fē, an electrostatic reproduction process, invented in 1937 by Chester F. Carlson and developed by the Battelle Memorial Institute and The Haloid Company (now Xerox Corporation). A xerographic plate consists of an electrically conductive back with a photoconductive surface. This plate, electrostatically charged, will, when exposed to an image, discharge more in the bright areas and retain a latent electrostatic image. Such an image can be made visible by depositing electrically charged particles of appropriate color, or by other means.

A powder image on a reusable photoconductor, such as selenium, is electrostatically or adhesively transferred to a final support such as paper and stabilized by heat or solvent vapors. Image effects range from line copy through X-ray images to continuous-tone photographs. The selenium plate uses a vitreous form that is primarily sensitive to blue-green light, with a photographic speed of ASA 4. Panchromatic plates of

faster speed have been made. The other common form of photoconductor is a suspension of zinc oxide crystals in plastic, usually coated on paper made hygroscopic by various additives.

In "xerotyping," a permanent insulating image is charged, xerographically developed, and the powder image transferred to paper at speeds up to 1,200 feet per minute.

How xerography works. (1) Surface of specially coated plate is electrically charged as it passes under wires. (2) Coating of plate charged with positive electricity. (3) Copy (E) is projected through lens in camera. Plus marks show projected image with positive charges. Positive charges disappear in areas exposed to light as shown by white space. (4) A negatively charged powder adheres to positively charged image. (5) After powder treatment (4) a sheet of paper is placed over plate, and receives positive charge. (6) Positively charged paper attracts powder from plate, forming direct positive image. (7) Print is heated for a few seconds to fuse powder and form permanent print.

High-contrast xerography can be used to copy documents, microfilm (negative or positive),

maps, cathode-ray images, and galvanometer recording, and to make lantern slides or printed electric circuits. Paper or metal plates for offset lithography can be made, as can masters for spirit duplicators (hectograph).

HARRY L. GAGE.

XEROPHTHALMIA, zê-rôf-thál'mí-ə, or **XEROSIS**, zî-rô'sis, a degenerative condition with characteristic dryness of the conjunctiva and cornea of the human eye. The dryness is not due to diminution of the tear fluid, but rather to tissue changes. Normally the conjunctiva is moistened by its own secretion from the accessory lacrimal glands of Wolfring and Krause, also from the secretion of the goblet cells; therefore removal of the main lacrimal gland does not lead necessarily to xerophthalmia. But even in the presence of copious lacrimal secretion, degenerative processes, either of local or systemic origin may cause xerophthalmia. Xerophthalmia or xerosis is not a disease, but is a symptom and may be the sequel of local disease, or a symptom of general disease.

Local Disease.—In cicatricial (scarring) degeneration of the conjunctiva due to trachoma, pemphigus, extensive burns or other conditions, the subconjunctival tissue is replaced by scar tissue, thus eliminating the self-lubricating capability of the conjunctiva. Also, exposure of the mucous membrane (conjunctiva) constantly to air, as in lagophthalmos (paralysis of the eyelid muscles), will cause xerophthalmia, which with the ensuing tissue changes (keratinization) of the mucous membrane will endanger the health of the entire anterior segment of the eye.

General Disease.—Xerophthalmia is part of a complex of symptoms resulting from malnutrition in general and vitamin A deficiency in particular. Characteristic changes involve the mucous membranes and the epithelium of the skin. The medullated nerve fibers are also undergoing degeneration, both centrally and peripherally.

The eye symptoms vary from mild dryness (xerosis) of the conjunctiva, with mild night blindness, to severe dryness and tissue changes in the conjunctiva and cornea. Night blindness might be severe. In advanced stages of xerophthalmia the cornea may be destroyed by keratomalacia (severe degeneration of corneal tissues), followed by corneal ulcers. The inner eye is then open to severe infections which may involve and

destroy the entire eyeball (panophthalmitis). Lens opacities (cataract) have been reported in some of the cases where the course of the disease was prolonged. Early symptoms in the eye include lack of luster and wrinkling of the conjunctiva. Small white foamy patches, first oval, later triangular in shape, appear on the conjunctiva, especially on the temporal side in the area which is exposed to air; they are called Bitot's spots. Tear fluid will not wet these patches, which are usually found in both eyes. They are named after the French physician, Pierre Bitot, who gave the best-known description of the condition in modern times (1863). The symptom complex of which xerophthalmia is a part has been well known since ancient times. It was accurately described by Aulus Cornelius Celsus (about 25 A.D.) and its description can be found in an Egyptian papyrus from the 19th century B.C. In exceptional cases, persons in robust health will exhibit the symptoms of xerophthalmia, but usually it is seen only in patients who have mild to severe malnutrition.

XEROPHYTE, zê-rə-fīt, any of numerous plants which can endure recurrent drought by means of special structural and functional adaptations, notably by a remarkable resistance to wilting. Although many xerophytes are found in deserts (comprising about one fifth of the earth's surface), they are not confined to such areas. Algae, fungi, lichens, and mosses, growing on tree barks or rocks, are as typical xerophytes as are the well-known members of the predominantly American cactus family (Cactaceae) and certain Old World (African) members of the spurge family (Euphorbiaceae). Probably all xerophytes have arisen independently of mesophytes (plants growing under less extreme conditions), and are more numerous and diversified than hydrophytes (aquatic plants).

Three general types of xerophytes can be recognized:

(1) Ephemeral annuals. These plants, which are small and numerous in arid regions, survive the long dry season as seeds after completing their life cycles during the few (four to six) rainy weeks.

Xerophytes, left to right: Lichens are developed through the effect on each other of two different kinds of plants that grow together. The plant called hen and chickens increases by sending out small buds.

T. H. Everett; Roche

(2) Succulents. These plants are equipped with water-storage tissue (fleshy roots, stems, or leaves) in which they accumulate large amounts of water during the rainy season. The cells of this tissue swell up a great deal. The shallow root system of cacti enables them to accumulate the minute quantities of water penetrating the upper inches of soil. In addition to other protective devices, succulents are able to keep their stomata closed during the daytime and open at night, thus considerably reducing further loss of water. They may lose 25 percent or more of their stored water and remain alive. Succulence is retained by limited use of stored water, since transpiration rates are generally very low when outside water is not available. Included in this group of plants, many of which are frequently seen in cultivation—are such plants as cacti, century plant, aloes, and stapelias.

(3) Nonsucculent perennials. This group is able to endure periods of permanent wilting; such periods are always short in the case of most woody plants, but may last months or years in the case of grasses and other herbaceous plants. Outstanding adaptations of the nonsucculent perennials are: rapid elongation of the seedling taproots prior to desiccation of the soil; extensive root systems in proportion to shoot systems (mesquite roots may descend to a depth of 65 feet and alfalfa roots may reach 130 feet); minimum transpiration during permanent wilting, due to shedding of leaves; heavily cutinized or waxy evergreen leaves (as in sclerophylls, or hard-leaved plants); sunken or otherwise protected stomata; small leaf blades (microphyllous plants); vestigial leaves; loss of leaves, reduction in size of individual cells; high osmotic pressure; and endurance of desiccation, which is an adaptation that can be seen in the ability of algae, fungi, lichens, and mosses to remain alive in air-dry condition for considerable periods of time.

Although xerophytes in general are marked by many structural and functional adaptations, no combination of these is characteristic of all of them. Actually, each xerophyte maintains its water balance through its own combination of adaptive characters.

XEROTHERMIC THEORY, zê-rə-thûr'mîk thê'ə-rî. The term "xerothermic" was suggested in 1891 by the Swiss, John Isaak Briquet, to designate a climatic period occurring after retreat of the last great continental glaciers that had apparently been drier and warmer than that of the present. Louis Agassiz, in 1837, had presented evidence for the former existence of these glaciers over much of North America and Europe. Once this idea was accepted in the scientific world, the simplest explanation of climatic change was that there had been a gradual warming from glacial times down to the present. Ultimately, doubt was cast upon this assumption, however, by subsequent studies of animal fossils and the layers of plant remains that had accumulated in old lake beds as peat. In addition, there was an increasing knowledge of the present distribution of plant species.

Peat deposits are especially abundant in regions that once were covered by glacial ice. Beginning in 1842 much attention was given to the remains of vegetation found in successive layers of peat, especially in Scandinavia. As a result it became clear that above the lower layers of cold-

climate species, such as spruce, there were remains of other kinds, such as oak, mistletoe, and ivy, that thrive today in warmer regions than those in which they were laid down. Above them was a marked increase in the species that are found living under the present, evidently somewhat cooler climate. There was, however, a considerable amount of controversy, both as to the details of this record as well as to their method of interpretation.

The second reason for believing in a post-glacial xerothermic period (or periods) came from the presence of steppe plants surviving in parts of Europe whose characteristic climate favors forest rather than grassland. In North America there are similar areas of grassland, despite a forest climate such as that of Ohio. Henry Allan Gleason, in 1915, discussing the presence in Illinois of communities of arid-climate species, advanced the explanation that they were relict-surviving remnants of a type of vegetation much more abundant during a former drier and warmer phase of climate.

Impressive as these two lines of evidence were, debate continued. This is why the term "theory" has been employed, pending more positive proof. Supporting evidence became possible with the development, by the Swedish scientist Ernst J. Lennart von Post in 1915, of a technique known as pollen analysis. Since windblown pollen is deposited in large amounts in lake sediments, one can, by coring these sediments and identifying and counting the different kinds of pollen therein, get a useful notion of the trends in adjacent vegetation, and from it infer climatic changes.

Thus a typical deposit in the Great Lakes region of North America reveals the following sequence, from bottom to top, based upon the changing proportions of pollen: spruce, pine, hemlock, oak and hickory, beech and maple. Knowing the moisture and temperature requirements of these forest types, we can be reasonably certain that the intervals of pine and the later oak-hickory were relatively drier than the other three. They were also clearly warmer than the initial spruce interval and very probably warmer than the climate of today, as well as drier. Acceptance of this idea by geologists, at least so far as temperature is concerned, is reflected in their use of the term "altithermal" and the more recently coined "hypsihermal."

Willard Frank Libby's discovery of the method of dating organic materials by the use of radioactive carbon (see **RADIOCARBON DATING**) has made it possible to approximate the time scale of these changes, confining them to the last 10,000 years. Further refinements almost certainly will enable us to factor out the effects of moisture and temperature more closely than at present. Meanwhile, we know that the gradient from cool-moist (oceanic) to warm-dry (continental) climate in North America runs from northeast to southwest, and that climates in the past have shifted back and forth along the line of this diagonal. Plants and animals have changed their distribution accordingly, and so doubtless have the activities of prehistoric man.

XERXES I, zûr'xêz (called **THE GREAT**; Persian **KHSHAYARSHA**), king of Persia: d. Susa, Persia, 465 B.C.; r. 486-465 B.C. He was a son of Darius I

Hystaspis (Darius the Great) and Atossa, daughter of Cyrus the Great. He prepared (483–481) to execute his father's thwarted plan to conquer Greece by inducing Carthage to attempt the conquest of Sicily, held by colonial Greeks; by securing support from several mainland Greek city-states; and by assembling an enormous army and armada to invade Greece.

Although Greek tradition grossly exaggerated the Persian forces—which it set usually at 2,641,610 soldiers and sailors of more than 50 nationalities (excluding all sorts of camp followers) and 4,207 ships—yet the Persians definitely outnumbered the Greeks. Most modern scholars have produced estimates that reduce the effective Persian strength to an army of 180,000 soldiers and a naval force of 600 ships.

Xerxes mustered his army at Sardis in Asia Minor (480), crossed the Hellespont (Dardanelles) by a bridge of boats, and penetrated Greece as far as Thermopylae in Locris. His fleet anchored off Artemisium in Euboea. Persian victories at both places (480) led to the devastation of Attica and the destruction of Athens. After the Persian naval defeat off Salamis in the Saronic Gulf (480), Xerxes returned to Asia. His army was conquered at Plataea in Boeotia (479) on traditionally the same day that the rest of his fleet was routed off Mycale in Asia Minor.

Xerxes then seems to have surrendered himself to such debauchery that his subjects were disgusted, and his guards eventually murdered him in a palace intrigue.

The occasional identification of Xerxes with Ahasuerus in the Biblical books of Ezra and Esther is erroneous, as shown by chronological data.

XIMENIA, zī-mē'nī-ə, a pantropical genus of the plant family Olacaceae, consisting of approximately 10 species. However, some or all of the species may be merely variants of *X. americana*. Depending upon the environment, this species is a tree or shrub, usually with thorns in the axil of the leaves.

Ximения is a semiparasite, most frequently found throughout the tropics along the coast, but it may also occur inland. The wood is aromatic, close-grained, and yellow, and can be used as a substitute for sandalwood; hence one of its common names, false sandalwood. The bark yields tannin. Leaves are oblong to elliptic, alternate, and entire. The small, fragrant flowers grow in

axillary clusters. There are four petals, yellow to yellowish white in color, and densely hairy within. The fruit is yellowish and smooth, about one half to an inch long, with acid sweet pulp; before the fruit ripens it has an odor like that of oil of almonds. Prussic acid has been obtained from the ripened fruit. The single large seed contains an oil that can be used for soap making and lubrication.

Authorities differ as to whether the seeds are edible or are purgative. Some of the common names of the plant are hog plum (Florida); sea-side plum, ciruelillo, and limoncilla (Cuba); tal-lo wood, manzanillo (El Salvador, Honduras, and Guatemala); bedara laut malaya, citron de mer (French colonies); and ciruelo (Columbia and Cuba).

XINGU RIVER, shēng-gōō, river, Brazil, a principal right-hand tributary of the Amazon. Several streams rising in the Serra do Roncador, a range in central Mato Grosso State, combine to form the river, which flows north through Pará State and joins the Amazon delta at its head below Porto de Moz. Broken by falls and rapids, much of its course is unexplored. It is 1,230 miles (1,980 km) long, but only its lower 100 miles (160 km) is navigable.

XIPHILINUS, zī-fī'li-nūs, **Joannes**, name of two Greek clergymen:

(1) Patriarch of Constantinople (1064–1075), a native of Trabzon in Asia Minor, composed several constitutions on ecclesiastical matters and some orations of theological interest. He often is confused with his nephew (2).

(2) Monk in Constantinople (fl. 1075), also from Trabzon and nephew of the patriarch (1). He abridged books 36–80 of the *Roman History* of Dio Cassius. His somewhat careless abridgement omitted many important statements which Joannes Zonaras (fl. 1120), a later epitomizer, preserved. Each epitome is printed with Dio Cassius' work.

XOCHICALCO, sō-chī-kāl'kō, Mexico, an extensive archaeological site lying slightly southwest of Cuernavaca in the State of Morelos, regarded as belonging to the finest pre-Hispanic Mexican period. It dates from the 2d century B. C. to the 9th century A. D., and has some characteristics (especially a large ball court) which are similar to Maya ruins. Some workers think that it is, in fact, a Maya city later taken over by the Mexicans of the high plateau; others believe that it was a Toltec stronghold built to resist an Olmec invasion from the east. The chief pyramid is almost the only construction with relief sculpture, and the design shows the Quetzalcoatl (Feathered Serpent) motif. See also Mexico—*History*.

IRENE NICHOLSON
Author of "Conquest of Mexico"

XOCHIMILCO, sō-chī-mēl'kō, Mexico, a suburb of Mexico City, 10 miles (16 km) south of the center of the capital.

It is situated on the shores of Lake Xochimilco, one of the few areas of water remaining from the ancient highland lake district of the central plateau. In the ancient Nahuatl tongue the

name means "Place of Flowers"; but the conquering armies of Hernán Cortés, forced back from the causeways into the water as they fought the defending Aztecs (1520), must have found the name ironical. Here the Indians had long raised flowers, vegetables, and fruits on rafts called *chinamoas*, made of interwoven twigs and reeds covered with mud. In the course of time the roots of the plants became attached to the bottom of the shallow lake and fixed the rafts to the mud. Hence the modern epithet of "floating gardens," although the present-day appearance is rather of raised meadows intersected by canals lined with poplars, flowers, and other plants. The gardens are a popular picnic and boating site for tourists, both Mexican and foreign, who traverse the waterways in a variety of craft, especially in the canoes called *trajineras*. These boats, punted with long oars, are decorated with arches of flowers and usually contain at least one guitarist—all contributing to a festive scene which contrasts sharply with the surrounding slums. (Since Xochimilco is considered part of the Federal District, separate population figures are not announced.)

IRENE NICHOLSON.

XOCHIPILLI, sō-chī-pē'li, Nahuatl god of flowers and patron of games, dance, and sport. A particularly fine and much-reproduced statue in the National Museum of Mexico shows him seated cross-legged on an elaborately carved pedestal, with carvings of flowers and other symbols on his legs and chest. In a drawing in the *Codex Magliabecchiano* he is wearing an eagle headdress and is being borne on a flowery litter by two serfs, preceded by a singer and conch blower. An ancient feast was dedicated to him and his consort Xochiquetzal.

IRENE NICHOLSON.

X-RAY ASTRONOMY, eks'rā əs-tron'ə-mē, is the study of radiation from celestial objects at spectral wavelengths shorter than 100 angstroms. The earth's atmosphere permits only small amounts of X-radiation to penetrate to the surface, so such studies require observations to be made from rockets, satellites, and high-altitude balloons.

Different kinds of objects in space emit X-radiation, including the sun, some stars, and supernovae. There are many unidentified sources and also a diffuse background that may be associated with radiation from other galaxies. The solar X-radiation appears to be of two kinds: a quasi-steady background and transient bursts associated with solar flares. Solar X-rays play an important part in the formation of the earth's ionosphere.

A rocket flight in 1962 detected a discrete source beyond the solar system for the first time, in the direction of the constellation Scorpius. Since then approximately 40 sources have been found. Most of them lie close to the plane of our galaxy and cluster in two regions—toward the galactic center and in the constellation Cygnus. Of the few sources that have been identified with visible objects, nearly all are associated with old supernovae. Different sources produce various kinds of X-rays, and some sources are variable in brightness. Determination of the nature of these sources must await information provided by larger observational instruments in more sophisticated space vehicles.

NANCY W. BOGESS

National Aeronautics and Space Administration

X-RAYS, eks'rāz, invisible, highly radiations similar in nature to visible much shorter wavelength, ranging from 10^{-7} (0.0000001) to 10^{-11} (0.0000000001) centimeter (cm). The designation "X"—for "unknown"—was used in 1895 by the discoverer of X-rays, Wilhelm Conrad Roentgen, because he was not then certain of their nature. X-rays, sometimes called roentgen rays, are now known to constitute a part of the electromagnetic spectrum of radiation, which also includes light waves, radio waves, ultraviolet waves, infrared or heat waves, microwaves, and gamma rays. X-rays are emitted from atoms as a result of specific rearrangements (energy transitions) of atomic electrons, and are produced in commercial X-ray tubes by bombarding a metallic target with a beam of high-velocity electrons. X-rays also occur in solar radiation and in other extraterrestrial radiations.

Roentgen found, among other things, that X-rays can penetrate matter opaque to visible light, and that, like visible light, they can activate photographic films and fluorescent screens. In 1912 other physicists discovered that crystalline solids (for example, metals and metallic salts) act as natural diffraction gratings for X-rays because X-ray wavelengths are of the order of magnitude of the dimensions of crystal lattices. A typical X-ray wavelength used in diffraction is 1 angstrom, or 10^{-8} cm, which is about $1/4000$ the wavelength of yellow light.

The medical applications of X-rays stem from the aforementioned discoveries by Roentgen, and from the fact that X-rays can destroy diseased body tissues, for example, tumors. To the physicist, the discovery of X-ray diffraction initiated the vital role played by X-rays in determining the structure of matter. The statement by Sir Arthur Eddington that, prior to the discovery and extensive application of X-ray diffraction, more was known about the interior of a star than about the interior of a table, was not an exaggeration.

1. Physics of X-Rays

Roentgen's Experiments.—X-rays were discovered by Roentgen, a professor of physics, on Nov. 8, 1895, at the Royal University of Würzburg in the German town of that name. Roentgen was experimenting with a primitive vacuum tube, then known variously as a Hittorf, a Crookes, or a Lenard tube, which was essentially a pear-shaped glass bulb provided with two metallic electrical-conducting terminals, called a cathode and an anode, hermetically sealed through the walls of the bulb. The cathode inside the bulb usually took the form of a small concave metal disk on the inner end of a metal stem passing through the neck of the pear-shaped bulb in a way not unlike the actual stem in the fruit. The other terminal, the anode, was usually sealed through the glass on one side of the pear at a point where a small teat-shaped projection for this purpose was blown into the glass wall.

The air pressure in such a bulb was reduced to the order of one millionth of normal atmospheric pressure by means of a vacuum pump. If the terminals of the tube were then connected to a source of high-voltage electric current, the cathode being connected to the negative terminal, the

Rotation radiation, a method of treating deep-seated cancer, requires the use of a 2 million-volt X-ray machine. The chair is rotated while the X-ray shoots its cell-destroying rays into the cancer. Surrounding tissues receive only a fraction of the radiation, while the center of the target gets the maximum effect.

American Cancer Society

glass walls of the tube, particularly at the opposite end of the bulb from the cathode, would be seen in the dark to emit a green fluorescent glow.

Roentgen was experimenting with such a tube completely enclosed in an opaque black cardboard box when he happened to notice that a fluorescent screen lying on the bench nearby and consisting of a piece of paper coated with the chemical substance barium platinocyanide, emitted light when and only when the tube inside the cardboard box was being supplied with the high-voltage electric current. After interposing various objects between the tube and the fluorescent screen, he concluded that its fluorescence must be produced by an invisible radiation traveling in straight paths from the tube to the screen. He showed that shadows could be cast in the fluorescent illumination of the screen by many objects, particularly heavy metals such as lead, which clearly absorbed the invisible rays much more completely than some lighter substances such as wood, cardboard, paper, or aluminum. He reported that "behind a bound book of about one thousand pages I saw the fluorescent screen light up brightly, the printer's ink offering scarcely a noticeable hindrance." The bones in his own hand cast shadows on the screen, while the rays passed easily through the flesh.

In the short space of scarcely more than two weeks, with very rudimentary equipment and with astonishing ingenuity, Roentgen performed a series of brilliant experiments that established, in broad outline at least, a large fraction of all the basic qualitative phenomena connected with X-rays.

News of the discovery spread through the world like wildfire, and applications were made almost immediately, especially in the realm of

medical diagnosis. In retrospect it is clear, however, that the discovery had far greater significance in the realm of physical research than in any of these immediate applications. It marked the opening of the era of what came to be called "modern physics," a period during which man's understanding, control, and use of the submicroscopic features of the world of nature—molecules, atoms, electrons, nuclei and their constituents—were developed to an astonishing degree. In this development of our physical knowledge of the world through research, the rays discovered by Roentgen have played one of the central roles.

Cathode Rays.—Rapidly moving electrons called cathode rays were already known to be produced in vacuum tubes such as Roentgen used, and in fact in Philipp Lenard's form of the tube a sufficiently thin window was provided to allow the cathode rays to stream out into the air. But Roentgen established that X-rays were also generated on the inner surfaces of the glass walls of the Hittorf or Crookes vacuum tube wherever these surfaces were bombarded with the cathode rays, the stream of rapidly moving electrons.

Provisionally we may conceive an electron as a small particle with a single unit of negative electric charge ($e = 4.803 \times 10^{-10}$ absolute electrostatic units) and with a mass of 9.1×10^{-28} gram. Electrons exist in huge numbers in all forms of matter. Swarms of them form the outer cloaks surrounding the nuclei of all atoms, where their characteristic motions, configurations, and energies of attachment account for most of the characteristic chemical and physical properties possessed by the chemical elements.

The electrons that bombarded the walls of Roentgen's tube are not to be confused with the X-rays they produced at their point of impact.

The electrons came chiefly from the cathode terminal of the Crookes tube. Most of the electrical energy supplied from the high-voltage generator to the terminals of the tube resulted in imparting high velocities (kinetic energy) to these electrons, and this energy was chiefly released as heat to the glass walls wherever they received the electron bombardment. Such heat could and frequently did melt the glass envelope. (Ordinarily only a fraction of 1 percent of the energy input is converted into X-rays.)

The source of supply of electrons in the earliest tubes was maintained by literally splashing them out of the cathode through bombardment of the latter by positive ions created in the residual gas of the tube by the electrical discharge itself. The operation of such gas-filled tubes was thus quite sensitive to small changes in the low residual gas pressure and therefore undesirably erratic. The X-ray tube, in consequence, passed through an evolution. At an early stage a refractory metal target was provided inside the vacuum envelope. The bulk of the cathode rays could strike against the surface of this target in a small, rather concentrated focal spot that had various provisions to remove the heat generated there by the bombardment. This focal spot then became the source from which the X-rays came. At another stage William David Coolidge found a way to dispense with the gas as a means of obtaining electrons from the cathode and to provide an electron discharge supplied by a cathode filament kept hot by a source of electric current.

X-Ray Spectra.—When the rapidly moving electrons are suddenly stopped by the metal target, the impact produces a mixture of X-rays of two distinct categories: (1) a line spectrum of X-rays characteristic of the material of which the target is composed, superposed upon (2) a continuous spectrum of X-rays in which all wavelengths or frequencies are present throughout. The latter range from wavelengths so long that they are absorbed completely in the glass walls or the exit window of the tube, to wavelengths having a well-defined upper limiting frequency (and lower limiting wavelength) beyond which there are no X-rays whatever at shorter wavelengths or higher frequencies. This upper frequency limit is called the quantum limit of the continuous X-ray spectrum.

As the preceding statements imply, X-rays exhibit all the characteristics of a transverse undulatory electromagnetic-wave phenomenon and indeed constitute a region of the general spectrum of electromagnetic radiations to which also belong the regions of radio waves, infrared radiation, visible light, ultraviolet light, and nuclear gamma rays. These various regions merge indistinguishably into one another, differing only in regard to one quality that may be described as the wavelength, λ , the frequency, ν , or the quantum energy, $h\nu$, of the radiation; for it has been found that whenever radiation interacts with matter it always does so in discrete amounts or bundles of energy called quanta. The wavelengths of X-rays range from about 10^{-9} to about 10^{-12} meter.

In all phenomena of wave propagation the product of the frequency, ν , by the wavelength, λ , gives the phase velocity of the radiation. The phase velocity of all electromagnetic radiation in free space (vacuum) is $c = 299,792$ kilometers per second. The quantum energy of the radiation is proportional to the frequency, and the ratio be-

tween quantum energy and frequency is Max Planck's famous universal constant, h . A convenient conversion rule follows from this: If we divide the constant number $12,398 \times 10^{-8}$ by either (1) quantum energy expressed in electron volts¹ or (2) wavelength, λ , expressed in centimeters, we obtain the other of these two quantities.

It soon became apparent that the continuous spectrum from X-ray tubes operating at higher applied voltages exhibited superior power of penetrating material screens. Such penetrating X-rays were called in the beginning "hard" X-rays. Less penetrating radiation was said to be "softer." These names have been retained in use, but it later came to be understood that "hard" radiation is more penetrating because it is shorter in wavelength (or higher in frequency or in quantum energy). It has been found that, save for certain important abrupt deviations (called absorption discontinuities), each atom of a given atomic number Z (see section 1. *Physics of X-Rays*—Moseley's Atomic Numbers) absorbs X-rays to an extent that varies approximately as the cube of the wavelength and as the fourth power of the atomic number.

Generation of the Continuous Spectrum.—To form a clearer picture of how the continuous X-ray spectrum is generated in the target, let us imagine the structure of this metal target on a scale of linear dimensions ten billion times natural size. Each atom would then be about the size of a moderately large room and the nucleus of the atom in the middle of that room would be about the size of a pinhead. In spite of the relatively tiny size of the nucleus, almost the entire mass ("weight") of the atom is nevertheless concentrated therein. With the increase in size we have envisioned, if our pinhead had the same matter density as actual nuclei possess it would have the fantastic mass of two tons, even if it were the lightest of all nuclei (a proton). If it were a tungsten atom (tungsten is a heavy refractory metal frequently used for X-ray tube targets), the pinhead nucleus would weigh about 370 tons.

The rest of the atom, the great bulk of the space in our room, would be occupied only by the atomic electrons. For each tungsten atom there would be 74 of these electrons, which we might picture as darting rapidly about in the room with terrific velocity like a cloud of extremely agile gnats or other insects, so that all parts of the room would be continuously explored by them with great rapidity.

We must be careful not to push the analogy too far. Although the electrons, like the gnats, have little mass compared to the nucleus, unlike the gnats they are bound to the nucleus by, and repel each other with, gigantic forces. They also have other far less familiar wavelike properties that profoundly affect and condition the behavior of a given electron in terms of the behaviors of neighboring electrons. Thus, although most of the mass (370 tons) of our tungsten atom is in the little pinhead nucleus and the rest of the room (atom) is in a sense almost empty space, that space is highly forbidden ground for encroachment by the similar parts of any neighboring tungsten atoms.

¹A convenient unit of energy in physics is the electron volt. It is the energy acquired by an electron when the electron is accelerated through a potential difference of one volt and is equivalent to 1.6021×10^{-12} erg or 1.6021×10^{-19} watt-second.

One of the important duties that the electrons accomplish in their ceaseless flying about is, through their force fields, to ensure the rigidity of the three-dimensional atomic latticework that constitutes the structure of any solid (in our present case, tungsten). Fast electrons accelerated by X-ray tube voltages of tens or hundreds of kilovolts can, however, be driven at high speed through such a structure, although the energy transferred from the fast electron to the atomic electrons is very high (of the order of one to ten million electron volts per centimeter of its path).

We may picture one of these fast electrons from the X-ray tube cathode being driven into the heart of the tungsten target by the high voltage with which it has been impelled against it and weaving its way through the cloud of electronic gnats. At the center of each atom (our "room") through which this dashing visitor passes is the tiny pinhead 370-ton nucleus, which (in the case of tungsten) has a positive charge some 74 times as great as an electron and, of course, of opposite sign. If the fast electron passes this positively charged nucleus at some distance from it, there will be enough negatively charged electrons between the two to shield the fast electron considerably from the strong attraction of the nucleus; but occasionally, by chance, the fast electron may pass close enough to the nucleus to be strongly deflected by its attraction. When such an event occurs, the impulsive kick or acceleration that the fast electron experiences will cause some (perhaps a substantial fraction) of its kinetic energy to be converted into a quantum of electromagnetic radiation in accord with the principle that any charged body that experiences an acceleration can be expected to emit electromagnetic radiation.

In the case of a head-on collision between a fast electron from the X-ray tube cathode and a tungsten nucleus, the maximum possible energy available to be converted into a quantum (photon) of radiation is the entire kinetic energy of the bombarding electron, an energy which, if expressed in electron volts, is essentially equal numerically to the voltage applied to the terminals of the X-ray tube. The photons of radiation constituting that part of the continuous spectrum of X-rays that appears at its quantum limit (the highest frequency, or shortest wavelength, of the spectrum) are formed by such head-on collisions with nuclei at the very surface of the target. In these collisions the entire kinetic energy of the fast electron, before it has had an opportunity to be dissipated in any other way, is converted completely in a single elementary process into a quantum of X-radiation. Between this most favorable (but rare) case of 100-percent conversion and the cases of more distant interactions between electrons and nuclei in which only a small fraction of the kinetic energy is so converted, all gradations are possible. This explains the presence of an entire continuum of wavelengths, frequencies, or quantum energies in the continuous X-ray spectrum.

The line spectrum, which is also emitted by X-ray tubes, is found to consist of several series of distinct, well-defined lines whose wavelengths, frequencies, or quantum energies depend on the particular atoms of which the target is made. These lines, in fact, represent the characteristic response made by the electron "gnats" surrounding the atoms of the target to the disturbance created among them by the passage of the bombarding cathode-ray electrons.

Laue Spots.—An advance of tremendous importance was made in 1912 when at the suggestion of Professor Max von Laue in Munich the two physicists W. Friedrich and P. Knipping tried directing a fine pencil of X-rays at a crystal of zinc blende (zinc sulfide). They found that the X-rays were "reflected" in a large number of well-defined directions by the crystal so as to form a regular pattern of spots (now known as Laue spots) on a photographic emulsion placed in the vicinity. It rapidly became evident that a similar phenomenon could be expected for any crystal, the pattern of spots being closely related to the atomic latticework structure of the crystal. The analytically correct but somewhat intricate explanation of these spots given by von Laue became much easier to understand intuitively after the work of William Henry and William Lawrence Bragg (father and son) in England the following year.

To understand this we need to explain briefly what has been revealed, chiefly by studies with X-rays, about the structure of crystals. It is found that the atoms in a crystal arrange themselves in three-dimensional latticework patterns of which one of the simplest, the only one we shall describe, is that of rock salt (consisting of sodium and chlorine atoms in equal numbers). Picture a plane surface dotted with sodium and chlorine atoms in an alternate square array, such as one would obtain if the center of each black square of a checkerboard were occupied by a sodium atom and the center of each white square by a chlorine atom. Next, picture a three-dimensional array consisting of such checkerboards piled upon one another in layers so adjusted that each sodium atom has a chlorine atom just above and below it and each chlorine a sodium just above and below it. In the case of sodium chloride the vertical separation between adjacent layers is the same as the horizontal separation between adjacent atoms in each square array. (In the actual crystal the atoms support each other in this rigid array through the force fields set up by their respective electronic structures; there is, of course, no question of tangible surfaces or checkerboards other than as a help to the imagination.)

Anyone who has looked from a railway train at a grape vineyard or an orchard of fruit trees laid out in regular square array will recall how the vines or trees not only align themselves in two mutually rectangular directions but also form straight rows in a great number of other directions as well. With a little imagination it will be easy to see that, in the three-dimensional atomic crystal lattices, there will in a similar way be a great number of differently directed plane surfaces that can be passed through the latticework in uniformly and densely studded patterns of atoms; and that, for every plane so tilted, there will in fact be an infinite number of other planes parallel to the one in question for which the same will be true. Each such set of parallel planes will constitute a layered array in which all adjacent pairs of planes have the same common interplanar spacing, although the spacing may be different for differently tilted arrays.

In Laue, Friedrich, and Knipping's experiment, each of these differently tilted arrays of planes accounted for each of the differently directed Laue-spot reflections of the primary beam. It is important, however, to understand that not any X-ray wavelength would be so reflected if it fell at an arbitrary angle upon a set of planes of

arbitrary spacing. The reflection is strong only when a certain relation, known as the Bragg condition, holds between the wavelength, λ , the angle of glancing incidence on the planes, θ , and the interplanar spacing, d . The relation is $n\lambda = 2d \sin \theta$, where n is a small whole number called the "order" of the reflection.

This Bragg condition is the analytical statement of the requirement that the X-ray wavelets emitted from a specified distant source point, after reflection by the planes (as though each were a mirror), must recombine at another distant observation point in exact phase coincidence. This occurs because the path traversed by an X-ray wavelet reflected by any one plane differs from that of a wavelet reflected by a neighboring plane by exactly a whole number of X-ray wavelengths. An X-ray of any wavelength λ , incident on a specified array of planes of spacing d at a specified angle θ for which the above Bragg condition is not fulfilled will pass on into (and perhaps through) the crystal until it has been absorbed, but it will not be appreciably reflected. What we have described, therefore, is frequently referred to as "selective reflection." It is easy to see how this principle can be used to analyze the radiation from an X-ray tube into its component wavelengths by studying the X-ray intensities selectively reflected from systems of crystal planes at different reflection angles.

Moseley's Atomic Numbers.—The next important step followed rapidly when in 1914 Henry Gwyn-Jeffreys Moseley, in two classic papers applying the principle of selective crystal reflection, presented a systematic study of the characteristic line spectra emitted by targets of various metals when they were subjected to cathode-ray bombardment. Moseley, who began these experiments in 1913, used an X-ray tube of special construction that permitted rapid and convenient substitution of several different target materials. He found that, unlike optical spectra, the characteristic X-ray spectra of atoms are relatively simple, consisting, for a given target element, of widely spaced groups of but a few lines. The groups were recognizable in all the elements examined by Moseley (some 17 elements in his first work). The simple pattern of lines was very much the same in each spectral group over this wide range of elements, save for the actual wavelength position in the spectrum at which a given line occurred; and it was of extreme significance that as Moseley passed from element to element in the periodic table of increasing atomic weights, the wavelength of a given line in the pattern, as observed successively in the spectrum of each element, varied in a regular and quite uniform way with only a few exceptions when plotted as a function of the ordinal number of the element in the series.

Furthermore, Moseley found that, even in the few exceptional cases, a completely uniform behavior of line wavelength as a function of ordinal number could be obtained by exchanging the order of a few adjacent pairs of elements from the original order of increasing atomic weight. Moseley showed that if ordinal numbers Z (subsequently called the *atomic numbers*) are assigned to the elements in a certain manner, namely, H-1, He-2, Li-3, Be-4, B-5, C-6, N-7, O-8, F-9, Ne-10, Na-11, Mg-12, Al-13, Si-14, P-15, S-16, Cl-17, Ar-18, K-19, Ca-20, and so on to Zn-30, then the square root of the frequency of a given X-ray line from any element is

a linear function of the atomic number (nearly proportional to it, in fact). Although Moseley's assignment of atomic numbers required in a few cases reversal of the generally prevalent order of increasing atomic weight, his numbering system turned out to be actually of much more fundamental significance than the system based on weight; it represents the number of positive unit charges possessed by the nucleus of each atom and therefore is an index of the number of electrons that the nucleus can bind to itself in its outer cloak (see PERIODIC LAW).

Only the year before, in 1913, Niels Bohr had proposed a quantitative model of the hydrogen atom based in part on a general earlier proposal of Lord Ernest Rutherford, who conceived the atom (correctly) as a heavy positively charged nucleus surrounded by a swarm of electrons equal in number and in charge (but of opposite sign; that is, negative) to the nuclear charge. It seemed a safe guess at the time that the swarm of electrons must be in rapid motion because of a mathematical theorem due to Samuel Earnshaw that gave convincing proof that no system of point charges could ever be in static equilibrium under the action of the fields of the charges themselves. On the other hand, according to the electromagnetic theory of radiation propounded by James Clerk Maxwell, any such system of moving charges must radiate electromagnetic waves and hence must lose energy. As a result, the cloud of electrons would be expected to fall inward closer and closer to the nucleus, and it became difficult to see what would place the final limitation upon this catastrophic shrinkage unless some new principle of stability were injected into the picture.

Bohr conceived the electrons as executing orbits about the central nucleus, but added the revolutionary new concept that out of the infinitude of classically possible orbits and energies that such electrons could possess, only certain orbits possessing well-defined energies had the special property of not dissipating their energy into radiation. According to Bohr's proposal, spectral lines were emitted when and only when the electronic orbits executed a transition from one of these nonradiating states to another such state of lower energy, the frequency emitted being given by the energy set free in the transition divided by Planck's quantum of action, h . Bohr's theory, which has turned out to be one of the major steps of progress in the quantum theory originated by Max Planck, predicted a formula for the wavelengths of the lines to be expected from atoms of atomic number Z . The formula successfully explained the wavelengths of the lines observed in the spectrum of hydrogen, the simplest of all atoms. Bohr's theory had indeed been constructed precisely for the purpose of explaining these hydrogen lines.

It was a matter of great significance, however, when Moseley showed that Bohr's formula also succeeded in predicting with quantitative success the wavelengths of X-ray lines in the entire series from aluminum ($Z = 13$) to zinc ($Z = 30$), which he had just measured. This was the first strong evidence of any family relationship between the atoms of chemistry, and it was an important opening wedge in the conquest of our understanding of the atomic world.

Compton Effect.—The next extremely important fundamental contribution in the field of X-ray research was made by Arthur Holly Compton in 1923. Physicists had already recognized

no distinct processes whereby matter when illuminated by electromagnetic radiation (light or γ -rays) itself reemits radiation. The first of these two processes, sometimes called fluorescence, was thought of as a two-step process. The atom first absorbed the luminous energy in such a manner as to modify the energy states of its electrons so that the electrons would assume new dynamic configurations. One or more electrons might indeed even be completely ejected from the atom, leaving therein an unfilled energy state. The atom was then said to be in an "excited state." Subsequently, then, the atom returned to its original lowest energy state (called the "ground state") and in so doing divested itself of its energy of excitation by emitting luminous frequencies (or wavelengths) *characteristic of the particular atomic species to which it belonged*. Such a process accounted for the spectral "lines" observed in both the visible and in the X-ray spectrum, by which the various atoms of chemistry could be identified. Such radiations were frequently referred to, therefore, as characteristic fluorescent radiations. In the emission process the electrons in the atom were thought of as vibrating freely at their own natural characteristic frequencies, frequencies determined by the particular structural characteristics of the atomic species in question. In some cases the time delay between absorption of the radiant energy and subsequent emission of the characteristic fluorescent radiation was sufficiently long to be easily perceptible. When such was the case the process was called phosphorescence. Both phosphorescence and fluorescence are particular cases of a more general phenomenon called luminescence (q.v.).

The second of the two types of radiation-matter interaction was known as scattering. In this process the wavelength (or frequency) of the reemitted light had, up until the year 1920, always been thought to be identical with the wavelength (or frequency) of the incident light. The process was ascribed to forced vibrations of the atomic electrons induced by the oscillating electromagnetic field of the incident beam of light waves. These vibrating electrons themselves then gave off light waves of the same frequency (or wavelength) as the waves of the incident light beam. The luminous energy in the original light beam would obviously be diverted into new directions by the process just described; hence the use of the term "scattering" (of light or X-rays) to describe the process.

Both of these two quite distinct processes, fluorescence and scattering, had been observed to occur when X-rays encountered matter. The two processes could indeed occur simultaneously, and the relative probabilities that atoms of a given species would (1) absorb and then reemit characteristic fluorescent radiation or (2) scatter the original wavelength had been carefully studied and found to depend according to very definite laws on the atomic number, Z , and on the wavelength of the original incident radiation. Joseph Alexander Gray in 1920, however, noticed that short-wavelength X-radiation, after being scattered from carbon and other atoms of low atomic number, was somewhat more absorbable than the primary radiation, but still of a "hardness" so clearly related to the primary radiation as to exclude its being a characteristic fluorescent radiation from the scatterer. Compton gave the following daring explanation of this effect. He supposed the bundles of radiation energy, $h\nu$, instead of

being associated with spreading waves, to be propagated through space from the source in the form of projectiles. When one of these projectiles (or photons), each with momentum $h\nu/c$, was scattered by a loosely bound electron in some low-atomic-number scattering material such as carbon, the electron would recoil under the impact, the more so the larger the angle of scattering and the higher the quantum energy (and hence the momentum) of the projectile. The kinetic energy thus given the electron at the expense of the photon explained the "softening" of the scattered radiation in a completely and quantitatively correct way.

Using characteristic line radiation from a molybdenum-target tube, Compton showed that in the spectrum of the scattered radiation there appeared lines each of which was shifted toward a longer wavelength than its corresponding line in the primary radiation by an amount in complete accord with his theoretical explanation. The recoil electrons were also detected and shown by Compton and A. W. Simon to have the requisite speeds and directions of recoil. Even more than this was ascertained, for Jesse W. M. DuMond and Harry A. Kirkpatrick succeeded in showing that the shifted line just referred to was notably broader than the unshifted line, and this was satisfactorily explained by them (with complete quantitative verification in all respects) to be due to the randomly directed velocities possessed initially by the atomic electrons that scattered the photons. The presumptively dynamic character of the electronic clouds in atoms was thus experimentally verified.

De Broglie's Wave Theory.—In the same year (1923) Louis Victor de Broglie made a very bold suggestion regarding electrons, namely, that besides their aspect as particles they might also possess undulatory properties. He came to the conclusion that a stationary electron of mass m_0 , which Albert Einstein had predicted must possess a "rest energy" m_0c^2 , must have associated with it a frequency m_0c^2/h . He concluded further that a moving electron would behave in many respects like a train or small bundle of plane waves of wavelength h/p , where p was its kinetic momentum. Both Einstein's and de Broglie's superlative insights were regarded as fantasies at first. The energy m_0c^2 has since then become only too familiar as a commonplace closely associated with its military application in atomic bombs. Four years later de Broglie's electron waves were actually verified, with quantitative corroboration of his formula, by Clinton Joseph Davisson and Lester Halbert Germer, who showed that electrons were selectively reflected from a single crystal of nickel in just the same manner as explained above for the reflection of X-rays.

Erwin Schrödinger had almost immediately seized upon de Broglie's idea of the electron as a *matter wave*, and with rare skill and insight had refined it in the form of a differential equation that in a sense fused the wavelike properties of the electron with its character as a mass particle obeying the laws of mechanics. From this point of view the stationary states of the electrons in atoms, which Bohr had been obliged to postulate ad hoc, appeared as permanent modes of vibration (standing waves) of a complex quantity, Ψ , called the probability amplitude, with distinct improvements and clarifications of several puzzling difficulties that had afflicted the simpler Bohr theory.

In 1927 Schrödinger proposed an alternate theory of the Compton effect based entirely on the wave picture of both electrons and photons, in which the initial and final states of the initially free recoiling electron interfere with each other to form a space grating of standing matter waves that reflects undulatory X-radiation like the atomic layers in a crystal. The change in wavelength in this picture of the modified scattering process is ascribed to a Doppler effect (see DOPPLER'S PRINCIPLE) caused by the velocity of recoil of the reflecting space grating. No basis for preferring either Compton's or Schrödinger's viewpoint can be found, and indeed we have here one of the striking examples of *wave-particle duality*, which, thanks to the work of Schrödinger, Werner Heisenberg, Bohr, and others, is now recognized to be a common property of all forms of energy, be it matter or radiation.

The discovery of the Compton effect with its two complementary interpretations, together with the quantum theory of optical and X-ray spectra and the wavelike properties of electrons, led directly to Heisenberg's famous principle of indeterminateness and to Bohr's principles of complementarity and renunciation, discussions of which are beyond the scope of this article. These important ideas form the groundwork of quantum theory, upon which repose most of the advances made in theoretical atomic and nuclear physics during the first half of the 20th century by Bohr, Schrödinger, Heisenberg, Arnold Sommerfeld, Wolfgang Pauli, Paul Adrien Maurice Dirac, Enrico Fermi, and many others. The insight thus gained into the weird subatomic world has obliged us to revise completely our intuitive notions of space, time, and causality, and has brought about one of the most drastic and deep-rooted revolutions in human thinking that has occurred in the entire history of the race. See also ATOM; ELECTRON THEORY; QUANTUM THEORY.

Professor of Physics, California Institute of Technology.

Continuous and Line Spectra.—As explained previously, the spectrum produced by an X-ray tube consists of a continuous broad band of wavelengths having a distribution that depends primarily on the voltage applied to the tube (see Fig. 1), and a few sharp, intense characteristic lines whose wavelengths depend on the target element (see Fig. 2). The optical emission spectrum has thousands of lines, whereas the X-ray line spectrum has only a few lines (see Plate 1). The wavelengths of the X-ray lines increase according to simple rules, thereby simplifying their identification.

The continuous spectrum for a given accelerating voltage V of the electrons begins abruptly at a minimum wavelength λ_{min} , rises to a broad peak, and falls off gradually with increasing wavelength. The limiting wavelength in angstroms (Å) is related to the voltage in kilovolts (kv) by the equation

$$V = 12.398/\lambda_{min}. \quad (1)$$

As the voltage is increased, the energy carried by each electron emitted by the filament is increased. This causes the intensity to rise and the spectrum to shift to shorter wavelengths.

The investigations of Charles Glover Barkla and his coworkers, beginning about 1913, showed that the elements possess two types of character-

W. Parrish, "Philips Technical Review," 1956

Fig. 1. Continuous spectrum of tungsten-target X-ray tube (relative intensity I_{rel} v. wavelength λ) obtained with various voltages (peak values) and same X-ray tube current. Measured with silicon crystal analyzer and scintillation counter.

istic (line) radiations, which differ greatly in their penetrating power. Barkla called these K- and L-radiations (the M- and N-radiations or series were discovered later) and, using a number of elements, measured their absorption in aluminum. It is now known that when the voltage is increased to give the electrons from the cathode sufficient energy to remove an electron from an orbit in, say, the M-shell of the target atom, all the M-lines of the characteristic target spectrum will be emitted in addition to the continuous spectrum. On further increasing the voltage the intensities of the M-lines increase, and at a certain higher voltage groups of lines of the L-series will appear. At a still

Fig. 2. Upper dark curve: Spectrum from copper-target X-ray tube operated at 40 kilovolts peak (full-wave rectification), 0.012-mm thick mica and 0.12-mm thick beryllium X-ray tube window, measured on diffractometer with silicon crystal analyzer and scintillation counter. Dashed curve: 0.014-mm thick nickel filter inserted in X-ray path nearly eliminates $\text{CuK}\beta$ line and causes a 45 percent reduction in $\text{CuK}\alpha$. Dotted curve: Obtained with filter and pulse-height analyzer set to transmit 90 percent of $\text{CuK}\alpha$ (transmitted by filter); most of short-wavelength continuum is eliminated. The $\text{WL}\alpha$, β , and γ lines arise from small amount of tungsten impurity on copper target. The L, Mo, Cu, and NiK-absorption edges originate in the scintillation crystal, slits, target, and filter, respectively.

W. Parrish, "Instruments and Measurements," Academic Press, N.Y., 1960

higher voltage the K-series will appear. For example, the minimum voltages V_0 (in kv) required to produce the M-, L-, and K-series of platinum, and the wavelengths, of the most intense line in each series (called alpha one, α_1) are as follows:

Line	V_0	λ
PtMa ₁	2.8	6.023
PtLa ₁	13.9	1.310
PtKa ₁	78.4	0.185

The absorption coefficient (which is a measure of the penetrating power of the radiation) is shown as a function of wavelength in Fig. 3. (This property is discussed in section 2. X-Ray Spectrochemical Analysis—X-Ray Absorptiometry.)

W. Parrish, "Philips Technical Review," 1956

Fig. 3. Mass absorption coefficient (μ/p) of platinum shown as a function of wavelength in the regions of the K-, L-, and M-absorption edges. Some characteristic emission lines of the K-, L-, and M-series are indicated by arrows.

The voltages required to produce the characteristic lines of each series increase with the atomic number of the element. Thus, to begin to produce the K-series of aluminum only 1.6 kv must be applied to the X-ray tube, while production of the uranium K-series requires a minimum voltage of 117 kv. The intensity, I , increases rapidly as the applied voltage, V , is increased above V_0 according to the relation

$$I = k(V - V_0)^n, \quad (2)$$

where k is a constant and n is 1.5 to 2. If a constant voltage is applied to the X-ray tube, the intensities remain constant (assuming the tube current is also held constant), but if the voltage is pulsating, that is, half- or full-wave rectified, the characteristic X-rays are produced only during those portions of the time cycle when V exceeds V_0 . Consequently, the need to use constant potential to achieve high intensities increases with V_0 (or with decreasing wavelength). Similarly, the continuous X-ray spectrum shifts back and forth during each half cycle and attains its extreme short-wavelength position only during the peak of the operating voltage, whereas with constant potential all wavelengths and intensities corresponding to the voltage are continually produced. Increasing the current of the X-ray tube increases the intensities of all the wavelengths in a linear manner and does not change the wavelengths.

In 1913, Moseley measured the characteristic

X-ray line spectra of a number of elements and found that the square root of the frequency of the various lines and the atomic number of the emitting element exhibit a nearly linear relationship, as shown in Fig. 4. This fundamental law, which is the basis of X-ray spectroscopy and which, as explained earlier, also played an important role in the early conception of atomic structure and the acceptance of Bohr's model of the atom, shows that each element has a characteristic X-ray line spectrum and that the wavelengths vary in a regular predictable fashion from one element to another. The wavelengths decrease as the atomic numbers of the elements increase.

W. Parrish, "Philips Technical Review," 1956

Fig. 4. Wavelengths of four characteristic X-ray spectral lines of elements plotted against atomic number, Z . Moseley's law specifies a linear relationship between $1/\sqrt{\lambda}$ and Z .

The K-lines consist of a doublet, $K\alpha_1$ and $K\alpha_2$, having nearly the same wavelengths and a $K\beta$ line, which consists of three lines, usually unresolved, of shorter wavelengths. In the case of a copper target the wavelengths in Å and relative intensities are:

Line	Wavelength	Relative intensity
CuK β	1.39217	25
CuK α_1	1.54051	100
CuK α_2	1.54433	80

The wavelengths in Å of some of the characteristic lines of six elements follow:

Element	Atomic number	K β_1	K α_1	L β_1	L α_1
Al	13	7.981	8.338		
Cr	24	2.085	2.290	21.32	21.71
Zn	30	1.296	1.435	12.01	12.28
Zr	40	0.701	0.786	5.84	6.07
Nd	60	0.294	0.332	2.166	2.370
U	92	0.111	0.126	0.720	0.911

Monochromatic X-Ray Beams.—The simplest method of obtaining monochromatic X-rays is to use a filter whose K-absorption edge lies between the $K\alpha$ and $K\beta$ lines; for example, the use of a nickel foil 0.014 mm thick inserted in the X-ray

beam from a copper target reduces the $K\beta$ line to 1 percent of its original intensity and also causes a reduction in the continuous spectrum, but reduces the $K\alpha$ -line intensity by only 45 percent (see dashed curve in Fig. 2). The K-absorption edge lies at a slightly shorter wavelength than the $K\beta$ line, and is the wavelength at which there is a large change in X-ray absorption. In the immediate vicinity of this wavelength, the X-ray absorption is much higher at the shorter than at the longer wavelengths. The wavelength at which the edge occurs increases with decreasing atomic number in the same manner as the characteristic lines. There are also L- and M-absorption edges, as shown in Fig. 3.

W. Parrish, "Philips Technical Review," 1956

Fig. 5. Three common types of counter tube used for quantitative measurement of soft (low-energy) X-rays. X indicates incident X-ray beam, W is a thin, low-absorbing window, A the wire anode, C the cylindrical metal cathode, SC a scintillation crystal, and PT a photo-multiplier tube. Geiger counter is about 10 cm long and filled with argon to about 55 cm (Hg) pressure. Proportional counter is about 2 cm in diameter and filled with xenon to 30 cm (Hg) pressure. X-ray beam is absorbed in the gas or in scintillation crystal.

Another method of monochromatization is to use a proportional or scintillation counter (Fig. 5) together with a single-channel pulse-height analyzer. The average amplitudes of the pulses in these detectors are proportional to the energies of the X-ray quanta producing them. By setting the lower (base) level of the analyzer to reject all pulses below a selected amplitude, and the upper (window) level to reject all pulses above the selected amplitude, the system can be made to transmit only those pulses whose amplitudes lie within a selected range of X-ray energies. However, as a consequence of statistical processes involved in the production of these pulses, not all pulses produced by a single X-ray energy have exactly the same amplitude. There is instead a small spread of pulse amplitudes for each X-ray wavelength. Although perfect monochromatization thus is not possible by this electronic method, the degree of monochromatization achieved when the beta filter and pulse-amplitude discrimination

are used together (see dotted curve in Fig. 2) is sufficient for most applications. The pulse-height analyzer causes only about a 10 percent reduction of the $\text{CuK}\alpha$ intensity transmitted by the nickel filter, but the continuous radiation is almost entirely eliminated.

Fig. 6. Conditions for X-ray diffraction. X-rays of wavelength λ_1 are diffracted by crystal C only at angle θ . Central ray of wavelength λ_1 is not diffracted because angle of incidence is different from θ_1 . Rays of a different wavelength λ_2 are diffracted at a different angle θ_2 .

When X-rays are diffracted (see section J. *Physics of X-Rays—Bragg's Law*) from a nearly perfect single crystal, only a very narrow band of wavelengths appears in a given direction. This is shown schematically in Fig. 6, in which parallel

Johannson crystal monochromator. A parallel beam of monochromatic X-rays originating at X is diffracted by monochromator C so that all rays converge at R. Rays must strike crystal atomic planes bent to radius $2r$ at angle θ . Crystal surface is ground to radius r to match focusing circle F.

rays of one wavelength λ_1 are diffracted at the same angle θ_1 . Inclined rays of the same wavelength do not make the correct angle and cannot be diffracted by the crystal. Rays of another wavelength λ_2 will be diffracted at another angle

6. The X-ray reflection coefficients of the best crystals are less than about 10 percent and hence there is a large loss of intensity. T. Johansson devised a monochromator that utilizes a crystal surface ground to a radius r and bent to a radius $2r$, as shown in Fig. 7. If the X-ray source is very small the divergent beam of monochromatic X-rays will be focused perfectly at R , thereby permitting a large angular aperture and hence a corresponding increase of intensity over the flat-crystal monochromator.

Monochromatic X-rays may also be obtained by X-ray fluorescence, as described later, and from radioactive sources, as for example Fe^{55} decaying by K-capture to Mn^{55} and generating MnK X-rays in the process. The intensities in both these methods are much lower than those obtained by direct electron excitation in X-ray tubes.

Bragg's Law.—The atoms in crystalline substances are arranged in a symmetrical, repeating, three-dimensional pattern, and the distances between planes of atoms are of the magnitude of X-ray wavelengths. Hence, crystals act as three-dimensional gratings for X-rays in a manner analogous to the diffraction of ultraviolet or visible light by a ruled one-dimensional grating (see DIFFRACTION OF LIGHT). Under appropriate conditions the electrons associated with each atom will scatter an incident X-ray beam in a coherent manner, so that in certain specific directions the scattering from millions of atoms will be in phase at the same time.

It was shortly after von Laue's 1912 discovery of X-ray diffraction by crystals that this complex phenomenon was formulated in a simple geometrical relation by the Braggs. They showed that X-ray diffraction could be visualized as a reflection from a large number of parallel atomic planes according to the equation

$$n\lambda = 2d \sin \theta, \quad (3)$$

where n is a small integer giving the order of reflection analogous to the ruled grating, λ the wavelength of incident X-rays, d the distance between planes of atoms, and θ the angle between the incident X-ray beam and the atomic planes

Fig. 8. Conditions for reflection of X-rays from successive lattice planes, as required by Bragg's law. θ , glancing angle; 2θ , reflection angle; λ , wavelength; d , interplanar spacing.

(see Fig. 8). There is only one θ angle at which the reflected rays are in phase for a given value of d and λ . At other angular positions of the crystal there is destructive interference and no reflections occur, as was indicated in Fig. 6. Thus the conditions for obtaining an X-ray reflection are very

restrictive, a reflection occurring only when X-rays of the same wavelength strike a crystal at the same glancing angle θ to a set of equally spaced atomic planes and when the path difference of the rays from adjacent planes is an integral number of wavelengths. (This reflection phenomenon should not be confused with the nearly total reflection of X-rays that occurs at very small glancing angles from highly polished surfaces.)

Consider, for example, the case of reflection of $\text{CuK}\alpha$ X-rays, $\lambda = 1.54 \text{ \AA}$, from one set of atomic planes of a flat, single-crystal plate of quartz in which $d = 3.34 \text{ \AA}$. When this set of planes makes an angle of 13.3° (θ) with the incident X-rays, a reflection occurs at twice this angle, 26.6° (2θ), with respect to the incident beam. A second-order reflection, $n = 2$, occurs at $2\theta = 54.9^\circ$, but there are no reflections between these angles. If $\text{CrK}\alpha$ X-rays ($\lambda = 2.29 \text{ \AA}$) had been used, the first-order reflection would have occurred at 40.0° (2θ) and the second-order reflection at 86.5° (2θ). The relative intensities of the reflections depend upon the atomic scattering factors and the atomic structure of the crystal (see CRYSTALLOGRAPHY—4. Crystal Structure).

A simple application of Bragg's law proved of great value during World War II in the manufacture of millions of quartz oscillator plates for use in frequency control of military communications. These crystals had been made in small quantities, but the sudden unprecedented requirements made it necessary to develop mass-production methods. The desired crystals required precision-cut angles with respect to the crystallographic axes. After an approximate visual or optical orientation of the raw quartz crystal, a test slice was cut with a diamond-impregnated saw, its precise orientation measured with X-rays, and the sawing angle corrected accordingly. Special X-ray machines with counter-tube detectors were developed that permitted unskilled personnel to make accurate measurements of the reflection angle in about 15 seconds. This technique was the first use of X-rays as an integral part of a manufacturing process.

2. X-Ray Spectrochemical Analysis

It was explained above that each element can be induced to emit the X-ray line spectrum characteristic of that element. Two methods have been used for emission analysis: the specimen, consisting of one or more elements, may be bombarded with electrons, as in the case of an X-ray tube, or the specimen may be irradiated by X-rays of higher energies (that is, shorter wavelengths) than the absorption edges of the elements causing X-ray fluorescence. See this section—X-Ray Absorptiometry.

X-Ray Spectrographs.—The radiation emitted by the sample is analyzed with an X-ray spectrograph, which consists of the X-ray source, a system of slits, a single crystal, a counter-tube detector and its electronic circuits, and a goniometer, an instrument that indicates the angles precisely and automatically scans the spectrum. The elements are identified (qualitative analysis) from the angles at which the crystal reflects each wavelength in accordance with Bragg's law, equation (3). The concentrations are determined (quantitative analysis) from the relative intensities by use of suitable calibration curves. Two major types of spectrograph geometry have been employed: nonfocusing (flat crystal) and focusing (curved crystal). A photograph of a complete X-

ray fluorescence spectrograph is shown in Plate 1.

A schematic diagram of the arrangement used in a modern nonfocusing X-ray spectrograph is shown in Fig. 9. Radiation is emitted either directly from the X-ray tube or from the fluorescent specimen. X-rays traveling in a certain direction pass through the parallel-slit assembly (Soller slits), whose thin, equally spaced, highly absorbing metal foils collimate the X-rays and limit the breadth of the recorded reflection. The single-crystal plate, oriented to reflect from only a single

Fig. 9. Schematic drawing of nonfocusing X-ray spectrograph. X, X-ray tube; E, slits to reduce scattered radiation; S, large flat specimen; P, parallel Soller slits (one or two sets may be used); C, flat crystal; D, counter tube; θ , Bragg angle; 2θ , reflection angle; G, goniometer scale.

set of planes with a known d -spacing, reflects one wavelength at a given angle in accordance with Bragg's law. By slowly rotating the crystal at one half the angular speed of the detector, the various wavelengths from the parallel beam of X-rays are reflected one by one as the crystal makes the proper θ -angle for each wavelength. The intensity at each wavelength is then measured with a high-sensitivity scintillation counter or similar detector and automatically recorded.

W. Parrish, "Philips Technical Review," 1956

Fig. 10. Schematic drawing of focusing X-ray spectrograph. Letters same as for Fig. 9 except F, focusing circle; S, small specimen; C, curved crystal; R, receiving slit. Soller slits, whose foils are parallel to plane of drawing, are not shown.

The focusing X-ray spectrograph, one type of which is shown in Fig. 10, is required for very small specimens. The specimen surface, the surface of the curved crystal (prepared as shown in Fig. 7), and the receiving slit are situated on the

focusing circle. To measure different wavelengths the crystal is moved around the focusing circle at one half the angular speed of the receiving slit and detector, as shown by the dotted lines. At the same time the detector is swiveled to always point at the center of the crystal.

Both the angle at which the various wavelengths are reflected and the angular separation (dispersion) of the wavelengths are dependent upon the d -spacing of the reflecting atomic planes of the crystal analyzer, as shown in Fig. 11. (The

Fig. 11. Effect of crystal-analyzer lattice spacing d on positions of $K\alpha$ lines of several elements (schematic)

numbers hkl used in Fig. 11 are the Miller indices of the reflecting planes (see section 3. X-Ray Powder Diffraction—Determination of Miller Indices). Three common crystals are depicted as analyzing the $K\alpha$ reflections of three sets of adjacent pairs of elements. When the value of d decreases the reflections occur at larger angles and have a greater separation, as can be seen by differentiating Bragg's equation:

$$\frac{\Delta\theta}{\Delta\lambda} = \frac{n}{2d \cos \theta} \quad (4)$$

It is thus easy to increase the dispersion simply by using a crystal with a smaller d . The crystal analyzer cannot reflect a wavelength larger than $2d$, and in practice the upper limit of wavelengths that can be measured is further restricted because the goniometer cannot scan beyond about 150° (2θ) due to mechanical restrictions.

The spectrograph may be eliminated in certain relatively simple cases involving routine analyses of a series of samples containing a small number of known elements within a fixed range of composition. The radiation to be analyzed enters directly into a proportional or scintillation counter, and the analysis is based on the fact that each wavelength produces a different known average pulse amplitude. Separate channels of a multi-channel pulse-height analyzer are used for each element in this nondispersive method. By eliminating the crystal, the intensity is greatly increased and all the elements may be determined simultaneously. However, the relatively poor energy (wavelength) resolution of the counter tubes causes overlapping pulse-amplitude distributions from nearby wavelengths and limits this method to the analysis of elements whose wavelengths are well separated from one another.

X-Ray Emission Spectroscopy.—The direct, or electron, excitation of X-ray spectra was the method first used by Moseley, Karl Manne Georg Siegbahn, and others to measure X-ray wavelengths. It was soon recognized that the method could be used for chemical analysis, and in fact

Moseley obtained the spectrum of a piece of brass that showed strong copper and somewhat weaker zinc lines, and this was the first X-ray chemical analysis. The element hafnium was discovered by Georg von Hevesy in 1922 from its X-ray spectrum. However, the method was not widely used because it obviously is limited to those specimens that can be made into the form of an X-ray tube target. The specimen must withstand the high-energy electron beam and the vacuum and it must not disintegrate from the heating in the X-ray tube. Steel and alloy samples have been analyzed in this manner. The sensitivity is high due to the high intensities.

In 1950, R. Castaing modified the method for microanalysis. He altered the electron-optics column of an electron microscope by adding a second electrostatic lens to obtain an electron beam about 1 micron (μ) in diameter. The specimen was mounted in the vacuum chamber on an accurately machined table that could be adjusted from the outside to bring the desired area of the specimen into the fine electron beam, the positioning being observed with an optical microscope. In this method the emitted X-rays are analyzed by a focusing X-ray spectrograph and counter tube. The X-ray tube current is about 1 microampere, which is much lower than in normal X-ray tubes, so that the problem of specimen heating is virtually eliminated. Nonmetallic specimens are usually first coated with a thin metallic layer to eliminate charging of the surface. By moving the specimen, point-by-point chemical analyses can be made. Although the instrumentation is quite complex, the method has found wide application in a variety of fields, particularly in metallurgical studies, and yields information on a microscale that cannot be obtained in any other way. It is claimed that for elements in the middle of the periodic table the ultimate detection limit is about 10^{-11} gram.

X-Ray Fluorescence Spectroscopy.—The fluorescence method is by far the more common method of emission analysis because the specimen preparation is much simpler, the apparatus is less complex, and the calibration is easier to perform. The lines of the fluorescence spectrum have the same characteristic line wavelengths as the electron-excited lines, and the continuous spectrum is absent. The fluorescent lines observed in an X-ray spectrograph are approximately $1/1000$ as intense as the direct-electron-excited lines, but with modern high power X-ray tubes and counter tubes having nearly 100 percent quantum counting efficiency the intensities are sufficiently high to allow their use for routine analysis, as was shown by Herbert Friedman in 1947. The electron beam is focused on a relatively large area of the target to allow the maximum power to be applied to the X-ray tube. The specimen must be placed very close to the window (on the outside of the X-ray tube) because the primary X-ray intensity diminishes as the square of the distance between the target and the specimen.

An element produces the strongest fluorescence when irradiated by primary X-rays of wavelengths slightly shorter than its absorption edge. Thus, the characteristic lines from a copper target, $\text{CuK}\alpha$ and $\text{CuK}\beta$, $\lambda = 1.54 \text{ \AA}$ and 1.39 \AA , produce strong secondary X-rays in cobalt, whose absorption edge is at 1.61 \AA , but no fluorescence in zinc, whose edge is at 1.28 \AA .

Instead of using only the characteristic lines of the X-ray target material, which would excite

strong fluorescence in only a few elements, the continuous "white" radiation is also used to cause a whole series of elements to fluoresce. A tungsten-target X-ray tube operating at 50 kv or more produces a large amount of continuous radiation as well as the tungsten L-spectrum, and is often used for this purpose.

Advantages Over Other Methods.—In many cases the X-ray method is more rapid than the optical method and the calibrations required for quantitative analysis are usually simpler. The X-ray method is superior for analyses involving amounts from 1 to 100 percent, wherein an accuracy of about 1 percent of the amount present can be achieved; the procedure requires about one minute of actual measurement (not including the time for calibration and specimen preparation). In general the optical method is more sensitive for trace-element analyses. Good results have been reported for the X-ray method for concentrations as small as 0.1 to 0.001 percent, but the accuracy is lower and the time required is longer. If the specimen is subjected to some prior physical or chemical process to enhance the concentrations of the minor elements, the lower limits of detectability may be greatly extended. Thus, analyses have been performed in the range of 1 part per million (ppm) or less on small samples prepared by concentration of a large sample. Microgram and smaller quantities of elements have been analyzed quantitatively in this manner. The X-ray method is as accurate as a quantitative chemical analysis, requires far less time, and is nondestructive.

Applications.—The fluorescence method has been applied to a great variety of problems, of which only a few are mentioned here. The analyses of rare-earth ores are very difficult to do by conventional chemical methods because the rare-earth elements have similar properties, but the X-ray method has been successful in the quantitative analyses of a large number of rare-earth elements present in such ores. Other examples include the determination of nickel, chromium, and other elements in high-temperature steels and the measurement of lead and bromine in gasoline, sulphur in oil, uranium in aqueous solutions, and the hemoglobin in blood.

The fluorescence method has been used for all elements from sodium to uranium. There are three major analytical regions determined by the wavelengths and instrumentation, as shown below.

Wavelengths (\AA)	V_0 (kv)	Atomic numbers and elements	Series
0.1-0.5	117-25	92 U-46 Pd	K
0.5-2	24-7	45 Rh-26 Fe 92 U-65 Tb	K L
2-12	6.5-0.8	25 Mn-11 Na 64 Gd-31 Ga 92 U-62 Sm	K L M

The first group of elements has the shortest wavelengths and hence a crystal with a small d (of the order of 1.5 \AA) is required. The elements of highest atomic number require the highest voltages to produce their K-lines, and since the apparatus is often limited to 50 or 60 kv the L-lines, which require much lower voltages, may be used. The second group covers the series of intermediate wavelengths most commonly used and requires the simplest instrumentation. The third group contains the long wavelengths beyond 2 \AA , which cause some experimental difficulties because they

are strongly absorbed in air. For example, about 90 percent of $\text{TiK}\alpha$, $\lambda = 2.75 \text{ \AA}$, is absorbed in a spectrograph having an air path 13 inches long, and either a helium-gas path or a vacuum chamber must be used. In addition, the fluorescent intensities of the longer wavelengths are much lower because the fluorescence yield decreases with increasing wavelength. (The primary X-rays from the X-ray tube are less efficient in producing long-wavelength fluorescence, and the absorption in the specimen is greatly increased.) The crystal must have a large d , of the order of 4.5 \AA . The $\text{NaK}\alpha$ line ($\lambda = 11.9 \text{ \AA}$) is about the longest wavelength that has been analyzed in routine measurements.

The specimens used for X-ray spectroscopy may be amorphous or crystalline powders, polished and etched metallographic specimens, or even liquids. There is a relationship between the fluorescent X-ray intensity as measured and the amount of element in the sample. The increase in intensity with concentration is seldom linear because of the absorption of the fluorescent X-rays by the specimen itself. Since the composition of the specimen may vary over wide ranges, the measured intensities show a marked dependence upon the absorption. Therefore, for accurate quantitative analysis, empirical calibration curves for each element of interest must be made with a small number of standard specimens of roughly the same composition.

Fig. 12. X-ray spectrograms (schematic) of copper and nickel. (Sodium chloride crystal.)

A fluorescence analysis of nickel and copper taken with a sodium chloride crystal analyzer is shown in Fig. 12. The upper two charts show the simple K-spectra of pure nickel and pure copper. The third chart shows the spectrum of a mixture of equal parts of nickel and copper. In this technique, a solid solution and a mixture give the same spectrum, unlike X-ray diffraction, described below. The $\text{CuK}\beta$ line is of relatively less intensity than in the case of pure copper because it is strongly absorbed by the nickel. The bottom chart, which shows the spectrum for a mixture of 10 percent nickel and 90 percent copper, reveals how the relative intensities are dependent upon the concentration of the elements in the specimen.

Use of Automation.—The X-ray fluorescence method is adaptable to a considerable degree of automation. The crystal and detector can be programmed to step automatically to a number of preselected Bragg-angle positions and the intensities recorded for each element in sequence. A series of samples can also be automatically in-

troduced in the spectrograph. Alternatively, by using a number of crystals and detectors, each set for a specific wavelength, all the elements in the sample may be determined simultaneously. After such instruments have been calibrated, the operation is simple and analyses are performed rapidly. Rapid analyses are required in industrial production control; for example, in following the increases in concentrations of certain elements during mineral-dressing processes.

X-Ray Absorptiometry.—Although X-rays are very penetrating, they suffer absorption as they pass through matter. The amount of absorption depends upon the X-ray wavelengths (energy) of the incident beam and upon the elemental composition and thickness of the sample. If I_0 and I are the intensities of the incident and transmitted beam, μ/ρ the mass absorption coefficient of the material (which is independent of the physical state of the material), ρ the density, and t the thickness, then

$$I = I_0 e^{-\frac{\mu}{\rho} \rho t} = I_0 e^{-\mu t} \quad (5)$$

If the specimen consists of a number of elements, whether in solid solution or as a mixture, and if the elements are evenly distributed throughout the specimen, the mass absorption coefficient can be related to the weight percentages w of the individual elements A and B in the specimen by the equation

$$\left(\frac{\mu}{\rho}\right)_{\text{spec.}} = \frac{w_A}{100} \left(\frac{\mu}{\rho}\right)_A + \frac{w_B}{100} \left(\frac{\mu}{\rho}\right)_B + \quad (6)$$

The absorption coefficients increase with wavelength of the incident beam and with atomic number of the absorbing element. The X-ray absorption is approximately proportional to the third power of the X-ray wavelength and to the fourth power of the atomic number of the absorbing element. There are sharp discontinuities in the absorption versus wavelength curve at the absorption edges of the element, as shown in Fig. 3. There are three absorption edges, L_I , L_{II} , and L_{III} , associated with the L-series of lines, and five edges associated with the M-lines, as shown.

If the incident beam is polychromatic, the absorption measurements will be difficult to interpret in terms of elemental composition. The use of monochromatic X-ray beams, although they are of much lower intensity than polychromatic beams, greatly simplifies the interpretation of the data. High sensitivity can be achieved by making several successive measurements using monochromatic beams having wavelengths on both sides of the absorption edge of the absorbing element. The sensitivity of the method depends on the change in absorption across the absorption edge. This change increases with decreasing atomic number, but since the low-atomic-number elements have their absorption edges at long wavelengths the technical difficulties increase. The method has been used to determine sulphur in hydrocarbons; uranium, thorium, and molybdenum in solutions; and for similar problems.

One of the important industrial applications in which the absorption of X-rays is used as a method of control is noncontact thickness gauging. An X-ray tube (or sometimes a radioactive

isotope) is mounted on one side of the continuously moving strip of homogeneous material that is to be gauged. The radiation that penetrates the material and reaches the detector on the other side is dependent on the absorption of the material and hence is inversely proportional to the thickness in the irradiated area. Automatic control may be arranged by having the detector signal correct the controls on the processes that determine the thickness, or reject pieces that are beyond the preselected tolerances. The method has been applied to the gauging of metal, rubber, and plastic thickness, the measurement of the density of cigarettes, and similar processes. (See also GAMMA RAY.)

Another application based on the absorption of fluorescent X-rays has been in the measurement of the thickness of thin tin plating on steel. The iron in the steel is irradiated to produce fluorescence, and the reduction of this fluorescent intensity as the X-rays pass through the tin plate provides a measure of the thickness of the plate.

3. X-Ray Powder Diffraction

It was shown previously that X-ray reflection from a single crystal occurs only under certain conditions satisfying Bragg's law. (For a discussion of single-crystal diffraction, see CRYSTALLOGRAPHY—4. *Crystal Structure*.) However, if the crystal is crushed to form a fine-grained powder, there will be many crystallites with the correct θ orientation for each of the d -spacings. The specimen also may be in the form of a solid polycrystalline aggregate or foil. This so-called powder method, the most widely used of all X-ray analytical techniques, was developed independently by Peter Joseph Wilhelm Debye and Paul Scherrer and by Albert Wallace Hull in 1917.

Scope of Method.—X-ray powder-diffraction studies are used in a great variety of applications. These include analysis and control of raw and finished products as well as research in the fields of ceramics, metallurgy, chemistry, mineralogy, biology, pharmacy, engineering, and electronics. Paint pigments, petroleum products, engine deposits, soils, metals and alloys, pharmaceuticals, catalysts, clays, boiler deposits, minerals, and soaps are but a few of the materials analyzed with X-rays. The powder method was used to determine the chemistry of the transuranic elements and their compounds. Many of these substances are highly radioactive with a short half-life, so that speed and safety were essential. These facts, and the small amounts of samples available, made chemical methods very difficult to apply. Several laboratories use X-rays for the routine analysis of quartz in industrial dusts. A procedure for the quantitative analysis of the minerals in bauxite exploration-samples has been developed in which the X-ray analysis gives results within 1 to 2 percent of chemical analysis in about 10 man-minutes, thus permitting an enormous saving of time. The X-ray analysis is made on the substance in its original solid form and is nondestructive with respect to the sample, whereas in chemical or optical spectrographic analysis the substance is dissolved, vaporized, or altered in some manner to determine the constituent elements.

An X-ray diffraction analysis of a mixture of the ore minerals chalcopyrite (CuFeS_2), bornite (Cu_5FeS_4), and pyrite (FeS_2) would

identify each of the three minerals, and their relative amounts could be determined. A chemical analysis would give the weight percent of copper, iron, and sulphur, but could not explain how these elements had been chemically combined; hence the minerals could not be identified. Such a limitation is also encountered in X-ray spectroscopy. To cite another example, the chemical analysis of a quartz sand used for making glass might show, in addition to silicon dioxide, impurities of a few percent of iron and titanium. In order to determine the best method of purification, it is necessary to know whether the impurities are present as a thin coating on the quartz grains or as separate admixed crystals of rutile, ilmenite, magnetite, or some other mineral. Microscopic examination combined with X-ray analysis will reveal how these impurities are present and their relative amounts, whereas chemical analysis would show only the bulk composition.

X-rays often afford the only practical means of following the course of a chemical reaction. For example, if an alloy of copper and nickel is desired, the required amounts of each element will be weighed, mixed, and heated. If the heat is insufficient for the elements to alloy, the X-ray pattern will be a mixture of the two patterns, as shown at the bottom of Fig. 18. Heating at a temperature sufficient to allow a complete reaction will give the X-ray pattern depicting a solid solution. No other method has proved as useful in following complicated reactions. For example, in the manufacture of ceramic magnetic materials, various substances such as the oxides of iron, zinc, and manganese are mixed together in their proper proportions and fired. A reaction occurs, forming a useful magnetic spinel phase having a totally different structure than the original individual oxides. If some of the oxides remain unreacted, the properties of the magnetic material will be altered. X-rays are used to study the course of the reactions and to work out the proper firing conditions. Chemical analyses are of little aid in such reaction studies because the end product has the same chemical composition as the original materials.

Powder Camera.—There are several methods of obtaining powder patterns. The simplest is to use a powder camera (see Fig. 13), which consists of a lighttight cylindrical chamber in which the film is mounted, holes for introducing a collimator tube, and a tube to conduct the undiffracted beam out of the camera without blackening the film. A small amount of powder is glued onto a thin (0.1-mm to 0.2-mm diameter), low-absorbing glass fiber that is mounted in the center of the camera and rotated continuously in the X-ray beam.

The probability of having crystallites in all possible orientations is large, provided the crystallites are of the order of 1 to 10 μ in size, and consequently all possible reflections from the various sets of atomic planes can occur simultaneously. Each crystallite may produce a reflection that will appear as a spot on the processed film. For any given value of d there will be a large number of crystallites in various orientations, each producing its own spot. The reflected rays will form the surface of a cone having its apex at the specimen and subtending the angle 4θ . Each set of atomic planes produces a separate concentric cone, and these

cones appear on the film as a series of arcs whose curvature depends on the particular reflection angle, as shown in Plate 2. The d -spacings are determined by measuring the linear distances on the film from the direct beam to each of the arc lines, converting these quantities into angular values (2θ), and substituting in the Bragg equation, the wavelength of the characteristic radiation being known.

W. Parrish, "Philips Technical Review," 1948

Fig. 13. Principle of powder camera. R , incident X-ray beam; P , cylindrical powder specimen; F , film; O , and O_1 , apertures.

The powder specimen scatters the continuous as well as the characteristic radiation, thereby adding to the background. André Guinier showed that when X-rays are first reflected from a curved crystal oriented for, say, the $K\alpha$ line, a thin flat specimen may be used in transmission to obtain the powder pattern, as shown in Fig. 14. The resulting powder pattern has a lower line intensity, but the background is greatly reduced compared with the previous camera described, so that it is easier to observe weak lines.

Fig. 14. Principle of Guinier focusing monochromator powder camera. Divergent X-ray beam originating at X is first reflected from focusing crystal C and then passes through flat specimen S . Focused diffraction lines are detected on film F .

X-Ray Diffractometer.—The X-ray diffractometer uses a highly sensitive soft X-ray detector in place of the film to record powder patterns automatically with greater resolution and precision than is possible by film methods. The system generally used was developed by William Parrish in 1947, and is shown schematically in Fig. 15. The specimen is prepared in the form of a flat or curved surface about 10 by 20 mm in area. The divergent primary beam of X-rays converges after reflection from the specimen, passes through a narrow slit, and enters the detector. The detector is driven at twice the speed of the specimen so that the specimen surface is always at θ when the detector is at 2θ . Parallel slits are used normal to the focusing plane to obtain sharp lines. The goniometer drives the detector and specimen at predetermined constant speeds, and the pattern may be recorded using a count-rate meter and strip chart as the scanning proceeds. The resulting chart shows the intensities as a function of reflection angles 2θ (see Plate 2). The pulse-amplitude discrimination method described earlier is used, so that the recorded background is low. To achieve the lowest possible background.

W. Parrish, "Science," 1947

Fig. 15. Principle of diffractometer. Divergent beam of X-rays from narrow line source X passes through divergence slit DS to large flat or curved specimen S . Diffracted beam converges at receiving slit R and continues to counter tube placed beyond antiscatter slit E . Parallel slits P limit beam divergence in plane normal to axis of rotation θ of specimen, and are normal to orientation used in X-ray spectrograph of Fig. 9. Distances X to O and O to R must be equal.

Powder-camera film (upper) and diffractometer recording (lower) of tungsten powder pattern obtained with nickel-filtered copper X-rays. Miller indices are shown for each reflection. Exposure time for film and recording time for chart were both $2\frac{1}{4}$ hours.

X-ray powder photographs obtained with copper-target X-ray tube. Top to bottom: aluminum, unfiltered; quartz with nickel filter on X-ray tube window; quartz with nickel filter strip on bottom of film; lead nitrate; brass wire, showing typical drawn-wire texture (uneven intensities on rings and symmetrical spots around 0° hole).

the diffractometer may also be used with a transmission specimen followed by a curved-crystal monochromator. It is evident that precise measurements may be made much more easily with counter tubes than with film, particularly with manual settings on any of the sections of the pattern that are of particular interest. Quantitative measurements thus become possible.

Determination of Miller Indices.—The atoms or molecules in a crystalline substance are arranged in a symmetrical three-dimensional pattern in which an atom or a group of atoms is repeated by the symmetry of the crystal along straight lines throughout the crystal. This is shown schematically in Fig. 16, in which the array of points and light lines outline a rectangular two-dimensional lattice or framework of one type of ideal crystal. In a real crystal there would be many other sets of planes, including planes parallel to the paper. The smallest group of atoms having the symmetry of the entire lattice pattern is called the unit cell, which in this case has edges parallel to and lengths equal to a and b .

Fig. 16. Two-dimensional lattice, showing Miller indices of several sets of parallel planes. The c -axis is normal to

The traces of the various atomic planes normal to the paper are indicated by the heavy lines. Crystallographers identify these planes in a simple manner. For a given set of planes the number of lines crossed from one lattice point to the next along a are counted, and the procedure is repeated along b (and c). The resulting small whole numbers, designated h , k , l , are known as the Miller indices of that set of planes. Thus the Miller indices of the lines in the lower right-hand corner are (31) , and if they represent planes normal to the paper and thus do not intersect c , the Miller indices are (310) .

The spacings, d , between the planes are related to the Miller indices and the edge lengths of the unit cell. For crystals of the cubic sys-

tem, the three crystallographic axes are normal to each other, have the same length, and

$$d = a / (h^2 + k^2 + l^2)^{1/2} \quad (7)$$

The assignment of Miller indices to each of the reflections in the X-ray pattern is called indexing the pattern and is often an important procedure. This is illustrated for the tungsten powder pattern shown in Plate 2. In this case $\text{CuK}\alpha$ radiation, $\lambda = 1.542 \text{ \AA}$, was used and the first reflection observed at $40.30^\circ (2\theta)$. From Bragg's equation $d = 2.238 \text{ \AA}$, assuming $n = 1$. It was known that a was approximately 3.165 \AA and from equation 7, $(h^2 + k^2 + l^2)^{1/2} = 1.4$. Two of the three Miller indices must be one, and the third zero. (It cannot be determined from the powder pattern whether the indices are 110 , 101 , or 011). To check if a is correct, a high-angle reflection, 400 observed at $153.59^\circ (2\theta, \text{CuK}\alpha_1)$, may be used. From Bragg's equation, $d = 0.7911 \text{ \AA}$ and from equation 7, $a = 3.1644 \text{ \AA}$.

Relations similar to equation 7 exist for the other five crystal systems. Various types of tables and charts are available to facilitate the indexing procedure. The complexity (that is, the number of reflections) of powder patterns increases rapidly with decreasing crystal symmetry and increasing unit cell size, and hence the indexing of patterns of substances belonging to the tetragonal, hexagonal, and orthorhombic systems becomes more difficult; however, it can usually be accomplished. Patterns for substances belonging to the monoclinic and triclinic systems are very difficult to index and often require elaborate computer programs; in these cases data from single crystals also are usually required to supplement the information from the powder pattern.

Identification of Crystalline Solids.—One of the most useful and important applications of the X-ray powder-diffraction method is in the identification of solid crystalline substances. The basis of the method is the fact that each substance gives a characteristic X-ray pattern, and no two chemically distinct substances give identical patterns. The positions of the lines and their relative intensities do not vary for a given set of experimental conditions. Hence, if the unknown substance gives the same X-ray pattern as a known substance, the identification is complete. The powder pattern establishes the identity of a substance with the same certainty that fingerprints identify a person. The method is rapid and inexpensive (aside from the initial cost of the equipment), and it requires only a small amount of the sample. The pattern results from the crystal structure (arrangement of the atoms) rather than from the constituent elements of the substance, and if the specimen contains a mixture of several crystalline substances, each produces its own characteristic pattern.

Identification of unknown substances is made by comparing the pattern of the unknown sample with that of a known substance. A file of reference substances is necessary. For this purpose the American Society for Testing Materials, Philadelphia, Pa., publishes a catalogue of X-ray data obtained from the literature. The file now contains data on many thousands of substances, including minerals, metals and alloys, and inorganic and organic compounds, and is continually being expanded. To facilitate identification, the data cards are arranged according to the d -spacings of the three most intense lines of the pattern.

Substances with the same crystal structures give similar X-ray patterns, with small changes in the spacings and intensities of the lines. The similarities are usually clear enough to be revealed by visual comparison of the patterns. Such information is useful in relating substances that have markedly different chemical compositions. Fig. 17 shows the X-ray patterns of diamond (car-

Fig. 17. Powder patterns (schematic) of isostructural and polymorphic substances.

bon), silicon, sphalerite, and wurtzite.¹ Every atom in each of the first three substances is surrounded by four other atoms, and their structures may be represented as follows:

Many other basic structure types have been revealed by X-ray analysis.

Some substances of the same chemical composition may occur in two or more different atomic arrangements called polymorphic forms (see CHEMICAL CRYSTALLOGRAPHY). Since the atomic arrangement is different, the X-ray patterns will be different even though the chemical composition is the same. This is shown by comparing the patterns of sphalerite (the cubic form of ZnS) with those of wurtzite (the hexagonal form) given in Fig. 17. There are many well-known cases of polymorphism; for instance, diamond and graphite, both carbon, and glass and quartz, both silicon dioxide. Different heat treatments or slight changes in chemical constitution may cause different forms to occur, the physical properties of which may be quite different. X-rays are extremely useful in distinguishing between these forms.

¹ Figs. 17 and 18 are schematic drawings. The positions of the lines are those obtained with CuKα X-rays, and the relative intensities are indicated by the heights of the lines.

Solid Solutions and Mixtures.—In addition to the gross features discussed above, small changes may occur in the X-ray pattern that reveal important facts useful for the analysis of matter in the solid state. Consider the simple X-ray patterns of the metals nickel and copper (Fig. 18). Since

Fig. 18. Powder patterns (schematic) illustrating differences between pure substances, a solid solution, and a mixture.

both have the same structure, they give similar X-ray patterns that differ only in the spacings of the lines. The radius of the nickel atom is somewhat smaller than that of the copper atom (1.25 Å and 1.28 Å, respectively). The atomic planes of nickel are closer together and thus the d -spacings are smaller. The X-ray patterns show the nickel lines occurring at larger 2θ angles, which correspond to smaller d values. Note that the lines occurring at high 2θ angles are shifted by relatively larger amounts than the lines at small 2θ angles. The reason for this is predicted by the Bragg equation, which, after differentiation, may be written

$$\frac{\Delta \theta}{\Delta d} = -\frac{\tan \theta}{d} \quad (8)$$

This equation shows that the shift in line position, $\Delta \theta$, due to a change of lattice spacing, Δd , increases as the tangent of the angle and reaches a maximum at $\theta = 90^\circ$ and $2\theta = 180^\circ$, where $\tan \theta = \infty$. The high-angle lines occurring in the so-called back-reflection region of the pattern are most useful in determining changes in the lattice spacings.

Substitutional Solid Solutions.—Between the patterns of the pure metals presented in Fig. 18 is a pattern labeled $\text{Ni}_{50}\text{Cu}_{50}$, which represents a solid solution of 50 atomic percent of both nickel and copper. If the atomic arrangements of the pure metals in two dimensions are indicated as

the solid solution could be represented as

This is called a substitutional solid solution because the nickel and copper atoms may substitute one for the other and occupy the same relative positions as in the pure metals, although they are randomly mixed. The d -spacings, therefore, are between those of the two pure metals. The lines are shifted in the X-ray pattern by an amount that is dependent upon the composition of the solid solution. A smooth, nearly linear relation exists between the dimensions of the lattice and the chemical composition. The X-ray patterns of simple cases of the type illustrated here permit easy and rapid calculation of the intermediate cases.

Phases.—A single basic structure, called a phase, may extend over wide ranges of chemical composition. In the case just described, the same phase exists for pure nickel, pure copper, and all intermediate compositions. The atomic arrangement is the same for the entire series. Usually, however, only a limited solid solution can take place because the substituting atoms are very different in size, or for other reasons, and the phase will have a limited range of chemical composition. The X-ray method has great practical importance in the determination of phase-composition-temperature diagrams. Such diagrams form the basis for the production of many complicated metals and alloys. If a phase change occurs through heating or change of composition, it is revealed by the X-ray pattern. When the composition of a given phase is altered, the lattice dimensions also change and hence the boundaries in the phase diagram may be determined. This application of X-rays is widely used in the study of binary and ternary alloys, systems of oxides, carbonates, and the like. The application has also been used to detect small amounts of solid solution; for example, in the manufacture of the fluo-

when very small atoms fit into unoccupied interstices of the lattice instead of substituting for atoms in the lattice, so that the lattice dimensions remain nearly the same. An example is the addition of carbon to iron to produce steel. Accurate measurements of the density, in addition to X-ray data, are used to study the process. Density increases with the addition of interstitial atoms, and X-ray data show if specific compounds are formed at certain critical compositions.

Deformed Lattices.—The applications of powder diffraction discussed thus far have been confined to substances in their ideal crystalline state. If the substance is ground to colloidal-crystal size, strained beyond its elastic limit, cold- or hot-worked, rolled, or the like, the resultant lattice deformation has a marked effect on the X-ray pattern. X-rays are of great practical importance in studying these phenomena, and a few examples will be presented in the following paragraphs to show the general nature of these applications.

When a crystalline substance is ground into particles a few microns in size (the beginning of the colloidal range), the resultant X-ray powder lines broaden, the amount of broadening increasing with decreasing size. Although such X-ray patterns will not reveal absolute particle sizes, the technique is quite useful for determining relative sizes and for distinguishing between clusters of particles and true crystallite sizes. The equation

$$t = k\lambda / (b - b_0) \cos \theta \quad (9)$$

gives the basis for the measurement. The crystallite thickness, t , is the dimension perpendicular to the reflecting atomic planes; k is a constant

Fig. 19. Diffractometer patterns of barium titanate, BaTiO_3 . Top, strained crystallites; bottom, strain-free ceramic.

rescent material zinc orthosilicate, in which 1 percent manganese substitutes for zinc.

Interstitial Solid Solutions.—Homogeneous phases known as interstitial solid solutions occur

usually taken as 1; b is the measured width of the diffraction line of the small-particle specimen; and b_0 is the width of the line obtained with particles large enough not to cause line broaden-

ing, both b and b_0 being measured under exactly the same experimental conditions. If the powder consists of small particles whose sizes embrace a large range, the X-ray measurement represents an average value because it is not possible to separate the overlapping broadenings. One application of the method has been the testing of the quality of catalysts. A good catalyst has a large surface area and hence small particle size. If the X-ray pattern is sharp, it is good evidence that the particles are too large.

When a substance is strained, the X-ray lines, particularly those at high angles, become broad and poorly defined. When the strain is removed by appropriate heat treatment (annealing), the lines return to their original sharpness, as shown in Fig. 19. This is a simple procedure to determine the correct annealing temperature. The method is also used to determine the effect of various types of mechanical treatment on the material.

Crystals With Preferred Orientations.—In the foregoing discussion the assumption has been that the crystallites in the X-ray specimen are randomly arranged so that all possible sets of atomic planes have an equal probability of reflecting. If this is not the case and if the crystallites assume certain special orientations, then the relative intensities of the lines of the X-ray pattern will be changed from their correct values; or, in extreme cases, some reflections may disappear, as shown in Fig. 20. The

Fig. 20. Portions of diffractometer patterns of a commercial ferrite ($\text{BaO} \cdot 6\text{Fe}_2\text{O}_3$) for (a) random arrangement of crystallites and (b) oriented crystallites. The 110, 008, 107, and 200 reflections have large differences in relative intensities because of the preferred orientation.

ability of X-ray patterns to elucidate such behavior provides a powerful tool for the study of many practical problems of the orientation of crystallites in fibers, wires, sheets, and foils.

Many electrodeposited metals tend to orient themselves in a preferred manner. For example, when selenium is plated on steel under certain conditions, it shows a marked preference for growing with its c -axis, the axis along the selenium chain of atoms, perpendicular to the steel surface; the a -axes, perpendicular to the chain, are more or less randomly oriented. X-ray diffractometer patterns show a large increase in intensities of reflections from the atomic planes

perpendicular to the c -axis relative to those of planes parallel to the c -axis. The latter are less likely to be in a position to reflect X-rays and may even disappear from the pattern. Electrical conductivity is much larger in the direction along the chain than perpendicular to the chain. The X-ray method affords an ideal way of following the plating conditions required to develop the best selenium electrical elements. Similarly, the magnetic properties of certain ceramic materials are enhanced by placing the powder in a magnetic field prior to firing so that the crystallites are oriented, resulting in the highest possible magnetic susceptibility for the material. X-rays are used to study this process, which cannot be followed with a microscope.

In the manufacture of drawn wire the metal crystals tend to become oriented with respect to the drawing direction but are randomly oriented around the wire axis. An X-ray powder photograph of a wire, therefore, shows discontinuities and marked variations of intensity around the circumference of the X-ray reflection. X-rays are also used to follow the effect of various treatments on the molecular orientation of natural and synthetic fibers such as ramie and nylon. The improved mechanical strength of the fibers and their physical properties can be correlated with the particular alignment of the molecules caused by extrusion and drawing.

The preferred orientation of crystals in rolled metal sheets may be influenced by the manufacturing method. The crystals tend to align with a certain rolling axis and in a particular orientation with respect to the rolling plane. The preferred orientation has a marked effect on deep drawing and similar operations. Careful control of the rolling process by X-ray analysis can produce special orientations, for example, in iron-silicon sheets used in transformer cores. The direction of easiest magnetization of iron-silicon crystals is parallel to the cube axes, and when this direction coincides with the rolling direction, the sheet has a high permeability.

Amorphous Substances.—The X-ray patterns of amorphous materials, such as glasses, resins

Fig. 21. Diffractometer patterns showing devitrification of a glass (95 mole percent SiO_2 + 5 mole percent K_2O) in alpha cristobalite (SiO_2). (a) Powdered, untreated glass (b) material melted and heated $\frac{1}{2}$ minute at 1200°C (c) material melted and heated 5 minutes at 1200°C

and liquids, are distinctly different from those of crystalline substances. The atoms in an amorphous material do not have the symmetrical repeating arrangement so characteristic of crystalline materials. The X-ray patterns of amorphous

materials appear as one or two weak broad bands at small 2θ angles superimposed upon a continuous background. X-rays are therefore not useful in distinguishing between amorphous substances, but are ideally suited to show if a substance is crystalline or amorphous. The test is useful in many practical applications.

The X-ray diffractometer patterns of Fig. 21 show the progress of the devitrification (crystallization) of a silica glass. At the left is the broad diffuse band characteristic of glasses. The middle pattern shows the beginning of crystallization by the appearance of lines of cristobalite, a

pattern shows an increase in the intensity of the lines and further reduction of the band as the devitrification continues.

4. X-Ray Tubes

An X-ray tube consists essentially of a cathode, which is a source of electrons; an anode or target, usually of a pure metallic element; and a means of applying high voltage to drive the electrons to the anode. There are two general types of X-ray tubes: gas-filled and vacuum. In the gas tube, electrons are emitted from a cold cathode by positive-ion bombardment. Gas tubes are not commonly used because their operating characteristics are critically dependent on the accurate control of the small gas pressure, and it is difficult to accomplish this regulation to the degree required for stable operation.

Vacuum X-Ray Tubes.—The principle of the vacuum X-ray tube was developed by Coolidge in 1913, and is the basis for the manufacture of most X-ray tubes now used. Some typical vacuum X-ray tubes are shown in Fig. 22. The electrons are emitted by a hot filament, usually a tungsten wire heated to 2300° to 2400° C, and the emission can be controlled by the filament current independently of the voltage applied to the X-ray tube. When the electrons are emitted, current flows between the anode and cathode. By using a high vacuum and by stabilizing the voltage and X-ray tube current, highly stable operating conditions are obtained, and the voltage and current may be easily selected by the operator. One of the problems in the development of vacuum tubes was to prevent contamination of the target and coating of the windows by tungsten evaporated from the filament. With modern tube technology this difficulty has been minimized.

The hard-glass, cylindrical vacuum-tube envelope is sealed to the metal anode end by means of a special metal-to-glass seal. The seal is an iron-nickel-cobalt alloy having a coefficient of thermal expansion close to that of the glass. The materials in the tube are thoroughly cleaned and outgassed, and an elaborate procedure is employed to assemble the tube, pump it to its required vacuum (a pressure smaller than 10^{-6} mm mercury), and test it. Sometimes a "getter" material such as zirconium is included in the tube. After assembly the getter is activated to absorb the remaining traces of gases that may still be trapped in the tube after sealing. All portions of the tube must be designed with the capability of avoiding electrical failures at the high voltages used. For special researches a demountable tube with associated vacuum system is sometimes used.

The separation of anode and cathode depends

on the design of the tube and on the required maximum operating voltage. For lower-voltage tubes (about 50 or 60 kv) used in X-ray analysis, the separation is of the order of 10 to 35

"Philips Technical Review"

mm, whereas in multisection high-voltage tubes the electrons may travel several feet. The electrons are focused onto a small area of the target called the focal spot, focal area, or focal line. Only a small fraction of the electron beam produces X-rays. The efficiency of X-ray production increases with applied voltage, being less than 0.1 percent at low voltages, about 1 percent at 100 kv; 10 percent at 2 Mv (million volts), and about 50 percent at 15 Mv.

At low voltages most of the electrons dissipate their energy in the form of heat; and provision must be made to cool the anode. This is done either by forced circulation of water or oil

in contact with the outside of the target, or by air cooling. Metals such as tungsten, molybdenum, and copper are satisfactory targets because they have the high thermal conductivity or melting point and the low vapor pressure required to withstand the high localized heating in the focal spot.

The size of the focus and the method of cooling determine the maximum permissible power that may be applied to the tube. For example, a copper-target, air-cooled diffraction tube with a focus size of 1 by 10 mm may be operated continuously at about 100 watts (total load) or 10 watts per square millimeter (specific load). By water-cooling the same tube the power may be increased safely by a factor of 7 to 10. A further similar gain may be achieved by making the target in the form of a disk about 2 or 3 inches in diameter with the focal spot near the edge. By rapidly rotating the target a cooled portion is always presented to the electron beam, but the position of emitted X-rays remains stationary. If the focus is greatly reduced in size, say below $50\ \mu$ ($\mu = 1\ \text{micron} = 0.001\ \text{mm}$), the specific load can be of the order of 1,000 watts per sq mm. For a $1\ \mu$ focus the specific load can be further increased; it is usually limited by the electron emission from the cathode rather than by target cooling.

The X-rays emitted by the tube are generated very close to the surface of the target. For the soft X-rays it is necessary to provide one or more low-absorbing windows near the focal spot to transmit the X-rays out of the tube with a minimum loss of intensity. For this purpose mica about $10\ \mu$ thick or beryllium from 50 to $1,000\ \mu$ thick is frequently used. The tube is usually mounted in an X-ray-proof metal housing (with a shutter over the window), and the high-voltage cable is generally shockproof to minimize the hazards involved in using such equipment.

The apparatus for controlling and operating the X-ray tube usually consists of electronic regulators to stabilize the X-ray tube voltage and current, and meters to read the values; rectifier tubes and a capacitor to convert the a-c line power to d-c constant potential; a variable autotransformer (Variac) calibrated in kilovolts for selecting the voltage; a filament-heating transformer; protective circuit breakers and interlock switches to prevent contact with the high voltage; a water supply for cooling the tube and transformer, with associated cutoff switches in case the water flow falls below a preset amount; and the high-voltage transformer. For X-ray analysis the entire assembly is usually housed in one metal cabinet.

High-Voltage Sources.—X-ray tubes for diffractometry and spectrography are usually operated below 60 kv. For radiographic examination of thick or highly absorbing materials it is necessary to use higher voltages because the penetrating power increases with voltage. X-ray tubes have been developed that operate up to about 400 kv. For voltages up to 1 or 2 Mv it is necessary to use multisection tubes in which the X-rays pass through the target and emerge from the end of the tube.

The Van de Graaff generator (see PARTICLE ACCELERATOR) has been used as a source of X-rays above 1 Mv. The electrostatic charge is carried by a rapidly moving insulated belt to the high-voltage terminal, which is connected to the cathode of a multisection X-ray tube.

The linear accelerator has been used for voltages of the order of 6 to 8 Mv. It consists of a wave guide with an axial electric field in which the electrons from an electron gun are accelerated using radio-frequency power supplied by a klystron (see ELECTRONICS—Microwave Electronics). The electron energy increases at the rate of about 1 Mv per foot, and the high-energy electrons strike a transmission-type target placed at the end of the wave guide.

The betatron has been used to generate X-rays in the 15 to 30 Mv range. Electrons are injected tangentially into an evacuated doughnut-shaped glass tube that is surrounded by a magnetic field. The field guides the electrons around the circle and continually accelerates them. After they have achieved the desired energy they are magnetically guided out of the circular field to strike a target and produce X-rays.

5. X-Ray Microscopy

The possibility of using X-rays for microscopy would appear attractive because of the poten-

Fig. 23. The five types of X-ray microscopes. The upper three employ conventional X-ray tubes, while the lower two require demountable point-focus tubes with electron-focusing devices.

tially great resolving power that would be possible using short-wavelength radiation. Fig. 23 shows the five types of X-ray microscope that have been developed. Although the problem of designing X-ray microscopes has been intensively studied, their development has been slow because of technical difficulties and the special problems involved in accurately focusing an X-ray beam. It is not possible to make lenses for X-rays, because for X-rays the refractive indices of all substances are slightly less than one. Hence it is necessary to reflect the X-rays to form an image. (Here the word "reflection" is used in its true meaning and not as a synonym for diffraction, as was the case in several previous instances.)

At angles above grazing incidence X-rays penetrate the surface and are absorbed or transmitted, as explained in section 2. *X-Ray Spectrochemical Analysis* (X-Ray Absorptiometry). However, X-rays are nearly totally reflected at very small glancing angles. The critical angle for total reflection increases with wavelength and atomic number of the reflecting element. It is generally less than 30 minutes of arc and reaches only 3° for 8.3-A X-rays reflected from gold. The reflecting surface must be a precisely formed concave surface of large radius finished to about 10 Å, which is at least an order of magnitude finer than the best optical surfaces. In addition to the great difficulty of preparing such surfaces, the images suffer from various aberrations that limit definition. The resolution that has been achieved is about the same as that of a good optical microscope, and the exposure times are long, often an hour or more. Diffraction from doubly curved crystals has also been used in attempts to make a microscope, but the results have not been any more successful than those using mirrors because of the limited perfection and low reflecting power of the crystals.

The great penetrating power of X-rays, and the fact that their absorption is dependent on the elemental composition of the specimen, make it possible to use X-rays for new types of microscopic studies. The methods and results are totally different from those of optical and electron microscopy. The two methods commonly used, contact and projection microradiography, are described below. They are similar to normal X-ray radiography in that the X-ray transmission image of the object is recorded on film.

Contact Microradiography.—The simplest method of X-ray microscopy is known as contact microradiography. In this method a thin specimen is placed directly on a fine-grained photographic plate and exposed to X-rays. The specimen is removed, and after the plate is developed it is examined with an optical microscope. Selected regions are enlarged photographically because there is no magnification of the original X-ray image. The resolution is about $1\ \mu$ (with special care $0.2\ \mu$ has been achieved), and is determined primarily by the grain size of the photographic emulsion and the resolving power of the optical equipment used for the enlargement. The specimen should be of the order of 1 or $2\ \mu$ in thickness and in close contact with the plate to avoid penumbra effects; however, good results have been obtained with specimens over $200\ \mu$ thick. The contrast on the plate is determined by the X-ray absorption in the specimen. Thus for biological specimens, which con-

sist of low-atomic-number elements and hence have low X-ray absorption, soft X-rays (0.5 to 5 kv) are used, while for metallurgical specimens more penetrating X-rays (up to 30 kv or more) are required. The field of view in this method is larger than in the projection method.

Projection Microradiography.—If the focal spot of the X-ray tube is extremely small, the specimen may be placed close to it and at some distance above the photographic plate to obtain a magnified image. This method is called point-projection microradiography. The magnification is determined by the ratio of the distances from the focal spot to specimen and specimen to plate. Initial magnifications of 10 to $100\times$ may be obtained and further magnification may be done photographically, as in contact microradiography. The definition of the image is determined primarily by the size of the focal spot, which should be of the order of $1\ \mu$ in diameter. If a normal-size focal spot is used with a very fine pinhole (camera obscura), the intensity is generally too low for practical use because the specific loading of the target (see section 4. *X-Ray Tubes*) is relatively low in such cases. With extremely small focal spots the specific loading is much greater, but the demountable tubes used require a special cathode, electron-focusing system, and vacuum arrangement.

Microradiographic Applications.—Both the contact and the projection methods give sharply imaged photographs. The optical microscope has only a small depth of focus at high magnification and hence cannot be used for stereophotographs; however, it is possible to obtain remarkable three-dimensional pictures with X-rays. Two separate exposures are made, the specimen being tilted between exposures. When the pair of plates is observed with a stereo viewer the spatial relationships are seen clearly and can be measured. This method has been used to obtain photographs showing details of the structure of such things as plants, insects, and paper that could be obtained in no other way.

The blackening of the film is dependent on the elemental absorption of X-rays in the specimen, and hence it is possible to make quantitative analyses on very small sample volumes with moderate precision. A step-wedge set of filters of known absorption is placed beside the sample and both are simultaneously exposed to the X-ray beam. The absorption in different parts of the sample can be calculated by comparing the film density at different parts of the microradiograph with the film density of the step wedge. Arne Engström has used the method in biological and medical studies with great success. As little as 10^{-12} gram of an element has been determined in samples where the concentration was as small as 1 percent with an accuracy of 5 to 10 percent.

The circulation of blood in the ear of an anesthetized rabbit has been studied by injecting an X-ray-opaque suspension into the blood vessels and making serial exposures (microangiography). Living insects, botanical specimens, human skin, liver and kidney sections, nerve cells, and other materials normally studied in pathology and histology are but a few examples of the enormous variety of biological materials investigated by microradiography. There are also many inorganic applications, such as the location and identification of inclusions, precipitates, and segregations in steels and light-metal alloys. The diffusion of one metal into another

can be followed. The X-ray study of fossils, such as foraminifera and other microspecimens, often reveals details of the internal arrangement that cannot be seen by other methods. The distribution of fibers and filler in papers has been extensively studied by microradiography. (See Plate 3.)

6. Radiography and Fluoroscopy

The use of X-rays to obtain photographs of the interior of objects that are opaque to visible light was applied shortly after Roentgen's discovery of these rays. The method is now widely used in industrial and medical applications. The apparatus is basically simple. The object to be photographed is placed between the X-ray tube (or gamma-ray source) and the film cassette. The image shows the X-ray transparency of the three-dimensional object projected onto the flat film. Regions of high X-ray absorption in the specimen cause less blackening of the film than do regions of low X-ray absorption.

In fluoroscopy the apparatus arrangement is identical to that of radiography, except that the film is replaced by a fluorescent screen to permit direct viewing of the image. The advantages over radiography are that both the film developing time and the cost of the film, which may be as much as one half of the total X-ray inspection cost, are eliminated. The disadvantage is that the image has poorer quality because of the graininess and diffusion in the fluorescent screen. In photofluoroscopy the image on the fluorescent screen is photographed with a small camera; this has the advantage of a permanent record, but the small photograph has poorer quality than the large direct photograph. The film is sometimes placed between a pair of fluorescent screens so that the light from both screens serves to intensify the image on the film, although this causes some loss of definition. Xeroradiography, in which an electrostatically formed image is obtained, has been used in place of film and fluorescent screens in certain applications.

For a given X-ray tube voltage, the product of the tube current expressed in milliamperes (ma) and the exposure time in seconds is referred to as the exposure, which is expressed in milliamperere-seconds (ma-sec). In radiography the continuous radiation is used. The X-ray output of the tube may be increased by increasing the voltage or the current, but the penetrating power can be increased only by raising the voltage. Since monochromatic X-rays are not used and since the object may have a non-uniform thickness, the exposure times can be calculated only roughly, and a few trial exposures may be required to obtain the optimum contrast. The elemental composition of the object is most important in determining exposure time and the selection of the X-ray tube voltage. For example, 200-kv X-rays are transmitted with approximately equal intensity through 1.2 in. of steel and 0.1 in. of lead.

The same geometric laws of shadow formation that are used for visible light apply to X-rays. Hence the sharpness of the image on the film is dependent on the size of the X-ray focus, the thickness of the object being X-rayed, the closeness and parallelism of the object, and the film. The smaller the focus and the thinner the object, the sharper the image. The definition becomes distorted when each point of the object casts a shadow that overlaps with the shadows from adja-

cent points. Increasing the distance between the focus and the film aids in improving the definition, but the intensity at each point in the photograph is reduced by the inverse square of the distance.

Scattering, diffraction, and fluorescence originating in the object, the film cassette, portions of the apparatus, or floor and walls of the room add to the background on the film, thereby reducing the contrast. Scattering is reduced by means of lead-foil screens surrounding the film to absorb the softer radiations, the use of a thick lead sheet on the back of the film cassette, and the use of various diaphragms to limit the beam.

In order to obtain perspective, it is necessary to make a pair of radiographs by moving the X-ray tube a distance equal to the separation of the eyes and to view the pair with a stereoscope.

Applications.—Radiography is used in a large variety of applications, such as to find gas holes in aluminum-alloy castings for aircraft; to inspect welds; to exercise quality control of electronic components such as vacuum tubes, resistors, and printed circuits; to detect porosity and shrinkage cavities in castings; to locate segregations in alloys; and to find cracks, ruptures, inclusions, and other defects in metallic bodies. (See Plate 4.)

Flash-radiographic systems have been developed that can photograph a rapidly moving object in a fraction of a second. A special X-ray tube with a field-emission cathode is used in conjunction with a capacitor charged to the required voltage. The capacitor is discharged by a triggering electrode, causing current to flow to the anode and produce a high-intensity burst of X-rays.

Image Intensifier.—The image intensifier is an evacuated glass tube in which an X-ray fluorescent screen and photocathode are mounted, as shown in Fig. 24. X-rays entering the tube strike the fluorescent screen, and the emitted light causes electrons to be released from the photocathode. The number of electrons released from each point on the cathode is proportional to the luminous intensity of the screen at that point and hence also proportional to the incident X-ray intensity.

M. C. Teves, "Philips Technical Review," 1955

Fig. 24. Schematic cross section of image-intensifier tube. O, object exposed to X-rays; D, support carrying R, the first fluorescent screen, and K, the photocathode; A, hollow anode surrounding FI, the viewing fluorescent screen; M, viewing microscope; W, conductive coating on interior of evacuated glass envelope.

An electric field focuses the electrons so that the image is reproduced, reduced by a factor of about 9, on the viewing fluorescent screen. The electrons cause visible fluorescence and the luminous image can then be viewed by a simple microscope or binoculars with about $9 \times$ magnification, so that the image is seen in its original size. By comparing the roentgenographic study (below right) with one of an authenticated Stuart work, similarities and differences were noted, and it was established that this was not the work of Stuart.

image, however, is much brighter than the original image on the first fluorescent screen. This intensification results from two factors. First, the high voltage applied between the photocathode and viewing screen imparts high energy to the electrons, thereby increasing the fluorescence intensity on the viewing screen to 10 to 15 times that on the first fluorescent screen. Second, the size of the image on the viewing screen is reduced by 9°, so that the light is emitted from an area 81 times smaller than the first screen. The product of these two factors gives a gain in intensity of from 800 to 1,200, and the image resolution is as good as that of the fluorescent screen normally used in fluoroscopy. Hence it is possible to decrease greatly the normal X-ray dose received by a patient in, say, chest fluoroscopy and also enable the patient to be examined in a room with moderate lighting without the physician requiring eye adaptation. The increased intensity also makes possible X-ray motion pictures without excessive radiation dose to the patient. The image intensifier has also been used in many types of industrial radiographic examinations.

Laboratories, Irvington on Hudson, N.Y.

7. Medical Uses of X-Rays

With the advent of X-rays mankind gained one of the most powerful tools in the long history of medicine. For the first time it became possible to peer into the innermost recesses of the body without the aid of the surgeon's scalpel. It also became possible to apply medical diagnostic methods to hitherto completely inaccessible areas of the human body by painless, efficient techniques. Few discoveries have had such far-reaching effects and universal application as that of Roentgen. His X-rays are employed all over the world and have made an immeasurable contribution to the early diagnosis, control, and treatment of disease. It is equally true that the full possibilities of X-rays are not yet understood and that increasing uses of them may be achieved in the future.

The term "radiology" is used to designate those branches of medicine concerned with X-rays, other ionizing radiations, and radioactive substances. From the beginning the diagnostic uses of X-rays have been chiefly divided into fluoroscopic and radiographic techniques. X-rays are also employed as a method of treatment and have a wide application ranging from the acne or pimples of the adolescent to the widely prevalent bursitis or shoulder pain and deep-seated cancers in remote areas of the body. See **RADIOTHERAPY**.

Fluoroscopic Techniques.—Frequently, fluoroscopic examination of portions of the human body precedes other X-ray methods and constitutes a way of examining the body in motion. It is accomplished by placing the patient between the X-ray tube and a special fluorescent screen. When the rays strike the screen they cause the particles in the screen to glow strongly enough to be easily seen in a completely darkened room. When the patient is placed between the X-ray tube and the screen, the difference in density of various parts of the body causes a varying shadow to be cast on the screen, enabling the observer to distinguish between different parts of the body. This effect is further enhanced if the observer has accommodated the pupils of his eyes by wearing special goggles before going into the darkroom. In addition, various techniques are adopted to accentu-

ate contrast in this method, such as the use of radio-opaque solutions that cause a dense shadow to be cast on the screen.

One of the most frequent uses of fluoroscopy is in the investigation of the alimentary canal or digestive system. This method was pioneered by Dr. Walter Bradford Cannon (1871-1945). In order, for example, to diagnose disease of the esophagus or swallowing tube, the patient is given a solution to drink that is sufficiently dense to cast a clear-cut shadow on the fluorescent screen. The opaque medium usually employed here and for other parts of the digestive system is barium sulphate. The patient stands behind the screen in the darkroom holding a glass of barium sulphate, and the observer takes a position in front of the screen with the controls of the X-ray unit at hand. The patient is then told to drink from the glass, and on the screen the observer is able to see the entire swallowing process and follow the barium into the stomach. If there is any adverse condition affecting the esophagus, such as inflammation, a swallowed bone, or a tumor, the drink of barium sulphate will outline the effect of the condition on the structure of the esophagus. For example, if the patient had swallowed, whole, a chunk of meat that had lodged midway down the esophagus, the barium sulphate would stop at that point and indicate just where the meat was located. If it became necessary to operate, knowledge of the exact location of the obstruction would be of extreme value to the surgeon.

A similar technique is employed for investigation of the stomach. The stomach is filled with barium sulphate and outlined on the fluorescent screen. The motion and action of the stomach are clearly seen, and abnormalities of function as well as structure may be identified. Examination of the large colon or intestine is also carried out by this method. In this case the barium sulphate is administered as an enema from the rectum and the observer is able to visualize the rectum and the colon. Many persons have been saved from cancer by having the curable conditions that precede cancer in the colon discovered and corrected in time.

Examination of the heart as a moving organ is best done with the fluoroscopic screen. Where previously doctors labored with listening and tapping aids to draw a mental picture of their patients' hearts, it now is possible to see the heart in its functioning state and to watch it expand and contract. At the present time this method has become so well accepted that it is a rare heart specialist who does not have a fluoroscopic device in his office for this purpose. At the same time that the heart is examined the lungs are inspected and the movement of the diaphragm is observed.

The fluoroscopic screen has different uses for the various specialties in medicine. The orthopedic or bone surgeon checks fractures with it. The industrial or military surgeon uses it to locate metallic fragments resulting from industrial accident or military gunshot. The pediatrician or baby doctor looks for an inhaled candy ball or toy. The chest physician searches for early evidence of lung tumor. This partial list of present uses of fluoroscopy is continually being expanded.

Radiographic Techniques.—Techniques to obtain a picture of some part of the interior of the body are now standard medical practice all over the world. These methods differ from fluoroscopy in that a still picture is obtained, with no indication of the motion of the part X-rayed except

when enough separate films are taken to simulate a cycle of motion. These stills, however, play a most important role in medical diagnosis and generally show a finer detail throughout than it is possible to obtain on the fluoroscopic screen.

An enumeration of all the uses of X-ray films would be extremely lengthy. Suffice it to say that there is no part of the body that is exempt from the probing of the X-ray eye and that medical diagnosis has become markedly dependent upon X-ray findings, so much so that a complete medical specialty has grown up around Roentgen's discovery and doctors devote years to training in the various aspects of X-ray technology.

The uses of special substances to show organs in the body reach into many branches of medicine. The kidney specialist may wish to determine the location and effect of a kidney stone. There are available to him several medications that, when injected intravenously, will render opaque the internal kidney structures as well as the tubes leading to the urinary bladder and the bladder itself. In some cases he will inject the contrast medium through an instrument inserted from below into the bladder. X-rays taken at this time show the structures in considerable detail and enable the physician to locate the site of disease.

The gallbladder is a relatively frequent offender. A contrast medium has been perfected that, when taken by mouth, will render the gallbladder dense enough to be seen on an X-ray film. In this way gallbladder function and the possibility of stones are determined. Even after the gallbladder is removed there are ways of studying the remaining bile passages with contrast media and X-ray films.

The problem of sterility, or inability to bear children, has come under X-ray observation. The specialist may inject material that will render the female reproductive tract opaque and show the structures on X-ray film. In this way the exact cause of sterility may be found and its correction attempted. Following conception, X-rays are used to measure the female pelvis in order to determine whether the unborn infant can pass safely down the birth canal. By means of this technique, many children are now delivered safely, whereas formerly they might have hemorrhaged intracranially and as a result been born with brain damage and paralysis because of small maternal passages.

X-ray studies have been of great assistance to the neurologist and neurosurgeon. X-ray photographs of the skull and spine may point the way to the diagnosis. Specialized techniques are also available. For example, in the diagnosis of spinal-column disease the specialist may inject an opaque solution and watch its passage up and down the spinal canal with the fluoroscope. He may also inject air for special brain studies, especially to diagnose and locate brain tumors.

Preventive medicine has benefited vastly by the employment of X-ray techniques. Chest surveys for the early diagnosis of tuberculosis, with resultant decreased time of treatment and diminished risk to contacts, are a commonplace. This screening technique has been applied in government, industry, the armed services, and community life.

Many advances have been made in refining techniques for the purpose of early diagnosis, especially in the heart and cancer fields. Methods of showing the inner structures of the heart are of particular importance to children born with de-

fective hearts who had previously been condemned to ever-constricting activity and ultimate death. These cases include the so-called blue babies, babies with a faulty circulation of the blood that causes them to have a bluish cast. Diagnostic methods now make possible an early determination of just where the heart defect may be and enable the surgeon to utilize appropriate surgical techniques.

Another development of note enables the radiologist to take films at designated levels in the body in an attempt to determine more precisely the site of disease. This technique is known as laminography and is particularly important in the chest, where tuberculous cavities must be located precisely for the chest surgeon. For the further determination of depth and for the localization of objects within the body, a stereo technique called stereoroentgenology is employed. In this method, two films are exposed following a small shift in position of the X-ray tube corresponding to the distance between the radiologist's eyes. The object being X-rayed remains stationary. The two films are then viewed in a stereoscope so that the illusion of depth is achieved. This method is used, for example, to localize a foreign body in the skull preparatory to surgical removal.

The X-ray apparatus used for radiography and fluoroscopy is undergoing constant change and there is a steady flow of specialized accessories designed to facilitate more modern procedures. One of the most notable of these is an electronic device that increases the brightness of the fluoroscopic image. See also VETERINARY MEDICINE—Practice (Specialization): Radiology.

Radiation Hazards.—The hazards of X-rays are being reemphasized in this age of atomic radiations. Improper use may result in damage being done to all personnel concerned, and the history of radiology is replete with its martyrs. This means, in effect, restricting X-ray procedures to those types of disease in which the expectation of useful and pertinent information is a reasonable one. In addition, there should be full employment of protective devices and techniques directed principally toward reducing the amount of radiation received by the patient, the physician, and the technical staff. These include the proper use of leaded shields, modern equipment, and skilled technicians.

The government has begun to exert its influence on safety requirements, and inspection for compliance with existing regulations may become a routine occurrence. At the same time it must be stated that the preeminent position of the X-ray method in the diagnosis of disease should not be downgraded because of radiation hazards. In the hands of skilled technicians and well-trained radiologists, the risks can be reduced to a minimum and the great benefits retained.

XY COMPANY, the popular name of the New North West Company formed in Canada in 1798 by a union of Montreal fur firms and discontented North West Company men. The new company marked its goods with the letters XY. After a bitter struggle which was injurious to both enterprises, the XY Company was absorbed into the older company in 1804, receiving a one-fourth interest in the new combine.

XYLEM, zī'lēm, that part of the vascular system of the higher plants which functions in the conduction of water and various substances in solution from the roots to all parts of the plant. Xylem also gives major support to the plant body in woody plants and serves to some extent in food storage. The trunks of trees consist largely of xylem.

Xylem is a complex tissue. In the mature tissue, part of the cells are living; others are mere cell skeletons. The basic cell type is the tracheid, from which are derived by evolutionary specialization the fiber and the vessel element. Fibers, the major support of xylem, have very thick walls. The vessel element is the unit of a series that, united, forms the pipeline-like vessel. Associated with these nonliving cells in the formation of a longitudinal system are rows of small living cells, the xylem or wood parenchyma. Other living cells, lying in radial sheets, form a transverse system, the xylary or wood rays, often conspicuous in the grain of wood.

Xylem, in mass or in strands, is present in all parts of the plant: stem, roots, leaves, floral organs, fruits. In tree trunks, in the older branches, and

in the older roots of woody plants, the first-formed xylem ultimately ceases to function except as support, and becomes heartwood. Heartwood, especially important as lumber, has no living cells and is permeated by preservative, and other substances that commonly give it a dark color, distinguishing it from the outer, younger sapwood.

XYLOGRAPHY. See WOOD ENGRAVING AND WOODCUT.

XYLOPHONE, zī'lā-fōn, a musical instrument of the percussion family. As the name suggests (literally "wood sound"), it consists of tuned bars of hardwood in keyboard arrangement, graduated in length to provide a chromatic scale of three to four octaves. The bars have metal resonators and are mounted upon cords on a tablelike frame. The performer stands and uses special hammers or sticks (usually wooden) to strike or sound the wooden bars.

Primitive forms of the modern xylophone were developed in Asia and Africa and introduced into Europe during the Renaissance period under various names, including *Strohpfedel* or strawfiddle. During the 19th century the special virtuoso and tonal qualities of the instrument became widely known. Camille Saint-Saëns made effective use of the xylophone in his popular symphonic poem *Danse Macabre* (1874). Gustav Mahler, Igor Stravinsky, Dmitri Shostakovich, and numerous other 20th century composers have given it a prominent role in the symphony orchestra. Its importance in popular music is overshadowed by the marimba (q.v.), a similar instrument closely identified with Central American music, and the vibraphone (q.v.), used in dance bands and jazz groups.

WILLIAM BRACY.

XYLOPIA, zī-lō'pī-ə, a genus of some 160 species of trees and shrubs in the predominantly tropical family Annonaceae. The generic name is a modification of the pre-Linnaean name *Xylopicrum*, which was derived from the Greek *xylos*, wood, and *pikros*, bitter, referring to the taste of the wood. *Xylopi* is unique in that it is the only annonaceous genus (of about 120 in the family) with species growing in the tropics of the New World, Africa, and Asia. The leaves are often coriaceous, oblong to elliptical, entire-margined, and usually borne in two ranks. The flowers, borne singly or in clusters, have a distinctive three-angled corolla comprised of two whorls of six fleshy, elongate petals. The three inner petals, slightly shorter than the outer three, have a swollen concave base which fits compactly over the numerous minute stamens and carpels borne on the enlarged receptacle. The anthers on the stamens are transversely septate; the pollen grains usually are shed in groups of four, and thus are visible to the naked eye. The carpels are borne in a craterlike depression in the center of the receptacle; after fertilization the fruits become subcylindrical elongate berries containing two rows of seeds characterized by ruminated endosperm.

The black dried fruits of an African species (*X. gethiopica*) have been called "Guinea peppers," and were once of commercial importance in Europe as a tangy condiment and/or drug. At

present the fruits are used locally by native tribes as a cough medicine and purgative. The dried fruits of three Brazilian species (*X. aromatica*, *X. sericea*, and *X. frutescens*) also have a limited pharmaceutical use; for example, in treatment of fevers. The wood of *X. frutescens* and *X. sericea* is relatively dense (specific gravity 0.626), and is used by Indians in house construction. The bark of these species also has a limited use for cordage and in making crude textiles. The wood of *X. aethiopica* is quite flexible and has been described as termite-proof. It is utilized for bows in the area formerly called Togoland, as well as for house posts, masts, and boat paddles throughout west-central Africa.

XYZ CORRESPONDENCE, in United States history, the name given to the reports made to President John Adams by an official commission which was rebuffed in its efforts to negotiate a treaty of commerce and friendship with France in 1797–1798. The attendant circumstances, known as the XYZ Affair, marked a low point in relations between France and the United States and brought the two nations close to war.

The French Directory had been angered by the conclusion in 1794 of Jay's Treaty (q.v.), which resolved differences between England and the United States, and in retaliation had stepped up its harassment of American shipping. In the 12-month period ending in June 1797, French ships had captured 316 vessels flying the American colors. In an effort to restore amity with the Continental power, President George Washington dispatched Charles C. Pinckney, a Southern Federalist, to Paris in December 1796. The Directory flatly rejected this conciliatory gesture. It not only refused to recognize the envoy but even threatened to arrest him if he did not quit the country, and Pinckney, incensed by the insult, departed for the Netherlands.

This serious rupture in diplomatic relations between the former wartime allies confronted John Adams when he assumed the presidency the following March. Determined to avoid the open conflict which threatened, he sent to Paris a three-member commission composed of Pinckney, John Marshall, another Federalist, and Elbridge Gerry, a Massachusetts Republican and Francophile. Soon after their arrival on October 4 they were received unofficially by the French foreign minister, Charles Maurice de Talleyrand-Périgord, but then weeks passed with no word on when an audience with the Directory might be expected. During this time, through the contrivance of Talleyrand's friend Mme. de Villette, the Americans were approached by three agents of the foreign minister—Jean Conrad Hottinguer, a Swiss; a Mr. Bellamy, an American financier living in Hamburg; and Lucien Hauteval, also a Swiss (designated mysteriously as X, Y, and Z, respectively, in President Adams' subsequent report to Congress). As a price for negotiations between the two governments, the French emissaries demanded a bribe of about \$250,000 (to be paid to Talleyrand), a large official loan from the United States, and an apology for certain references to France in a recent

speech by Adams. Although bribery was not an unknown adjunct to the diplomacy of that day—particularly where Talleyrand was concerned—the Americans found the proposition totally unacceptable. (Pinckney's supposed retort, "Millions for defense, sir, but not one cent for tribute," is the origin of the famed shibboleth, although the words were not his. Pinckney did, however, exclaim at one point in the conversations: "No! No! Not a sixpence!")

In a carefully reasoned statement covering the American position, presented by the mission on Jan. 17, 1798, the United States offered to extend to France the same privileges granted to Britain under the terms of Jay's Treaty. At the same time it demanded reparations for the spoliation of American shipping. After a lengthy delay, Talleyrand countered with an offensive proposal to treat with Gerry alone, characterizing the other ministers as unfriendly to France. This latest indignity exhausted the Americans' patience. Outraged by Talleyrand's conduct, Marshall and Pinckney left Paris—the former sailing to a hero's welcome in the United States, the latter going to the south of France with an ailing daughter—but Gerry, naively thinking that his presence in the capital would serve to forestall a French declaration of war, remained in Paris but undertook no further negotiations with the French.

President Adams, on March 19, submitted a report to Congress on the unsuccessful negotiations, and two weeks later made public the commission's report. The details of the affair stung the American public to a high degree of indignation, and there was clamor—especially among the Federalists—for an immediate declaration of war. Congress took steps in the summer of 1798 to respond to the French effrontery—authorizing the capture of French armed ships, terminating all commercial dealings with France, abrogating the alliance of 1778, and fortifying the nation's defenses. George Washington was summoned from retirement to take command of the American Army.

Martial fervor swept the young republic, and events might have proceeded toward a tragic climax had not Adams courageously resisted public opinion and labored for a peaceful settlement. To the utter chagrin of his own party, which was reaping rich political dividends from the anti-French sentiment, and in the realization that any conciliatory gesture toward France undoubtedly would injure his political future, the Federalist president announced the appointment of William Vans Murray as minister to France. The way had been prepared for renewed contacts when Talleyrand let it be known that he would look favorably on the assignment of a new envoy. Under Federalist promptings, however, Adams agreed to entrust the venture to a three-man commission, including Murray. The Americans were received with courtesy by Napoleon, and the ensuing negotiations culminated in the Treaty of Mortefontaine (or Convention of 1800), which formally released the United States from the alliance and ameliorated strained feelings on both sides of the Atlantic. Thus ended the so-called Quasi War between the two countries.

Military action during the two-year dispute was confined to naval engagements, with both sides preying on each other's shipping. The small but able United States Navy captured about 85 armed vessels, mostly French privateers operating in Caribbean waters.

	Y	y				y		y	

A. C. SYLVESTER, CAMBRIDGE, ENGLAND

The development of the letter Y is illustrated in the chart above, beginning with the early North Semitic letter. The evolution of the majuscule (capital) is shown at top; that of the minuscule (lowercase) at bottom.

Y, wī, the 25th letter of the English alphabet, in origin identical with *u*, *v*, and *w*, notwithstanding the great variety of sounds that it designates. Other symbols have also been used for the different values of *y*, notably *ȝ*, a variety of *g* (as in Old English *ȝeaf*, "he gave"; *ȝeoc*, "yoke"). In early printed texts *y* was taken as the closest type form for the Old English thorn, *þ* (*th*), which led to the mistaken notion that *ye* is an archaic form of *the*, and to a corresponding mispronunciation. *Y* may also go altogether unwritten, as in *union*.

One explanation for the English name of the letter is that, since *Y* looks like *u* (in the form *V*) set over *i*, the name *ui* or *wi* was invented to describe this apparent construction. The modern French name, *i grec* (Greek *i*), indicates clearly the actual source of the symbol, at least in its vocalic value.

After the Greek *v* had become *ū*, it was borrowed into Latin (in the 1st century B.C.) as distinct from *u*, in words of Greek origin (*Pyrrhus*) and even in words, Greek or not, in which *i* was proper (*hystoria*, *Ytalia*). So in English we have *y* both in genuine Greek words and in words supposed to be such (*rhyme*, O.E. *rim*).

In the Greek alphabet, *v* stands after *τ*, and before the added signs *φ*, *χ*, *ψ*, which stamps it as a novelty. Moreover, it had properly a vocalic value only; English consonantal *y* is of different origin, namely the palatal *g* or consonantal *i*; since the symbol *ȝ* (pronounced like *y* in *you*) survived in northern England and Scotland longer than in the south, it came in Scottish practice of the 16th century to be confused with *z*. Hence the form *Menzies* (pronounced *Mengies*), although a spelling pronunciation has survived in some cases (*MacKenzie*).

The *y* of Old English which arises from *u* by unilaut, as in *mȳs*, the plural of *mus*, is now written *i* (*mice*). In such an archaism as *yclept*; the *y* is nothing more than the prefix *ȝe-* (German *ge-*) substituted for the *t-* into which it had passed in Middle English (*icleped*, O.E. *gecleopod*).

As an abbreviation, *y* is used in algebra for the second unknown quantity; and more generally for *y*-shaped objects (*Y-cartilage*; *Y-branch*).

YAAN, yā'an', municipality and special district, China, in west-central Szechwan Province. Situated on the Chengtu-Kunming railroad, 60 miles east of Kangting, Yaan is an important tea-processing and automobile-repair center and is noted for its exports of bamboo shoots, foodstuffs, and animal products. Pop. (1967) 55,200.

YABLONOVY MOUNTAINS, yi-blā-nō'vi (formerly called YABLONOVY MOUNTAINS), mountain range, USSR, in eastern Siberia, extending from southwest to northeast, approximately 625 miles long, 12½ to 75 miles wide, and 5,250 to 5,900 feet high. From the city of Kyakhta, in the Buryat Autonomous SSR, on the border of the Mongolian People's Republic, the mountains run east of Lake Baikal along the eastern border of the Buryat ASSR and the western border of Chita Oblast into Amur Oblast, where they merge into other ranges at the Olekma River. The Yablonovy Mountains are the watershed between rivers flowing into the Arctic and Pacific oceans. Except for the rocky highest peaks, the range is covered with forests. Tungsten, molybdenum, and gold are mined.

ELLSWORTH RAYMOND

YACHTS AND YACHTING, yōts, yōt'ing. In the broadest sense, a yacht is any boat, vessel, or ship privately owned and used for pleasure, although the term is only occasionally applied to small undecked sail, motor, and rowing boats. Yachts may range from such small open craft to sumptuous sailing and diesel-engine-powered vessels 200 feet long; since World War II, however, pleasure vessels more than 100 feet in length have been few. The term includes partly decked sail- or power-boats for day sailing and racing; cabin cruisers propelled by sail, power, or both (the last called auxiliaries); and big sea-going vessels. Yachting, likewise, is a term that covers a multitude of activities: afternoon sailing, small-boat racing, leisurely coastwise cruising in sail or power craft, round-the-world voyages, international racing, entertaining aboard luxury vessels, and many more.

History. The once common conception of yachting as exclusively a millionaire's sport was never wholly accurate, at least in American history. Even colonial records list boats used for pleasure by men of modest means. Now, with the increase of income and leisure time among more people, yachting has become a popular pastime, enjoyed by millions in a wide range of financial brackets. It is widespread in the United States and in many other countries, particularly Canada, Britain, western Europe, Brazil, Argentina, Australia, and New Zealand.

The word *yacht* came into English through Dutch *yaght* (now *jacht*) from the earlier Low German *jacht* or *jachtschiff*, meaning literally a hunting ship, used by pirates (or against them). The sport of yachting, however, may be traced back to Egyptian, Greek, and Roman days, when

royalty maintained "pleasure barges." Charles II introduced the pastime into England in 1660 when he returned from exile in Holland. The earliest recorded yacht club (1720) was the Water Club of Cork Harbor, Ireland.

In America, an engraving of New York Harbor dated 1717 identifies "Col. Morris' yacht *Fancy*," and history indicates that many craft were privately owned for pleasure at that time. Early short-lived yacht clubs were the Knickerbocker Boat Club in New York City in 1811 and the Boston Yacht Club in 1835. The oldest surviving organization in the United States is the New York Yacht Club, founded in 1844, which held its first cruise that year and its first regatta in 1845; except for interruptions by war, these events have been held annually ever since. Today there are probably 1,500 clubs in the United States devoted to the sport of yachting, many of them on inland rivers and artificial lakes where yachting was never thought of until the 1930's and 1940's. Some are elaborate and expensive, but many are simple and unpretentious, serving the small-boat owner of modest means. In many harbors, marinas provide berthing facilities where sailboats and powerboats can be moored safely and conveniently in limited areas.

DESIGN AND OPERATION

Design and Construction.—Early yachts were modeled after commercial, naval, and fishing vessels of their time and place and built by the same men, often to lines taken from small models whittled and scraped to shape from a block of pine. The modern practice of designing a yacht on paper according to scientific principles began,

in the United States, after the Civil War. Now naval architects draft and calculate each line and element of a yacht before building is begun.

Concurrent with scientific designing came the gradual evolution of distinct yacht types, although the influence of commercial types is still evident. There is no single "yacht type," but there are many types of yachts, each designed for the waters where it is to be sailed, the use to which it will be put, and the particular requirements of the owner.

All yacht design is a compromise. Features that make for high speed, for instance, generally sacrifice some seaworthiness, comfort, and ease of handling. The ideal boat for a shorthanded cruise around the world would make a poor showing in a race, and one suitable for coastwise cruising differs from both a deepwater craft and a racer. Strict economy in first cost, maintenance, and operation is incompatible with the full attainment of other desirable qualities. A boat appropriate for shallow, protected waters may perform badly in a rough ocean or large lake, and vice versa. This principle is true of power-driven as well as sailing boats. A boat buyer should decide when, where, and how he is going to use his boat, then get one that fits the job.

For centuries, standard yacht construction was of the wooden-frame-and-plank type. Iron and steel were used for large yachts in the later 19th century and are used now in some 30- and 40-footers. In these sizes iron and steel compete with aluminum, which is used increasingly for smaller craft. Special aluminum alloys must be employed to prevent saltwater corrosion. To some extent, plywood has replaced conventional wooden plank

PETER HACKAY/MORRMEYER

Family day-boating and cruising on rivers, lakes, and bays are enjoyed by many in a variety of power boats.

ing for small craft in recent decades. The greatest growth since the mid-1940's has been in the building of molded, fiber-glass-reinforced plastic boats. This is now very popular in small craft and increasingly so in those up to about 40 feet long, sail and power. It has advantages in maintenance and is economically practical for building large numbers of identical small boats. In large craft built in very small numbers, prices become virtually prohibitive due to the high cost of making the molds.

Yacht building in the United States, traditionally carried on in hundreds of small plants around the country, currently shows a trend toward fewer and larger concerns. While once virtually every pleasure craft was individually designed and built, today nearly all small craft and many sail and power yachts up to 50 feet long and more are either stock or standardized in design and build for purely economic reasons.

Power Yachts. Steam power was applied to yachts during the latter part of the 19th century, and in the early 1900's many wealthy men owned luxurious steam yachts, used more often for entertaining and ostentatious display than for satisfying any real taste for the sea. The naphtha launch had a brief vogue in the late 19th century, and early in the 20th century the internal combustion gasoline engine began to be fitted to pleasure craft, both as the prime motive power and as auxiliary power in sailing yachts. The refinement and increasing economy of gasoline engines rapidly brought power yachting within the reach of those of modest means.

A major factor in more recent years has been the outboard motor, a self-contained power plant hung on the stern of a boat. Originally a low-powered "substitute for a pair of oars," outboards are now built in units of as much as 100 horsepower.

See also **MOTORBOATS.**

Yacht Speeds. The speed of yachts and, indeed, of all vessels involves the type of hull. There are two types: displacement hulls and planing hulls. The displacement hull moves through the water, pushing aside a weight of water equal to its own. Two factors, skin friction and wave making, limit the speed. The practical limit of speed of a vessel of this type is called the speed-length ratio, the speed being relative to the square root of the effective waterline length. A 36-foot sloop sailing at 7.8 knots¹, a 100-foot fishing schooner making 13 knots, and a 900-foot ocean liner smashing along at 39 knots are all maintaining a speed-length ratio of 1.3 to 1. For such vessels to increase these speeds even by small fractions takes an enormous increase of power. The sailing vessel would be likely to lose masts or blow out sails in the attempt, and the steamer would use up a disproportionate amount of fuel for every fraction of a knot of increase.

The speed-length ratio of 1.3 to 1 is considered a good performance. Some vessels never exceed a 1 to 1 ratio; a few, designed primarily for speed, may reach 1.4 to 1 or possibly 1.5 to 1 under ideal conditions. To exceed that, however, a hull is no longer acting entirely as a displacement hull, but is to some extent "planing."

Records made by sailing yachts with displacement hulls include the transatlantic record of 12 days 4 hours 1 minute from Sandy Hook lightship to The Lizard on England's south coast, an average of 10.3 knots, set in 1905 by the 134-foot waterline schooner *Atlantic*; the 30-mile triangular race record of 2 hours 47 minutes 59 seconds, at 10.7 knots (fastest leg, 13.3 knots) by the 84-foot waterline sloop *Yankee* in a 1930 America's Cup trial; and the record for the 635-mile Newport-Bermuda race of 70 hours 11 minutes 37

¹ 1 knot = 1 nautical mile (approximately 1 1/4 statute miles) per hour.

seconds, a 9-knot average, by the 51-foot water-line yawl *Bolero* in 1958.

Planing (and semiplaning) boats exceed these speeds by lifting partly out of the water and skipping along the surface. Ability to do this depends on the design of the boat's bottom, lightness of weight in proportion to size and power, and application of high power (motor or wind). The water must be fairly smooth, since a boat planing in a heavy sea is likely to bounce and turn over or break up.

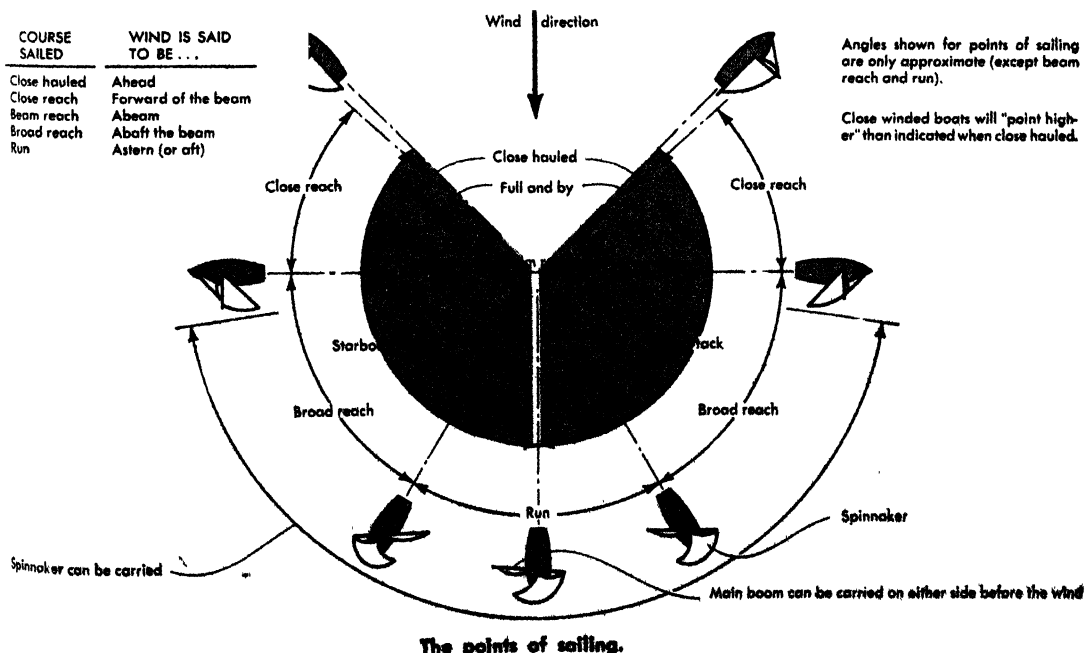

Motorboats of the hydroplane type, riding on literally a few square inches of their bottoms, have made speeds as high as 240 miles per hour, using engines of more than 3,000 horsepower in hulls only about 30 feet long. Sailboats cannot draw on any such power, since winds strong enough to produce it would blow away their sails and rigging; but they can exceed the speed-length ratio. Traditional planing sailboats are the inland lakes scows—light, wide, flat hulls with big sail plans—which in very strong winds have been clocked at around 25 mph. More conventional but specialized small planing boats like 14-foot dinghies, Flying Dutchmen, 5-0-5 Class boats, and numerous others also reach high speeds when conditions are just right. Catamarans, modern versions of a 1,000-year-old type of craft floating on two long, slim, parallel hulls, although not strictly planing boats, are free from some of the limitations of wave making and friction affecting more conventional hulls, and can sail very fast. A 40-foot seagoing catamaran is reported to have been timed at 28 mph.

Principles of Sailing. Sailing, with its infinite variety of boats and conditions, is an art that may take a lifetime to perfect, but its basic principles are so simple that a 10-year-old can learn in a few hours to sail a small, simple boat safely and adequately in good weather and protected water. Forward motion of a sailboat is induced by wind blowing on the sails, which must be properly trimmed to utilize it. Trimming is done with a rope called a sheet, which pulls the sail toward the middle of the boat.

Basic features of a sailboat.

In *running*—with the wind coming from dead astern or nearly so—sails are slacked out nearly at right angles to the keel (axis) of the boat. In *reaching*—with the wind coming over the quarter (broad reach) or broadside (beam reach) or from not more than 40° forward of the beam (close reach)—the sails are trimmed in just enough so that they do not shake and spill wind, but no closer.

T. M. GREEN

This double-ended cruising sailboat is designed for long voyages and living aboard at the expense of speed.

Beating to windward is harder. A boat can sail to a point in the exact direction from which the wind is blowing by making a series of zigzag *tacks*. With sails trimmed as near amidships as they can be, a smart boat will sail on a course about 45° off the wind. Very close-winded boats under ideal conditions sometimes sail within 40° ; many will not sail closer than 50° or 55° . To reach a point to the north when the wind is blowing from the north, one should steer northeast for a while with flat-trimmed sails, then come about and steer northwest, continuing thus on alternating tacks until one reaches the destination.

To change from one tack to the other, one swings the boat into the wind's eye and past it until sails are full on the other tack. Jibing, or changing tacks by steering away from the wind until one brings it on the other side of the sail, can be dangerous and requires expert steering and sail handling.

What keeps a boat from simply blowing sideways before the wind is her lateral plane. This is the area of the hull below water as viewed in profile; it is usually increased by adding to the hull proper a keel extending below it, or a centerboard, or both. The centerboard, a flat plate of wood or metal, is pulled up inside the hull when the boat is running before the wind or is at anchor. It may be partly lowered for reaching and is fully lowered when working to windward. All boats, when beating, make some leeway (sideslip), but good ones make only a few degrees from the course steered.

The afterpart of the lateral plane includes the rudder with which the boat is steered. This is pivoted at its forward end and controlled by a tiller (straight stick) or a steering wheel and

gear inside the boat. As the tiller end is pulled to the right, the afterpart of the rudder swings left, and the bow turns left (to port). For a right or starboard turn, the tiller end is pulled left, and the afterpart of the rudder swings right.

Ballast (heavy weight in the keel or inside the hull) acts as a pendulum to keep the boat upright against the heeling (tipping) force of the wind. When the wind blows hard enough to heel the boat dangerously, sails are reduced in area by reefing, or some sails may be dropped altogether. In very hard winds, small, strong storm sails are substituted for the working sails. In very light airs, many boats set large, lightweight balloon-type sails. A boat when sailing is stopped by steering her directly into the wind (*luffing*) or by slacking sheets until the sails shake and spill the wind.

RACING (SAIL)

Racing Classes. There are hundreds of sailboat racing classes of all sorts and sizes. Some are local and involve only half a dozen to a few score boats; others are national and international and number up to several thousand. They may be divided broadly into three groups: one-design classes, rating classes, and handicap classes.

In *one-design* classes, boats are as nearly alike in hull, rig, and equipment as they can be made. Racing success depends on the skill of the skipper and crew in maintaining the boat in top condition and sailing her well.

Rating classes compete without time allowance. The boats are not identical but must not exceed a certain figure when measured under one of a variety of mathematical rating formulas. These formulas take into consideration from one to a score of factors affecting a boat's speed, such as length, sail area, weight, type of rig, beam, draft, ballast, wetted surface, and certain structural features. One of the simplest is the old Seawanhaka Rule: "Length plus Square Root of Sail Area, divided by 2, equals Rating." Under this, a boat 30 feet long with 400 feet of sail would rate 25 feet. Most rules have grown extremely complicated (one fills a 20-page booklet) mainly to prevent designers from producing undesirable "freak" boats that rate low but may be unseaworthy, overly fast but expensive to build, or subject to breakdown in fresh winds. Two widely used rules developed early in the 20th century are the Universal Rule, used principally in the United States, and the International Rule developed in Europe. Universal Rule ratings are expressed in feet, as a 25-foot rating, also called Class Q; international ratings are expressed in meters, as 12-Meter and 6-Meter. The International Rule has largely superseded the Universal Rule even in the United States.

Handicap racing is practiced where dissimilar boats race together in one group, as in a club regatta, and in virtually all long-distance and ocean races. Here each boat's measurements are taken and her rating calculated under a rule such as described before. For each tenth of a foot of rating, a standard time allowance table gives the second-per-mile handicap that the boat would receive from an arbitrarily selected scratch boat. This figure is multiplied by the length in miles of the course to be sailed, to produce the time allowance that is deducted from the actual elapsed time of each boat in the race. The result is the corrected time, on which most prizes are awarded. For cruising-boat races, the measurement rules

AMERICA'S CUP RACES

Year	Winner	Loser	Races
1851	America (U.S.)	Royal Yacht Squadron (England)	1-0
1870	Magic (U.S.)	Cambria (England)	1-0
1871	Columbia (U.S.)	Livonia (England)	4-1
1876	Madeline (U.S.)	Countess of Dufferin (Canada)	2-0
1881	Mischief (U.S.)	Atlanta (Canada)	2-0
1885	Puritan (U.S.)	Genesta (England)	2-0
1886	Mayflower (U.S.)	Galatea (England)	2-0
1887	Volunteer (U.S.)	Thistle (Scotland)	2-0
1893	Vigilant (U.S.)	Valkyrie II (England)	3-0
1895	Defender (U.S.)	Valkyrie III (England)	3-0
1899	Columbia (U.S.)	Shamrock (England)	3-0
1901	Columbia (U.S.)	Shamrock II (England)	3-0
1903	Reliance (U.S.)	Shamrock III (England)	3-0
1920	Resolute (U.S.)	Shamrock IV (England)	3-2
1930	Enterprise (U.S.)	Shamrock V (England)	4-0
1934	Rainbow (U.S.)	Endeavour (England)	4-2
1937	Ranger (U.S.)	Endeavour II (England)	4-0
1958	Columbia (U.S.)	Sceptre (England)	4-0
1962	Weatherly (U.S.)	Gretel (Australia)	4-1
1964	Constellation (U.S.)	Sovereign (England)	4-0
1967	Intrepid (U.S.)	Dame Pattie (Australia)	4-0
1970	Intrepid (U.S.)	Gretel II (Australia)	4-1
1974	Courageous (U.S.)	Southern Cross (Austral.)	4-0
1977	Courageous (U.S.)	Australia (Australia)	4-0
1980	Freedom (U.S.)	Australia (Australia)	4-1
1983	Australia II (Australia)	Liberty (U.S.)	4-3
1987	Stars & Stripes (U.S.)	Kookaburra III (Australia)	4-0
	Stars & Stripes (U.S.)	New Zealand (N. Zealand)	2-0

most commonly used are those of the Cruising Club of America, the British Royal Ocean Racing Club, and the Storm Trysail Club (United States). The rules are intended to give each boat, as far as possible, an even chance of victory when many boats of different size and design are racing. The control of freak boats, by penalizing them with high ratings, is a secondary but still important factor.

Racing Rules. The rules that govern fair sail-boat racing and specify which boats have the right of way in various tactical situations at close quarters are virtually standardized everywhere. Originally based on the International Rules of the Road at Sea for commercial sailing vessels, they have become much more detailed and elaborate. The Rules of the Road are designed to keep ships at a safe distance from each other, while the racing rules apply to boats that are necessarily sailing close together. Factors in determining the right of way include which boat is on port and which on starboard tack (a boat is on starboard tack when the wind comes over her starboard or right side and the sail is therefore on the port or left side, and vice versa); which boat is overtaking another; which is to windward and which to leeward; and the presence or absence of obstructions such as shoals, buoys, and other boats. Variations and definitions clarify these rules according to circumstances. In general, port-tack, overtaking, and windward boats are required to keep clear, and room has to be given at obstructions and course markers.

Since no umpire or referee follows the ordinary sailing race to enforce rules, enforcement depends on the voluntary withdrawal from the race of a boat that has broken a rule, or a protest may be made against her by the skipper of another boat. Both sides are heard and a decision made by the race committee after the contest.

International Yacht Racing. The America's Cup has been for over a century the top prize of international yacht racing. The schooner yacht *America*, built in New York City in 1851 for a group of members of the New York Yacht Club,

The U. S. 12-meter yacht *Freedom* takes the lead over the challenger *Australia* in the 1980 America's Cup races.

was 101 feet long, a typical American schooner of the fast seaworthy type then used by New York pilots. She was sailed to England, where she won a trophy of the Royal Yacht Squadron called the Hundred-Guinea Cup in a race around the Isle of Wight against 17 British yachts. During the Civil War the *America* was used by the Confederates as a blockade runner and then was captured and used as a Federal naval dispatch boat. Later she became a yacht again and in 1921 was presented to the United States Naval Academy at Annapolis, Md., where she was broken up in 1946.

The Hundred-Guinea Cup became known as the America's Cup after it was decided to the New York Yacht Club by the yacht's original owners in 1857 to be an international challenge trophy. A clause in the deed of gift, inserted to ensure that only really seaworthy yachts would compete for the cup, required a challenger to cross the ocean under sail on her own bottom. The cup has always been raced for by yachts of the largest active racing classes in point of size. Since 1870 attempts to take the America's Cup were made by Canada, Scotland, Australia, and England. The New York Yacht Club defended it successfully until 1983.

In 1958, after a 21-year lapse of races, the longest in the history of the trophy, the deed of gift was altered, permitting somewhat smaller yachts to race and dropping the requirement of sailing across the ocean.

Three U.S. yachts twice defended the cup successfully: *Columbia* (1899, 1901), *Intrepid* (1967, 1970), and *Courageous* (1974, 1977). The British lost challenges in 1958 and 1974. After losing its first six challenges Australia, represented by *Australia II*, defeated the U.S. *Liberty* in 1983. The *Stars & Stripes*, sponsored by the San Diego Yacht Club, regained the cup in 1987.

In the following year New Zealand issued an unorthodox challenge to the United States for another America's Cup race three years sooner than was usual. The San Diego Yacht Club accepted the challenge. The challenger's yacht was the *New Zealand*, a 132-foot monohull; the U.S. entry was the *Stars & Stripes*, a 60-foot multihull catamaran. The U.S. yacht easily won the first two of the best of three scheduled races in September 1988. New Zealand went to court, charging that San Diego's use of the catamaran created a mismatch and was illegal inasmuch as a multihull is much faster than a monohull. After moving through lower courts, the case was finally disposed of in favor of the San Diego club, which was awarded the trophy by the New York court of appeals.

The America's Cup is only one of many international sailing events. International competition in the Olympic Games, which began in 1900, has fostered keen rivalry. Five classes of boats have been raced: 5.5-Meter sloops, keelboats of open design with three-man crews; Dragons, one-design keelboats with three-man crews; Stars, keelboats with two-man crews; Flying Dutchmen, planing centerboard boats with two-man crews; and Finn Monotypes, one-man centerboarders.

Besides the America's Cup, there are many challenge trophies, originating in various nations, which are raced for internationally, such as the Seawanhaka Cup, British-American Cup, Scandinavian Gold Cup, One-Ton Cup, and Coppa d'Italia. For many years those named were competed for in the 6-Meter Class, but this has been largely superseded by the 5.5-Meter, which is a smaller and less costly type of sloop.

A number of large one-design classes also hold international championships. Some are limited to one or two countries where these classes are popular; others are truly worldwide in distribution, like the Star Class, Snipe Class (16-foot centerboard sloops), Flying Dutchman, and others. These are generally annual or biennial events.

Ocean Racing. Although the first transatlantic yacht race was sailed in December 1866, this branch of the sport began to attain its present popularity early in the 20th century among owners of relatively small but seaworthy cruising yachts. Among the best-known regularly scheduled ocean races are the one from the east coast of the United States to Bermuda and the one from the west coast to Honolulu, both of which date from 1906; the British Fastnet race from southern England to the Irish coast and back; and races from Sydney, Australia, to Hobart, Tasmania; Buenos Aires, Argentina, to Rio de Janeiro, Brazil; San Diego, Calif., to Acapulco, Mexico; Los Angeles, Calif., to Ensenada, Mexico; and Victoria, British Columbia, offshore to Swiftsure Bank and return. The Southern Ocean Racing Circuit includes five winter contests in waters between Florida and the Bahamas.

Ocean racing led to the development of yachts that are slightly less speedy than the ex-

treme racing types but offer excellent accommodations and seaworthiness in all weathers. In World War II many of these ocean-racing yachts were used by the U.S. Coast Guard on submarine patrol along the coast. Skippers and navigators and most of the crews on ocean-racing yachts usually are amateurs.

WILLIAM H. TAYLOR

Former Managing Editor of "Yachting"

Yafa, ya'fā (Ar. Yafī'), a landlocked tribal area and tribal confederation in the Western Aden Protectorate (WAP), Arabian Peninsula, bounded on the north by Yemen and elsewhere by other WAP sultanates: Audhali ('Awdhālī) on the east; Fadhli (Fadlī), south and southeast; Amiri, west. The terrain is elevated, between 1,000 and 2,000 feet near the coast, rising gradually from about 3,000 feet to peaks over 8,000 feet farther inland. Much of the country is tangled mountains and ravines. It is hot in summer and, in the mountains, cold in winter. In the higher areas rainfall is about 20 inches a year. The people are Arabic-speaking Muslims.

The chief grain crops are sorghums, wheat, and barley. Dates grow up to an elevation of 4,000 feet, and a variety of fruits and vegetables are raised. In the western part of Lower Yafa coffee is an important crop.

The area's industry and communications are primitive. Camels and donkeys are the chief means of transportation.

Yafa is divided into two sultanates: Lower Yafa (capital Al Qara; al-Qārah), and Upper Yafa (capital Mahjaba; Mahjabah). There are also minor sheikhdoms within Upper Yafa. The law practiced in Yafa is a combination of Islamic and tribal law. Lower Yafa is a member of the Federation of Arab Amirs of the South (formed in 1959).

Previously under Yemen, the Yafa, like other Aden Protectorate peoples, were gradually brought under British sway following the conquest (1839) of the town of Aden. A British protectorate was established over Lower Yafa in 1895, and a treaty signed with Upper Yafa in 1903. Traditionally the British did not supervise internal protectorate affairs, but in the 1930's they began to bind the various small states by "advisory treaties" (Lower Yafa, 1944–1945) providing for a resident adviser, whose advice to the ruler was obligatory. Yafa tribes have considerable importance in southern Arabia because they furnish mercenaries and the dynasties of several other important south Arabian sultanates (Lahj, or Lahj; Mukalla) are of Yafa origin.

Yahi Indians. See YANA INDIANS.

YAHOO, yā'hōō, in the 4th voyage of Jonathan Swift's famous satire *Gulliver's Travels* (1726), the name given to a race of brutes, described as having human forms and degraded natures. They were subject to the Houyhnhnms, or horses endowed with human reason. Hence, the term has come to be applied to a rough, low, boorish, or uneducated person. See also GULLIVER'S TRAVELS.

YAJUR VEDA. See VEDIC LITERATURE.

YAK, yāk, an animal (*Bos grunniens*) of the Bovidae family, distributed in the high bleak plateaus and mountains of Central Asia. It is found in Tibet, Kansu (northwest China), and the Chang Chenmo Valley of Ladakh (eastern Kashmir). It ranges from the lower valleys to 20,000-foot levels, feeding on coarse grasses. The wild yak moves in winter from the snow-covered slopes to the valleys.

Wild yaks are black, shaggy animals about the size of common oxen, with a shoulder height of about 5 feet 2 inches. They have enormously long hair which continues down the tail, giving it a bushy appearance. Their horns come straight across and then curve upward, and may measure 40 inches from tip to tip. Domestic yaks are smaller (shoulder height about 4 feet 3 inches), consisting of half-breeds—male wild yaks crossed with female Zebus (Indian humped cattle)—mainly black and white in color. The yak is exceptionally well adapted to endurance of cold and shows superb stamina, which makes it an excellent animal for carrying people and other burdens. Its numbers are decreasing, although it once was as abundant as the American bison. Old bulls wander about in twos or threes, but females and calves herd together for protection.

A. W. Ambler from National Audubon Society
Yak (*Bos grunniens*).

The domesticated forms, although used principally for transportation, are valued also for their meat. This is of excellent quality, and calf meat is especially tasty. The cows provide quantities of rich milk. The Tibetans also extract good yields of butter, which they use to flavor their tea or to burn in religious shrines. The long hair of the yak is made into ropes, while hides with hair are used as coverings for tents. The tails are sometimes dyed bright red

and sold as flyflappers in the cities of India.

ALFRED NOVAK,
Chairman, Division of Science and Mathematics,
Stephens College, Columbia, Mo.

YAKIMA, yāk'-ə-mə, city, Washington, Yakima County seat, on the Yakima River, 100 miles southeast of Seattle. It is a commercial and industrial center for the irrigated Yakima Valley, which produces fruit (especially apples), grain, vegetables, sugar beets, hops, and livestock. The city manufactures lumber, flour, cider, clay products, and clothing, and has many packing plants. There is an airport.

Yakima Valley College is situated here, and the city has a museum and an art gallery. Other cultural institutions are the Yakima Valley Regional Library, the Little Theatre, and the Yakima Symphony. Points of interest in the vicinity include the Yakima Indian Reservation, historic Fort Simcoe (a relic of the Yakima Indian War of 1855-1858), the White Pass ski area, and fishing resorts. Fruit orchards in bloom attract visitors each spring. The United States Army Firing Center is an important training center for both desert and mountain warfare.

Yakima was founded in 1885. The first settlement was made in 1861 four miles to the southeast, but the town was moved to the present site when the Northern Pacific Railway built a station there. Until 1918 it was called North Yakima. The original settlement is now Union Gap. Yakima adopted a city manager-council government in 1960. Population: 54,827.

ELINOR EVANS.

YAKIMA INDIANS (from Indian *yaqimá*, run-away), an important division of the Shahaptian language family, formerly living on both sides of the Columbia River and along the northern branches of the Yakima and Wenatchee rivers in the State of Washington. Meriwether Lewis and William Clark, who encountered them in 1806, called them Cutsahnim and estimated their number at 1,200. In 1855 they ceded their homelands to the United States, accepting settlement upon a reservation in Washington, where they were to be established as a confederacy of 14 tribes under the leadership of Chief Kamaia-kan. The unruly impatience of white miners and settlers upset these plans, and the unnecessary and tragic Yakima War of 1855-1858 resulted. Eventually, some of the original tribes withdrew from settlement as an outgrowth of the bitterness of the war.

The term "Yakima" is used today to include loosely many tribes in the general area, particularly those living on the Yakima Reservation in Washington; it is therefore impossible to estimate tribal membership accurately. The culture of the whole group is much like that of all of the Shahaptian folk. Approximately 4,442 "Yakima" reside on the reservation in Washington.

FREDERICK J. DOCKSTADER.

YAKIMA RIVER, river, Washington, rising in the Cascade Range near Snoqualmie Pass. After a southeastward course of about 200 miles, it flows into the Columbia River at Richland, about 6 miles west of Pasco and Kennewick and 10 miles above the confluence of the Snake River. The Yakima flows through a coal-mining region, and its irrigated valley and the valleys

of its numerous short tributaries are among the most fertile in the state. The chief tributary is the Naches River, which joins the Yakima at the city of Yakima, the major city on its banks.

YAKOVLEV, yä'kaf-lyäf, **Aleksandr Sergeyevich**, Soviet aircraft designer: b. Moscow, USSR, March 19, 1906. The son of a machinist, he was interested in aeronautics, particularly the building of aircraft engines, from early youth. While he was attending the Zhukovsky Air Force Engineering Academy in Moscow, from which he graduated in 1931, his attention turned to aircraft design. In 1936 his airplane won the "Round the USSR Tour"; this design proved so successful that it was used extensively for private flying clubs, and Yakovlev soon became recognized as one of the leading and most versatile Russian aircraft designers. He was commissioned by the government to build for the Air Ministry a high speed executive transport, known as the Yak-2, which was later redesigned as a dive bomber. In 1940 he was appointed deputy commissar (later deputy minister) of the aviation industry; he served in this capacity through World War II and after, until 1948. During the war he designed light bombers, fighters, and training airplanes. His later designs range from supersonic medium bombers and twin jet fighters to tandem rotor helicopters and a series of training and light general-purpose aircraft.

ELIZABETH B. BROWN.

YAKUB KHAN, yä-kōōb'khān', **Mohammed** (MUHAMMAD YA'QŪB KHĀN), amir of Afghanistan: b. 1849; d. Dehra Dun, India, Nov. 15, 1923. He was the eldest son of Amir Shir Ali. Disappointed because his father favored a younger son, Abdullah Jan, he revolted in 1870 and captured the city of Herat, but under British pressure was reconciled with Shir Ali and made governor of Herat. However, in 1873, after naming Abdullah heir apparent, Shir Ali seized Yakub Khan and imprisoned him. During his confinement (1874-1878), Afghanistan again became the focal point of Anglo-Russian rivalry in Central Asia. The amir's dealings with the Russians provoked a British ultimatum and, finally, a military advance (November 1878). The Russians declined to assist Shir Ali, who fled, and Yakub Khan was named regent, the heir apparent having died in August 1878.

Upon the death of Shir Ali in February 1879, Yakub became amir and carried on the fight (Second Afghan War) against the British until peace was restored in May. A British mission, specified in the treaty, went to Kabul, but in September the entire mission staff was killed by Afghan troops. Thereupon the British reentered Afghanistan and took Kabul. On Oct. 12, 1879, Yakub Khan abdicated and shortly afterward was sent to India, where he died.

NORMAN ITZKOWITZ.

YAKUT AUTONOMOUS SOVIET SOCIALIST REPUBLIC, yä-kōōt', administrative division, USSR, in the Russian SFSR. A vast territory of 1,188,400 square miles, situated in northeastern Siberia, it has impenetrable forests and an exceptionally severe climate, and is very sparsely populated. It is bounded on the west by Krasnoyarsk Krai; on the north by the Arctic Ocean; on the east by Magadan Oblast and Khabarovsk Krai; on the south by Amur, Chita, and Irkutsk oblasts.

The republic is drained by the Olenek, Lena, Yana, Indigirka, and Kolyma rivers, all debouching into the Arctic Ocean. The central part is formed by the valleys of the Lena and its tributaries, the Vilyui and Aldan; the western tableland is crossed by low mountain ranges; in the east, high mountains form the Verkhoyansk and Stanovoi ranges. The city of Verkhoyansk has the world's greatest fluctuation in temperature, the recorded minimum being -94°F . and the recorded maximum 93°F .; the average January temperature is -57°F . and the July average 60°F . The northern tundra, vast marshy plains overgrown with mosses and lichens, is followed farther south by the "shrubby tundra," which in turn passes into dense conifer forests—the Siberian taiga.

The Yakuts, a Turkic branch of the Ural-Altaic peoples, constitute about 56 percent of the population; Russians, 36 percent; Tungus, Lamuts, Yukagirs, and Chukchi make up the rest. The Yakuts engage in hunting and trapping furbearing animals, in fishing, and in reindeer, cattle, and horse breeding. They obtain valuable mammoth ivory from frozen carcasses found in surprising quantities. Russian settlers introduced agriculture in the 19th century along the Lena and its tributaries, where stretches of fertile alluvial soil are frequent. Agriculture is collectivized, using modern techniques. The crops are barley, spring rye, wheat, potatoes, turnips, and cabbage. The principal towns are Yakutsk (q.v.), which is the capital, Verkhoyansk, Vilyuisk, Olekminsk, Tommot, and Sredne-Kolymsk.

The Yakut Republic has no railroads; Skovorodino, 500 miles south of Yakutsk by road or sledge tracks, is the nearest station on the Trans-Siberian Railroad. River transportation is possible for a short time in the summer; northbound shipping on the Lena makes connection with the northern sea route of the Arctic Ocean. Most important are the airlines connecting Yakutsk with Irkutsk (on the Trans-Siberian Railroad), Vilyuisk, Verkhoyansk, and Tiksi Bay on the Arctic Ocean, from where the air route continues to Archangel and Moscow. Gold is mined extensively in the Lena Basin; silver- and lead-bearing ores are worked; other mineral deposits, including rich reserves of coal, are hardly touched. Pop. (1961) 527,000.

NICOLAI RABENECK.

YAKUTAT INDIANS, yäk'a-tāt, a subdivision of the Tlingit tribe of North American Indians, inhabiting an area around Yakutat Bay, Alaska. They are particularly known for their fine basketry. Their culture is wholly that of the other Tlingit tribes. See also TLINGIT.

FREDERICK J. DOCKSTADER.

YAKUTSK, yä-kōōtsk', city, USSR, capital of the Yakut Autonomous SSR (q.v.), a port on the Lena River, 3,000 miles east-northeast of Moscow. It is an important trading center for the republic's main exports: gold, ivory, and furs. The city's few industries (brickworks, sawmills, tanneries, ship repair yards) have only local significance. Most of the houses of the predominantly Russian population are one-story log cabins. Yakutsk has several technical schools, a teachers college, and a branch of the Academy of Sciences of the USSR. Pop. (1959) 74,000.

NICOLAI RABENECK.

YALA, yà-là, province, Thailand, on the Malay Peninsula. It is bounded by the provinces of Songkhla to the northwest, Pattani to the north, and Narathiwat to the east and by the Federation of Malaya to the south and southwest. The area is 1,895 square miles. The population is predominantly Malay in culture and language and Islamic in religion.

The Pattani River, which rises in hills in the south that reach an elevation of 5,000 feet, flows through the center of the province. The provincial capital, the town of Yala, lies on the river and on the railroad line that runs from Songkhla to northeastern Malaya. A partly paved road runs north-south through the province to Malaya. The principal export products are tin, tungsten, and rubber. Chinese capital and labor are dominant in the mining and rubber industries.

Yala was one of seven small vassal states created when the Malay sultanate of Pattani, a vassal state of Thailand, was split up by the Thai after a rebellion broke out there in 1790. It was incorporated into the kingdom proper as a province after the reorganization of the Thai provincial government in the 1890's. Pop. (1980) 265,276.

WALTER F. VELLA.

YALE, yal, Elihu, English philanthropist: b. Boston, Mass., April 5, 1649; d. London, England, July 8, 1721. His father, David Yale, was an early settler in New Haven, Conn., but soon moved to Boston and then returned to England, where Elihu was educated. Entering the employ of the East India Company, Elihu went to Madras in 1672 and became governor of the company's fort there in 1687. In the meantime he had married a widow of means and, through lucrative investments and independent trading, amassed a considerable fortune. He was removed from office in 1692 and returned to England in 1699. He became famous as a collector of paintings and art objects and as a public benefactor. In 1717 he was elected a fellow of the Royal Society.

Yale never revisited New England, but he was persuaded to contribute substantial support to the new Collegiate School which had been founded at Branford, Conn., and then moved to New Haven. His gifts of salable materials, books, and other items were estimated at some £1,162. In his will he also left a legacy to the college, but it was held invalid in a series of court actions. The largest gift, in 1718, followed a suggestion from Cotton Mather that "if what is forming at New Haven might wear the name of Yale College, it would be better than a name of sons and daughters." After receiving this gift the trustees of the college wrote Yale of having "done our School the Honour of naming it with your Illustrious Name & have called it Yale-Colledge." This was done at the school's first commencement (1718) in the building financed by Yale. After his death his body was returned for burial in the parish churchyard at Wrexham, Denbighshire, in north Wales, near the family country estate where he had spent most of his time during his years of retirement.

CLAUDE A. EGGERTSEN

Professor of Education, University of Michigan.

YALE, Linus, American locksmith and manufacturer: b. Salisbury, N.Y., April 4, 1821; d. New

York, Dec. 25, 1868. The son of a distinguished inventor and locksmith also named Linus Yale, he began work on bank locks about 1851. In a field marked by sharp competition, Yale produced three types of bank locks operated by keys designed to prevent picking and to allow changes in the combination. About 1862 he brought out the Yale Monitor bank lock, which marks the transition to the dial-operated combination lock.

Beginning about 1860, Yale gave much attention to smaller locks for general use. In 1861 and 1865 he took out patents for a cylinder lock with pin tumblers. The pin lock had first appeared in ancient Egypt, and much interest was taken in this principle in both England and the United States after 1790. Yale's lock excelled because it combined simplicity of construction with great variation in the possible combinations. It was also well adapted to quantity production. Because his factory at Shelburne Falls, Mass., was fully occupied with work on bank locks, he planned to build a new works, and in 1868 the Yale Lock Manufacturing Company at Stamford, Conn., was formed to produce the cylinder locks. After Yale's death that year, a partner, Henry Robinson Towne, carried on the business.

ABBOTT PAYSON USHER

Author of "A History of Mechanical Inventions"

YALE UNIVERSITY, the third-oldest institution of higher learning in the United States, located in New Haven, Conn. It was founded in 1701 in Branford, Conn., as the Collegiate School. Classes were held initially in nearby Killingworth, Milford, and Saybrook before the institution moved in 1716 to New Haven and was renamed Yale College in recognition of the gifts of its first benefactor, Elihu Yale (q.v.). The first New Haven building, Yale College, was built in 1717; Connecticut Hall, constructed in 1750-1752, still stands. In addition to the college, the university has a graduate school and professional schools of art and architecture, divinity, drama, forestry, law, management, medicine, music, and nursing.

The Yale student body comes from every state

Harkness Memorial Tower stands out over the rooftops of the Jonathan Edwards College yard at Yale.

Philip D. Gendreau

P. Guerrero

The David S. Ingalls Rink, designed by a distinguished Yale alumnus, Eero Saarinen, was opened in 1958. It is used for team games and recreational skating.

of the United States and more than 75 other countries. Average enrollment is approximately 8,000, almost equally divided between graduate and undergraduate students. Over 30 different kinds of degrees are awarded annually. Women were first admitted for undergraduate study in 1969.

Growth and Facilities.—Although the Connecticut General Assembly did not authorize the name Yale University until 1887, President Ezra Stiles' "Plan of the University," which foreshadowed the organization of universities throughout the United States, was inaugurated as early as 1810, when the Medical Institution of Yale College was chartered. The Divinity School was begun with the creation of a separate department of theology in 1822, and the Law School affiliated in 1824. The art gallery, erected in 1832, was the first connected with a college to be built in the United States. It was followed by what is now known as the School of Art and Architecture, founded in 1865, and by the Peabody Museum of Natural History in the same year.

Meanwhile, an important step was taken in 1847 with the establishment of courses in graduate instruction through the Department of Philosophy and Arts. The gifts of Joseph E. Sheffield in 1861 consolidated this work into the Sheffield Scientific School, which became the leading scientific and engineering institution in the United States; its work is now carried on through Yale College and the Graduate School.

In 1861 the degree of doctor of philosophy was

awarded for the first time in the United States by Yale. The Graduate School was organized under its own dean in 1892, and women were admitted to it for the first time during the same year. The School of Music was established in 1894, the Forestry School in 1900, and the School of Nursing in 1923. The School of Engineering, which had formerly been a part of the Sheffield Scientific School, was established separately in 1932; and the Department of Drama, originally set up in 1924, became the School of Drama in 1955. Yale's new Art Gallery was completed in 1953. It was designed by Louis Kahn, who also designed the Yale Center for British Art, donated by Paul Mellon and inaugurated in 1977. The School of Organization and Management was established in 1974 and opened in 1975.

The Institute of Far Eastern Languages and the Bureau of Highway Traffic are also organized within the university. Summer work in Norfolk, Conn., is provided by the School of Art and Architecture and the School of Music. A summer language institute and other special programs are conducted by the Office of Teacher Training in the Graduate School.

After freshman year (during which housing is provided in the dormitories on the Old Campus), the students in Yale College live in 12 residential units known as colleges: Berkeley, Branford, Calhoun, Davenport, Timothy Dwight, Jonathan Edwards, Morse, Pierson, Saybrook, Siliman, Ezra Stiles, and Trumbull. Each has its own library, dining hall, kitchen, common rooms, squash courts, and accommodations for about 250 students. A master and his family live in each college, and students can associate with 20 or more members of the faculty who are appointed as fellows. The plan was initially made possible by gifts from Edward S. Harkness (B.A., 1897) and later supported by Paul Mellon (B.A., 1929).

Among the important benefactions of John W. Sterling (B.A., 1864) is the Sterling Memorial Library. Within it and the 42 subsidiary departments of the University Library are housed 4.5 million volumes, one of the largest collections in the world. It began with 40 books given by the founding fathers and had expanded to nearly 2,000 by 1718. Undergraduate literary and debating societies added volumes, a tradition perpetuated by friends and graduates.

The Church of Christ in Yale University, founded in 1757, is interdenominational, although Congregational in origin. The Chapel of St. Thomas More was constructed in 1938 for Roman Catholic students, and the Hillel Foundation was organized in 1942 to conduct Jewish services. There are also Episcopalians, Presbyterian, Methodist, Congregational, and Lutheran chaplains on the campus. Dwight Hall, the Young Men's Christian Association center at Yale, provides leadership and facilities for religious and social service programs.

A mile and a half west of the campus are 720 acres devoted to athletics and a golf course. The Yale Bowl, constructed in 1914, has a seating capacity of 70,900. Adjacent to the campus is Payne Whitney Gymnasium, a gift from Whitney's wife and his children, Mrs. Charles Shipman Payson and John Hay Whitney (B.A., 1926). The David S. Ingalls Rink, designed by Eero Saarinen (B.F.A., 1934), is used by the university hockey teams and for recreational skating.

Administration.—The final authority of the university is the Corporation, a body of 19 trustees

onsisting of the president of the university, the governor and lieutenant governor of Connecticut ex officio, 10 fellows ("successors of the original trustees") serving until the traditional faculty retirement age of 68, and 6 alumni fellows elected every year by the graduates to serve for 6 years. The alumni trustees were substituted in 1872 for inactive senior state senators who had been placed in the Corporation in return for financial assistance from the state in the late 18th century.

Yale presidents (rectors until 1745) have been: Abraham Pierson (1701-1707), Samuel Andrew (1707-1719), Timothy Cutler (1719-1722), Elisha Williams (1725-1739), Thomas Clap (1740-1766), Naphtali Daggett (1766-1777), Ezra Stiles (1778-1795), Timothy Dwight (1795-1817), Jeremiah Day (1817-1846), Theodore Dwight Woolsey (1846-1871), Noah Porter (1871-1886), Timothy Dwight (1886-1899), Arthur Twining Hadley (1899-1921), James Rowland Angell (1921-1937), Charles Seymour (1937-1950), Alfred Whitney Griswold (1950-1963), Kingman Brewster, Jr. (1963-1977), A. Bartlett Giamatti (1978-1986), and Benno C. Schmidt, Jr. (1986-).

Curriculum and Student Activities.—Yale has adhered to the classical tradition of liberal arts education since its beginning. In the mid-19th century it introduced some of the new sciences and social studies; at the turn of the century it adopted the elective system and in due course the principle of "distribution and concentration." Since World War II a series of honors programs, the Scholars of the House Program for exceptionally able students, and the Directed Studies Program for qualified underclassmen (followed by the standard or interdepartmental major) have attracted special attention to a curriculum which is designed for either the generalist or the specialist, while maintaining the integrity of the basic liberal disciplines.

Student extracurricular activities are an important part of university life. The *Yale Literary Magazine* (established 1836) is believed to be the oldest college monthly, and the *Yale Daily News* (founded 1878) claims to be the oldest college daily. Among the many other activities are the Yale Glee Club, the Yale Band, the student radio station WYBC, the Political Union, and the Debating Association. Yale has seven junior fraternities and seven senior societies.

The university's alma mater song is *Bright College Years*, and several of its popular football songs were composed by Cole Porter (B.A., 1913). The mascot is a bulldog; the college color is blue. Students are known as Elis (after Elihu Yale).

Alumni.—Graduates of Yale have long taken an active interest in the affairs of the university. In 1890 they formed the first alumni fund in the United States and in 1906 organized the Alumni Board to keep graduates informed of Yale activities. The University Council, established in 1948, initiated a system of visiting committees that advise and assist in academic matters.

Yale's original charter called for the training of youth "for Public employment, both in Church and Civil State." In U.S. presidential cabinets since 1789, 8-12% of the members have been drawn from Yale. The college has produced several justices of the Supreme Court, and many of its graduates have become presidents or founders of other colleges and universities.

REUBEN A. HOLDEN,
Secretary, Yale University.

YALTA, yál'tə, city, USSR, on the southeast coast of the Crimean Peninsula, in the Crimean Oblast of the Ukrainian SSR. The city lies in a natural amphitheater between the Crimean Mountains and the Black Sea. It has a subtropical climate and, with its many sanatoriums and rest homes, is the largest summer and winter resort in the Crimea. Many of the sanatoriums are former czarist villas. Local industries are small and consist mainly of food processing.

Yalta was the site of ancient settlements as long ago as the 1st century A.D. During the 14th and 15th centuries it was a colony of Genoa and then of Turkey from 1475 to 1783, when it was annexed by Russia. During the second half of the 19th century, Yalta grew from a village of 1,000 inhabitants to a large resort, where the czar himself had palaces. In 1945 the Yalta Conference of Joseph Stalin, Winston Churchill, and Franklin D. Roosevelt was held in a suburb. Population: (1979 census) 80,000.

ELLSWORTH RAYMOND,
New York University

YALU RIVER, yá'lōō' (Korean AMNOK-KANG), river, Asia, forming the border between Korea and China along its entire course of 500 miles. Its drainage area is over 24,250 square miles (about 12,300 square miles of it on the Chinese side). The Yalu originates in the Changpai Mountains and flows swiftly into Korea Bay. It is navigable for larger vessels for about 15 miles in the lower reaches, but only for small craft in the other sections. The river borders the Manchurian provinces of Kirin and Liaoning on the Chinese side, and North Pyongan, Chagang, and Yanggang in North Korea. Important cities at its mouth are Antung (Chinese) and Sinuiju (Korean); both of these have sawmills and other wood-processing industries to utilize the timber that is floated downstream.

The Yalu River has a hydroelectric power potential estimated at 1.5 million kilowatts, comparable to that of the Sungari River in Manchuria. A considerable portion of the billion rubles of Soviet aid to North Korea in 1954-1956 was expended for the restoration of the Supung hydroelectric power plant on the Yalu, after its near-destruction by United Nations planes in June 1952. Modernization in 1958 reportedly brought the installed capacity up to 700,000 kilowatts. North Korean surveys indicate that there are five locations on the Yalu that could sustain power plants as large as the Supung station.

The crucial importance of hydroelectric power provided to Manchurian industry by the Yalu may have been one of the reasons why the Chinese Communists entered the Korean War when United Nations troops reached the river. However, construction of electric power facilities in Manchuria since 1953 may have lessened the importance of the Supung installations to China.

RICHARD SORICH,
East Asian Institute, Columbia University.

YALUNG RIVER, yá'lōōng', river, China, in western Szechwan. A canyon stream about 800 miles long, it rises in the Bayan Kara Mountains in southeastern Tsinghai (Chinghai) Province and

empties into the Yangtze River on the border of Yunnan, west of Hweili.

YAM, yām, the common name for plants of the genus *Dioscorea* of the family Dioscoreaceae (called the yam family), or for their tubers. In the United States certain varieties of sweet potato are incorrectly called yams. True yams, of which about 600 species are known, are found throughout tropical and warm temperate regions. Four species are native to the United States.

Yams are herbaceous vines whose stems twine consistently to the right or left, depending on the species. They have usually heart-shaped, prominently veined leaves; clustered small green, white, or yellow flowers; and three-angled capsules containing winged flat seeds. Yams are among the most important tropical root crops, some kinds being baked, boiled, or fried, some used for soup, and some dried and ground into meal.

The most commonly cultivated species, *D. alata*, is native to Southeast Asia but is grown in all warm countries. Its many varieties differ greatly in shape, color, and size of tubers. The skin is brown or black; the flesh, white to purple or red. The tubers may grow 8 feet long and weigh 130 pounds. Certain varieties of *D. bulbifera*, the air potato, are grown for their subterranean tubers; other varieties, for the aerial tubers borne at the base of the leaf stalks. Some poisonous or ill-flavored yams may be eaten after treatment to make them palatable. One of the most poisonous, *D. hispida*, is a chief famine food in Southeast Asia. Tubers of some species of yams contain compounds (botogenin, diosgenin) convertible into cortisone (q.v.). The cinnamon vine, *D. batatas*, so called from the odor of its flowers, is also cultivated as a garden ornamental.

See also SWEET POTATO.

JOHN W. THIERET.

YAMA, yām'a, in the Vedas or ancient sacred literature of the Hindus, the god of the dead, over whom he presides with the help of a twin sister, Yami. They are looked upon as having been the first human pair, and one of the Vedic hymns tells how Yami lured Yama to cohabit for the purpose of founding the human race. At a later period, the epics show Yama not only as presiding over departed spirits, but as judging them and assigning them to heaven, hell, or additional reincarnations. Still later, the Purāṇas (scriptures dealing with legend and history) picture him dwelling in an underworld city called Yamapura, where in the presence of many wives he sits on a throne of judgment while his messengers, called Yamadūtas, bring in the souls of the dead and carry them off to their assigned punishment or reward.

In literature and art Yama is usually represented as green in complexion, clothed in red, riding a black buffalo, armed with a mace and noose, and accompanied by fierce, four-eyed dogs. In shape he resembles a plump yaksha or tree spirit, and sometimes leaves rise over his head and shoulders. His dark green color, his big belly, his buffalo, his dogs, his association with trees, and above all his incestuous marriage indicate that he is either a pre-Aryan deity or an Aryan one who quickly adopted the ways and looks of the conquered people's gods. His transformation from an Aryan Adam to the judge of the dead in Dravidian form shows, perhaps, an Aryan fear that the conquered would revenge themselves

in the next life, if not in this one.

RODERICK MARSHALL,
Professor of English, Brooklyn College of the City
University of New York.

YAMAGATA, yā-mā-gā-tā, PRINCE Artomo, Japanese army commander and statesman: b. Hagi, Japan, April 22, 1838; d. Odawara, Feb. 1, 1922. He was the person chiefly responsible for reorganizing the Japanese Army on European models and for making the military class the most powerful faction in the government. Born into a lower order of the Choshu warrior clan, Yamagata was educated under the nationalist Shoin Yoshida and was prominent in the overthrow of the shogunate in 1867. The new imperial government sent him to Europe to study the military systems of France and Germany, and as minister of war in 1873 he built a new conscript army which defeated the Satsuma rebels four years later. In 1878 he became chief of the newly created general staff and in 1884 was made a count.

While minister of home affairs in control of the police, Yamagata supported the constitution of 1889, which kept power in the hands of the ruling oligarchy. Chiefly in order to prevent civilian interference in military affairs, he continued to take a leading part in politics for the next decade, serving as premier (1889-1891 and 1898-1900) and minister of justice (1892-1895). He originated the practice of having only active officers appointed as war and navy ministers, whose resignation could topple any cabinet that opposed them. As spokesman for the military faction in the government, he was the principal and finally victorious opponent of Prince Hirobumi Ito (q.v.) from 1890 to 1901. He proved a skillful strategist during the Sino-Japanese War (1894-1895), after which he became a marquis, and during the war with Russia he was again chief of the general staff (1904). After 1901 he retired from active politics, although he continued to exert some control over the political scene, becoming president of the privy council in 1905 and remaining Japan's most influential elder statesman until his death. He was created prince in 1907.

YAMAGATA, prefecture, Japan, in the northern part of Honshu Island. Its area is 3,601 square miles. It was created from the former Province of Uzen and a district of Ugo Province. The city of Yamagata (q.v.) is the capital.

The greater part of the prefecture is mountainous. The basic economic activity is agriculture, based on the cultivation of rice, of which Yamagata is a surplus producer. The center of rice production is the Shonai coastal plain facing the Sea of Japan. Sericulture and fruit growing are also important, and Yamagata is the cherry-producing center of Japan. Some petroleum, lignite, and natural gas deposits are exploited, and there are small fishing and forestry industries.

Near the city of Yamagata is the Mount Zao resort area, one of Japan's most popular skiing grounds. There are also many hot spring spas in the same area and in the city of Kaminoyama and its vicinity. Pop. (1983 est.) 1,256,000.

GEORGE H. KAKIUCHI
Assistant Professor of Geography, University of
Washington.

YAMAGATA, city, Japan, capital of Yamagata Prefecture, in northern Honshu, on the Mogami

River, 39 miles by rail west of Sendai and 180 miles north-northeast of Tokyo. Formerly called Mogami, it was an important castle town from 1356 and served as the residence of various daimyo during the Tokugawa period (1603-1867). It became a city in 1881. The inner town still reflects the influences of the feudal period in its place names and street patterns.

Yamagata's economic activity centers about agriculture and manufacturing. Traditional household industries produce such items as iron kettles, Japanese umbrellas, Buddhist altars, and Paulownia papers. Modern industry, which developed after World War II, includes the manufacture of sewing machines and electrometallurgical products, the latter oriented toward the export market. The city is also the hub of commerce and transportation for the adjacent agricultural area, and a resort and sporting center (see YAMAGATA, prefecture). Yamagata University is situated here, and among the city's notable buildings are an ancient Shinto shrine, Hachiman, and a castle last occupied by the Mizuno family (1845 to 1868). Pop. (1960) 188,597.

GEORGE H. KAKIUCHI.

YAMAGUCHI, yā-mā-gōō-chē, prefecture, Japan, at the southwestern end of Honshu, the main island of Japan. The area is 2,348 square miles. The capital is the city of Yamaguchi (q.v.). The prefecture was created from the former provinces of Suwo and Nagato. In early Japanese history, this area functioned as a corridor of trade and communication between Korea and China and the main area of Japan. Yamaguchi produced many able statesmen and military leaders who were active in the struggles of the Meiji Restoration (1868) and during the Meiji period that followed. A few of these notable personalities were Hirobumi Ito, Aritomo Yamagata, Takayoshi Kido, and Taro Katsura (qq.v.), and Masujiro Omura.

Although manufacturing and mining are important in the prefecture, they are of recent origin; the traditional agriculture and fisheries were more important until the first quarter of the 20th century. Most of the level land is found on the narrow coastal plains, and rice is the main crop. Fishing is still one of the main industries, and Yamaguchi Prefecture ranks fifth in Japan in this respect, the port city of Shimonoseki (q.v.) being the center of the industry. Bofu (Hofu) and its coastal vicinity are known for salt production by evaporation, and the prefecture accounts for about 10 percent of Japan's production. Mining of coal, manganese, copper, and limestone is important, principally coal, the main fields being located near Ube (q.v.).

The manufacturing zone of Yamaguchi should be considered as an extension of the North Kyushu (Kita-Kyushu) industrial region. Shimonoseki and its vicinity have shipbuilding, metal, and chemical industries, and process fishery products; the Ube-Onoda district has chemical and ceramic factories; Bofu and its environs manufacture chemical fibers; the Tokuyama-Kudamatsu-Hikari district has primary metal, machinery, and chemical industries; and Iwakuni specializes in textiles. Pop. (1960) 1,602,207.

GEORGE H. KAKIUCHI.

YAMAGUCHI, city, Japan, capital of Yamaguchi Prefecture, in the extreme southwestern part of Honshu Island, on the Fushino River, 35 miles by

rail northeast of Shimonoseki. From the 14th century Yamaguchi was the seat of the Ouchi family, whose interest in foreign trade made the town one of the early centers of Western influence. A great number of scholars and court nobles who wanted to escape the disorders at Kyoto, then the imperial capital, sought the hospitality of the Ouchi and came to reside in Yamaguchi. Thus, by the 16th century, the town was a flourishing cultural center. In 1551 it was visited by St. Francis Xavier, the Jesuit missionary, who established a mission (destroyed in the 17th century) and made many converts. From about 1532 the power of the Ouchi family declined, and in 1557 it was dispossessed by the Mori family, which established its seat at Hagi, on the Sea of Japan. As a result, the prosperity and importance of Yamaguchi declined, but it rose to prominence once more when the Mori returned in 1863 and occupied the castle until the Meiji Restoration in 1868. During the struggles preceding the Restoration, Yamaguchi was a base of operations against the Tokugawa shogunate. It became a city in 1929.

Yamaguchi serves primarily as political, cultural, and educational center for the prefecture. Within the city are a monument to St. Francis Xavier and a well-known park, Kameyama, which is laid out on the site of the ancient villa of the Ouchi family. In the park are bronze statues of famous members of the Mori family who took part in the Restoration struggles. Yuda, in the southern part of the city, is a hot spring spa visited mainly by the local population. Pop. (1960) 87,695. See also YAMAGUCHI, prefecture.

GEORGE H. KAKIUCHI.

YAMAL-NENETS NATIONAL OKRUG, administrative division, USSR, located on the Arctic coast of Siberia just east of the Ural Mountains in the far north of Tyumen Oblast, Russian SFSR. The area of 258,800 square miles is a lowland with perpetually frozen soil, consisting of tundra and Arctic forest. The Ob River and its many tributaries are the chief means of transport. Unexploited deposits of iron, lignite, stone, and clay lie in the east Urals, and there are vast peat fields among the many northern lakes. Chief occupations are fishing, reindeer raising, and fur trapping, and the main industry is fish canning. Fish and furs are shipped to other parts of the USSR. The area was formed in 1930, and its capital is Salekhard. Russians and Nentsy (Mongols) predominate in the population. Pop. (1961) 64,000.

ELLSWORTH RAYMOND.

YAMAMOTO, yā-mā-mō-tō, Isoroku, Japanese naval officer: b. Nagaoka, Honshu, Japan, April 4, 1884; d. Solomon Islands, April 18, 1943. Of Samurai descent, he graduated from the Imperial Japanese Naval Academy in 1904 and served aboard the battleship *Nisshin*, at the Battle of Tsushima in 1905. After serving as assistant naval attaché in the United States (1919-1921), he became executive officer and instructor at the Kasumigaura Naval Air Station in 1924. From December 1925 to November 1927 he was naval attaché in the United States and in 1928-1929 commanded the aircraft carrier *Akagi*. He was then head of the Bureau of Naval Aviation of the Naval General Staff and in October 1933 became commander of Carrier Division One. During his various assignments on the Naval General Staff, he made tours of Europe and America to examine naval facilities.

ties. Appointed vice minister of the navy in December 1935 and commander in chief of the First Fleet in August 1938, he was commissioned admiral in November 1940 and was given command of the Combined Fleet in August 1941, a few months before Japan entered World War II.

The Japanese war plan in 1941 was first to seize the rich areas of Southeast Asia and then prepare to meet a United States movement from overseas. This strategy had been successful in the Russo-Japanese War, but Yamamoto claimed that the United States Fleet would have to be destroyed first, before that country's full potential could be brought against Japan. He forced his Pearl Harbor plan on the Naval General Staff, and it was a major success. His campaign against Midway six months later, however, took his country into divergent efforts, and defeat there enabled the United States to seize the initiative in the Solomons in August 1942. Near the end of the desperate struggle for these islands, Yamamoto was shot down in an air ambush over the Shortland Islands. He was granted the title of admiral of the fleet as of the day of his death. Yamamoto was a brilliant, devoted, confident man with a dynamic personality, but complete trust in his genius was one of the major causes of the Japanese defeat.

JOHN D. HAYES

Rear Admiral, United States Navy (Retired)

YAMANASHI, yä-mä-nä-shê, prefecture, Japan, situated inland on central Honshu island, west of Tokyo. The area is 1,724 square miles. It was formerly called Kai Province; its capital is the city of Kofu (q.v.) in the Kofu Basin. The prefecture is composed mostly of mountainous land; the only level areas are found in the Kofu Basin and in some of the small mountain valleys, so that agriculture is very limited. Mount Fuji (see FUJI) and the Akaishi mountain range form the boundary to the south and west, while the Kanto mountain range forms the boundary to the northeast and southeast. Along the northern foothills of Mount Fuji are the beautiful Five Lakes, a well-known recreation and resort area. Mount Fuji, the northern slopes of which lie in Yamanashi Prefecture, annually attracts perhaps 3 million visitors to the city of Fujiyoshida, mainly during July and August.

Among the special agricultural products of the prefecture are fruits (grapes, peaches, cherries, apples) and raw silk. The orchards and vineyards are concentrated on the alluvial fields along the foothills of the Kofu Basin. Sericulture is found mainly on the slopes of the northwestern and western mountains; the prefecture ranks third in Japan in the production of raw silk. Pop. (1983 est.) 816,000.

GEORGE H. KAKIUCHI

YAMASAKI, yä-mä-sä-kê, Minoru, American architect: b. Seattle, Wash., Dec. 1, 1912; d. Detroit, Mich., Feb. 6, 1986. He graduated in architecture from the University of Washington in 1934 and worked in New York City until 1945, when he moved to Detroit to become chief designer for Smith, Hinchman & Grylls. In 1951 the new firm of Leinweber, Yamasaki & Hellmuth (later Yamasaki, Leinweber & Associates; then Minoru Yamasaki & Associates) designed the Lambert Field-St. Louis Municipal Air Terminal, their first important building. The terminal, a spacious and impressive trio of reinforced concrete

groin vaults, won the First Honor Award of the American Institute of Architects (AIA) in 1956. In 1953 a trip around the world had exposed Yamasaki to a wide variety of architectural forms and ornament that had a decisive influence on his work. He concentrated his efforts on "sunlight and shadow, form, ornament, the element of surprise," which he felt were "little explored fields barely understood by today's architects." He asserted in addition: "I am for delight in architecture . . . a joyful quality . . . is essential in building a satisfying environment."

Among numerous other commissions were the U.S. Consulate General in Kobe, Japan (1957); the luxurious and elegant McGregor memorial Community Conference Center at Wayne State University (Detroit, 1958) and the Reynolds Metal Company Building (Southfield, Mich., 1959), both of which won AIA First Honor awards; the immensely popular United States Science Pavilion, a lacelike Gothic structure, at the 1962 Seattle World's Fair; the Civil Air Terminal in Dhahran, Saudi Arabia (1963), another AIA First Honor Award; and the twin towers of the World Trade Center (New York, 1974), in collaboration with Henry Roth & Sons. The twin towers of the World Trade Center in New York City, 110 stories high, are considered by some critics to be absurdly stylized.

HENRY A. MILLON*

*Professor of History of Architecture
Massachusetts Institute of Technology*

YAMASEE INDIANS, yä'mə-sē, a North American Indian tribe of Muskogean stock, closely related to the Hitchiti and once inhabiting Georgia from the Ocmulgee River to the Savannah. The name is perhaps derived from Muskogean *yámasi*, meaning "gentle."

Although first encountered by whites in 1521, the Yamasee remained relatively free from outside influence until the late 17th century, when they moved nearer St. Augustine, Fla., and thus were gradually involved in the English-Spanish rivalry for that region. In 1687 the tribe revolted against the Spaniards and were permitted to settle in the English colony of South Carolina. The resulting Yamasee War of 1715 against the English was an important turning point in relations between Indians and whites in the Southeast. Following their defeat by the English, the Yamasee returned to Florida and remained allies of the Spaniards, but their numbers slowly declined. From a population which, at its height, probably never exceeded 2,000, the tribe seems to have disappeared as an identifiable unit after the Seminole War (1835-1842), although the Oklawaha band of the Seminole Nation may represent its remnants.

A peculiar canoe stroke popular along the Southern coast was called the Yamasee stroke after its inventors.

FREDERICK J. DOCKSTADER

YAMASHITA, yä-mäsh-tä, Tomoyuki, Japanese general: b. Kochi Prefecture, Japan, Nov. 8, 1885; d. near Manila, the Philippines, Feb. 23, 1946. He graduated from the Army Academy in 1906 and rose to the rank of lieutenant general (1937) but held none of the key army posts before World War II. From December 1941 to February 1942 he commanded the Twenty-fifth Army in the swift conquest of Malaya and Singapore, which the British had thought impregnable. Though an able

commander, his success in Malaya owed much to careful planning, in which he had no part, and to mediocre leadership of the numerically superior opposing forces. He was promoted to general (February 1943) but transferred to a remote Manchurian command, reportedly because Prime Minister Tojo Hideki feared his popularity. On Oct. 9, 1944, soon after Tojo's downfall, Yamashita was sent to command the Fourteenth Area Army in the Philippines but was unable to block the American reconquest of the islands. In the first major war crimes trial after World War II, he was charged with command responsibility for permitting his troops to commit wholesale atrocities on Filipino and American civilians and prisoners of war. Though it was only inferentially shown that he knew of the atrocities, an American military commission convicted him of violation of the laws of war, and after unsuccessful appeals to the Philippine and the United States Supreme Court, he was hanged.

ROBERT M. SPAULDING
Oklahoma State University

YAMO USSOUKRO, yá-mōō-sōō-krō', a city in the Ivory Coast, 160 miles (250 km) northwest of Abidjan. A village when President Félix Houphouët-Boigny was born there in 1905, it became the national capital in 1983, but most government business continued to be conducted in Abidjan.

Yamoussoukro's redevelopment began in the mid-1970's. A six-lane highway was constructed from Abidjan, and the town acquired wide boulevards, a presidential palace, a large hotel, and technical colleges. The Roman Catholic Basilica of Our Lady of Peace, built by the president, is larger than St. Peter's in Rome. Population: (1990) about 100,000.

YAMUNA RIVER, yu'mōō-nā, in India, the major right-bank tributary of the Ganges. It rises in the high Himalaya and flows through the Siwalik Hills onto the North Indian Plain, describing a broad arc convex to the southwest along its course of 860 miles (1,375 km). The Yamuna (Jumna), which is nonnavigable, flows past Delhi, Mathura, and Agra before entering the sacred Ganges at the pilgrimage city of Allahabad. Its chief tributary is the Chambal on its right bank. Several important canals flow from headworks on the Yamuna to irrigate extensive tracts on either bank. The long, narrow, fertile region between the Yamuna and the Ganges—called the Doab—is almost entirely irrigated.

JOSEPH E. SCHWARTZBERG, *Editor of*
"A Historical Atlas of South Asia"

YAN FU, yen fō (1854–1921), Chinese naval officer and scholar. He was born on Jan. 8, 1854, in Fujian (Fukien) province. When his father's death interrupted his classical Chinese education he entered the naval academy in Fuzhou, where he learned English and Western sciences before graduating in 1871. After further study at the Greenwich Naval Academy in England, he was dean and later chancellor of the naval academy in Tianjin from 1881 to 1900.

Yan Fu (Yen Fu) sought to apply his newly gained knowledge of the British political system and European liberal thought to the problem of China's weaknesses and subservience to the West under the late Qing (Ch'ing) dynasty. Rejecting the prevalent notion that Western means

(technology) could be made to serve Chinese ends (values), he advocated the adoption of liberal Western principles—but in the interest of enhancing the wealth and power of the state rather than the freedom of the individual; he regarded the Chinese as unready for democratic self-government. He became enormously influential by promoting his ideas through translations of and commentaries on works by T. H. Huxley, J. S. Mill, Adam Smith, Montesquieu, and especially Herbert Spencer.

As a conservative Westernizer, Yan Fu disapproved of the republican revolution of 1911 and gave reluctant support to the reactionary regime of Yuan Shikai (Yüan Shih-k'ai). The carnage of World War I disillusioned him with the West, and he came to believe that the ideas of Confucius and Mencius would best serve the world. Yan Fu died in Fuzhou on Oct. 27, 1921.

YAN Liben, yen lê-bun (died 673), Chinese painter of the early Tang (T'ang) period. The son of a prominent painter and court official, and the brother of another, Yan Liben (Yen Li-pen) was born about 600. He was commissioned by the second Tang emperor, Tai Zong (T'ai Tsung), to paint portraits of officials and scholars, and he became a minister of state himself. His work is best known from the *Scroll of the Emperors* (Museum of Fine Arts, Boston), depicting 13 pre-Tang rulers and their attendants. The first six groups are copies; the last seven, perhaps not. The weight and volume of the figures and the design and interrelationship of the groups are especially noteworthy. The painting's sculptural quality suggests the *Six Horses* (two in the University Museum, Philadelphia), carved in relief on a stone tablet for the emperor's tomb from Yan's designs. Yan was also noted for his interpretations of religious themes and for paintings that showed foreigners.

YANA INDIANS, yā'nā, a tribe of North American Indians belonging to the Hokan linguistic family and at one time inhabiting the upper Sacramento Valley of California from the Pit River to Rock Creek. Yana means "person." The name Nōsi, or Nōzi, formerly applied to this tribe, is obsolete.

The Yana and their kinsmen the Yahi never had a reservation area, but they played a role in California history quite disproportionate to their small population. The California-Oregon trail traversed Yana territory.

Long considered an anthropological mystery, the Yana have become better known, and the belief that they had an Eastern origin has been discarded. One peculiarity of their language is the existence of two forms of speech, one for the men and the other for the women.

The Yana and Yahi population never exceeded 1,500, and they suffered greatly at the hands of the white settlers. In a single night attack, a group of miners surrounded the main Yana village in 1864, massacring all but about 50 individuals. Today few if any Yana survive.

The discovery in 1911 of Ishi, the last surviving Yahi, who lived thereafter at the University of California Museum of Anthropology until he died in 1916, sparked interest in Yahi culture. Famed as the "last Stone Age man," he still knew how to make stone arrowheads and retained many primitive customs.

FREDERICK J. DOCKSTADER*
Author of "Great North American Indians"

YAN'AN, yen'an', a historic town in northern China, in Shaanxi (Shensi) province, 170 miles (270 km) north of the provincial capital, Xi'an (Hsian, Sian). It is situated on the Yan River, surrounded by hills that are honeycombed with caves and terraced for farming. The area is part of a rugged plateau covered with dry, porous, wind-deposit soil known as loess. Yan'an (Yen-an) is a regionally important economic and cultural center, with wool-weaving industries and a university. It is best known, however, as the headquarters of the Chinese Communist Party from 1937 to 1947 during its struggle with both the Japanese and the Nationalist (Kuomintang) Chinese for control of China. Points of interest are the Museum of the Revolution, the caves where Mao Zedong (Mao Tse-tung) and other revolutionary leaders lived during the "Yan'an Period," a pagoda built during the Song (Sung) dynasty (960-1279), caves with Buddhist statues, and a Daoist (Taoist) hermitage.

As early as the 1st century A.D., Yan'an was a frontier military post, and in the 6th century it became a local administrative center. It retained its military defense significance until China's northern frontier was pacified in the late 17th century. The town again rose to prominence with the arrival in 1937 of the Red Eighth Route Army, which had completed its "Long March" from former bases south of the Yangtze River. Until 1947, Yan'an was the headquarters of the Central Committee of the Chinese Communist Party and the focal point of the party's revolutionary activity. It also served as the administrative center of a Communist-controlled region with 1.5 million people. During the Sino-Japanese War (1937-1945) the town was bombed by the Japanese and destroyed; but the Communist leadership stayed on, taking up residence in nearby caves. In the Chinese civil war that followed Japan's defeat, Yan'an was held by Kuomintang forces in 1947-1948. Rebuilt after the establishment of the People's Republic of China in 1949, Yan'an came to be regarded as a national shrine. Population: (1982 census) of the municipality, 250,847.

YANBU, yan'bō, a city on the Red Sea coast of Saudi Arabia, 100 miles (160 km) west of Medina. For centuries it was a way stop for pilgrims visiting the holy cities of Medina and Mecca and was renowned as a center of date production and export. By the 1970's it had a permanent population of about 10,000.

Because of congestion at the major port of Jidda, 200 miles (320 km) to the south, the harbor facilities at Yanbu (Yenbo) were expanded and improved after 1970. At the same time the Saudi government resolved to invest its vast petroleum revenues in projects that would make the country an industrial power. Subsequently a desert tract 5 miles (8 km) south of Yanbu became the site of a huge complex for oil refining, natural-gas processing, petrochemicals manufacturing, and light industries, with pipeline service from the Persian Gulf oil zone, a new industrial port, and a modern urban area that initially accommodated 30,000 people.

YANCEY, yan'sē, William Lowndes (1814-1863), American political leader, who led Alabama into secession. He was born in Ogeechee Falls, Ga., on Aug. 10, 1814. He attended Williams College in Massachusetts and studied law privately in

Greenville, S.C. Initially opposed to nullification (see NULLIFICATION), he became an advocate for states' rights and strict construction of the Constitution after moving to Alabama in 1837. He defended his views as editor of the Cahawba *Southern Democrat* and the Wetumpka *Argus*.

Yancey was elected to the lower house of the Alabama legislature in 1841 and to the state senate in 1843. He resigned in 1846 to practice law but soon was drawn back into politics, opposing the Wilmot Proviso and the Compromise of 1850. After Abraham Lincoln's election in 1860 had prompted secession, Yancey tried and failed to gain European recognition for the Confederacy. He then served in the Confederate Senate. He died in Montgomery, Ala., on July 27, 1863.

YANG, yāng, Chen Ning, Chinese-American physicist; b. Hefei, Anhui province, China, Sept. 22, 1922. He was encouraged to study mathematics and the physical sciences by his father, a prominent teacher of mathematics. After graduate work in China, he was awarded a scholarship for study abroad and in 1945 entered the University of Chicago, where he received his doctorate in physics in 1948. The following year he was named a member of the Institute for Advanced Study at Princeton, N.J., and became a full professor there in 1955. In 1957, Yang shared the Nobel Prize in physics with his friend and colleague Tsung Dao Lee for their joint work in upsetting the principle of conservation of parity as a fundamental law of nuclear physics. They proved theoretically that parity, or "mirror symmetry," might not hold true for certain types of subatomic particles. Their hypothesis was later confirmed by experimental scientists at the National Bureau of Standards, Columbia University, and the University of Chicago. Yang's other contributions were chiefly in the fields of statistical mechanics and symmetry principles.

YANG Zhu, yāng (440-360 B.C.), Chinese philosopher. A representative of Daoism (Taoism), he became widely known mostly through scathing criticisms by Mencius, the Second Sage among the Chinese, who said of him that he "adopts the principle of 'each one for himself,' and would not sacrifice a single hair for the benefit of the whole world."

Very little is known about the life of Yang Zhu (Yang Chu), and except for chapter 7 in the Daoist book *Liezi* (*Lieh-tzu*), bearing the title "Yang Zhu," nothing is left of his teaching. In this brief chapter is set down clearly and candidly a view of life and value as refreshing as it is unorthodox. His critics have called him an egoist, hedonist, pessimist, and fatalist. Far from being a debauchee or a prophet of doom, Yang Zhu wanted to be true to nature and to conduct himself accordingly. For human life, self-preservation constitutes its beginning and happiness its end. To live pleasurably is to live naturally. Imposition of assistance upon others is as bad as infringement. With regard to benefiting the world by sacrificing a hair, Yang Zhu observed, "When nobody would sacrifice a hair, when nobody would try to benefit the world, the world would become orderly." Yang Zhu's philosophy is, in line with that of Daoism, one of letting things alone and "to live and let live."

Y. P. MEI, Author of
"The Ethical and Political
Philosophy of Mo-tse"

YANGCHOW or **YANG-CHOU**, yǎng'jō', municipality, China, in west central Kiangsu Province, on the Grand Canal just north of the Yangtze River, 15 miles north of Chenkiang. It is one of three important urban market centers north of the Yangtze River, along with Nantung and Tai-chow. Yangchow serves as an agricultural market, dealing especially in rice, cotton, corn, wheat, beans, kaoliang (a grain sorghum), and salt. Its rice-trading activities are concentrated in the suburb of Chiangtu (formerly Siennümiao), just northeast of the city, and the salt trade takes place mainly in Shiherhwei to the southwest. Yangchow is also a light-industrial center, with some machine shops. As a commercial and trading center, it flourished during the Sui and T'ang dynasties (590-906 A.D.), when the Grand Canal was used extensively for inland water navigation. At that time, the city was the capital of the Yang Kingdom. Marco Polo, who was honorary governor of the city from 1282 to 1285 A.D., referred to it as Yangiu. It was called Chiangtu from 1912 to 1949, when it became a municipality and assumed its present name. Population: (1982 census) 304,959.

YANGCHÜAN or **YANG-CH'ÜAN**, yǎng'chü-än', municipality, China, in east central Shansi Province, about 55 miles east of Taiyüan, on the Peking Highway and the Taiyuan-Shihchiachuang Railway. It is an important railroad town, in the center of a coal- and iron-ore-mining area, and is closely associated with the 13th century iron-working town of Pingting, a few miles to the south, which it superseded after the construction of the Taiyuan-Shihchiachuang Railway (completed in 1907). Yangchüan is the site of a small blast furnace (original designed capacity 20 tons daily), built by the Paochin Company prior to World War I, which supplies limited amounts of pig iron to the large steel mills in Taiyüan. The city is noted for its metal handicrafts, pottery, and gold and silver ware. A new electric power line was built in the early 1950's between Yangchüan and Taiyüan. Population: (1982 census) 466,563.

BARUCH BOXER

YANGON. See RANGOON

YANGTZE KIANG, yǎng'sē kē-āng' (Chin. CH'ANG KIANG or CH'ANG CHIANG), river, China, the longest and commercially most significant river in the country. It flows for 3,430 miles from the highland area in northeastern Tibet and southwestern Tsinghai Province through the Red Basin of Szechwan Province and across the provinces of Hupei, Hunan, Kiangsi, Anhwei, and Kiangsu, and finally empties into the East China Sea near Shanghai. From its point of origin, the Yangtze drops to 1,000 feet above sea level at Ipin, Szechwan, the head of navigation. This section is called the Kinsha (Chinsha) River. After passing through the Szechwan cities of Luchow, Chungking, and Wanhsien, the river traverses the famous Yangtze Gorges just before Ichang in Hupei (130 feet above sea level), after receiving the Wu River on the right. Ichang, the head of navigation for river vessels, is also the site of one of the projects suggested in the 1959 program for the development of the Yangtze River resources; a huge hydroelectric plant was scheduled for construction on the river at the gorges about 4 miles above Ichang. Another project proposed entails

the diversion of water from the upper portion of the Yangtze to the Yellow River in Tsinghai Province; this scheme, when completed, will provide irrigation water for the northwest and eventually for the Tsaidam and Tarim basins.

Map showing the course of the Yangtze Kiang.

From Ichang to the East China Sea there is an insignificant drop in the altitude of the Yangtze. For the first 800 miles from Ichang, the river drops about $2\frac{1}{2}$ inches per mile. For the last 200 miles, the Yangtze flows virtually at sea level. It is estimated that the mean volume of water discharged at the mouth of the river is 770,000 cubic feet per second, while the sediment deposited at the mouth amounts to about 6,428 million cubic feet annually.

The Yangtze is the major east-west transportation artery for central China. It serves a wide hinterland throughout its basin and is navigable for river steamers of from 5,000 to 10,000 dead-weight-ton capacity as far inland as Hankow. To the east of Ichang it widens considerably, facilitating easy passage at least as far as Kiangling, where the entrance of tributaries quickens the current and often leads to a major flood problem. The Kiangling area is the site of a major flood-control project, which was completed in 1952.

The Yangtze was named for the ancient kingdom of Yang (c. 1000 B.C.), which was located along its present lower course. At one time the river entered the East China Sea at a point further south; this earlier course crossed Tai Lake and Hangchow Bay. Today the Yangtze's navigable portions traverse some of the major economic centers of China, and the region it serves is one of the world's most densely populated areas.

BARUCH BOXER,
Assistant Professor of Geography, Indiana University.

YANKEE, yǎng'kē, originally a nickname for New Englanders, a usage firmly established before the American Revolution. During the Civil War, Southerners applied the word, often in a derogatory sense, to any Northerner or member of the Federal armies. Since the Revolution the British have used the term for all Americans, a custom that became particularly widespread during both world wars when American soldiers, Southerners and Northerners alike, were referred to as Yanks or Yankees.

The etymology of the word is uncertain, but

Yankee is generally believed to be a back-formation of the Dutch *Jan Kees*, a variation of *Jan Kaas* (John Cheese), a long-standing nickname in Germany and Flanders for a Hollander. This appellation was also used by the English to designate a Dutch pirate and, in the colonies, as a term of contempt for all the Dutch. Why the term was transferred from the Dutch to colonists in general is not clear. It is certain, however, that Yanky or Yankee was common enough as a surname or nickname for individuals in British colonial areas during the 18th century.

Some theorists have sought the origin of *Yankee* among the American Indians. A Cherokee term for slave or coward, *eankke*, and an Indian mispronunciation of *English* or the French *Anglais* have been offered as sources. But linguists are skeptical about the existence of *eankke*, and the Indians, having their own names for whites, seldom, if ever, used the terms *English* or *Anglais*. However, *Yankee* may well be connected with a Scots dialect word *yankie*, meaning "sharp" or "clever," as in the phrase "a yankie, good horse." In 19th century America to *yankee* meant to cheat, and, as a noun, *Yankee* has become synonymous with thrift, business acumen, and craftiness.

Such associations stem from the subliterary and folk image of the Yankee storekeeper and peddler. Originally, the sharp Yankee was a comic rural figure, an American development of the Yorkshireman, who plays his tricks or bites in British song and story. His haunt was the country store and tavern where he told his jokes, swapped his goods, and hazed city fellows and slower-thinking townsmen. From this regional start, he became national in range as the frontier opened and he went west to try to sell the backwoodsman things they neither wanted nor needed. Typical of the motifs used in Yankee trickster tales are these two. A deacon checks to see whether his clerk has watered the rum, wetted the tobacco, floured the ginger, and put chicory in the coffee. He then says, "Good lad, now come to your prayers!" A trader sells a horse, saying it has two faults, one of which he will reveal before the deal is closed, one after. The first fault is that the horse is hard to catch; the second, that he is not worth anything once caught.

Sam Hyde, Indian half-breed from Dedham, Mass., is a true folk figure about whom Yankee tales once accumulated. More famous are two journalistic creations of the early 19th century: Sam Slick, the Yankee peddler created by Thomas Chandler Haliburton (1796-1865), and Jack Downing, the cracker-barrel philosopher and common-sense politician created by Seba Smith (1792-1868) and imitated by many others. To most people, however, Benjamin Franklin, who preached his gospel of industry and frugality and wangled his way to fame and fortune, is as Thomas Carlyle called him "the father of all the Yankees."

TRISTRAM P. COFFIN,
University of Pennsylvania; Secretary-Treasurer,
American Folklore Society.

YANKEE DOODLE, yāng'kē dōō'dəl, a popular song of the United States, which for more than two centuries has enjoyed the status of a national air. The origin of the song is uncertain, but most of the legends concerning it place its beginnings toward the middle of the 18th century, during the French-Indian wars. The most common legend concerns Dr. Richard Shuckburg, a physician at-

tached to the British Army at Albany, who composed the song to make fun of the provincial Yankee troops. There is little substantiation for this story, but research has established that the song and many of its verses were probably composed during the 1750's and that it was used in derision of the colonials by the British. From then it became very popular, and by 1767 many versions were current in the American colonies. The first known appearance of the song in print occurred in 1782, when it appeared in James Aird's *A Selection of Scotch, English, Irish, and Foreign Airs*, which was published in Glasgow. The fact that this collection contains several Virginia airs and a Negro jig lends weight to the belief that the tune of *Yankee Doodle* is actually of American origin. Its first known American printing was as part of Benjamin Carr's *Federal Overture*, composed in 1794 and published in Baltimore in 1795.

The use of *Yankee Doodle* as a song to poke fun at the Yankees continued to the early days of the Revolutionary War. It is said that when Col. Hugh Percy's troops marched out of Boston in April 1775, bound for Lexington and Concord, they kept step to the strains of *Yankee Doodle*. At Concord they were routed by the colonial troops, and as they beat a disordered retreat to Boston the Yankees followed them, themselves singing *Yankee Doodle*. From that time the song has been considered an American patriotic air.

JOHN TASKER HOWARD.

YANKEE PENNAMITE WARS. See PENNAMITE WARS.

YANKTON, yāngk'tən, city, South Dakota, seat of Yankton County, 60 miles southwest of Sioux Falls, on the Missouri River. Set in a grain- and cattle-raising area, the city is a railroad and shipping center and has a municipal airport. Machine tools, crates, sheet-metal products, and electronic components are manufactured, and poultry and meat products are processed. Yankton is the site of Mount Marty College (Roman Catholic, women), Yankton College, and the state mental hospital. West of the city, on the Missouri River, is Gavins Point Dam. Lewis and Clark Lake, formed by the dam, is a popular recreation area, below the dam is one of the largest fish hatcheries in the United States. Settled in 1858 and platted in 1859, Yankton was named after the Yankton Indians, who lived in the area. The city was the capital of Dakota Territory from 1861 to 1883. It was incorporated as a town in 1862 and as a city in 1869. Government is by commission and manager. Population: 12,703.

EDA F. LIVINGSTON

YANKTON INDIANS (from Indian *thanke tonwan*, end village), one of the three major divisions of the great Dakota Indian family of North America. With the related Yanktonai Indians (q.v.), they constitute the Middle Dakota group, the other two being the Santee and the Teton. The homeland of the Yankton was apparently around Mille Lacs and Leech lakes in Minnesota, where the explorer Louis Hennepin located them in 1683. See also DAKOTA INDIANS.

FREDERICK J. DOCKSTADER.

YANKTONAI INDIANS, yāngk-tə-nā' (f Indian *thanke tonwana*, little end village), the Yankton Indians (q.v.) one of the three major divisions of the Dakota Indian family of North

America. They are regarded as older than the Yankton, and it was from the Yanktonai that the Assiniboin split in ancient times to form a separate tribe. The ancient homeland of the Yanktonai was a large area north of Mille Lacs Lake, Minn.

FREDERICK J. DOCKSTADER

Author of "Great North American Indians"

YANTAI, yen'ti', a city in northern China, on the north coast of the Shandong (Shan-tung) Peninsula in Shandong province. It is situated on a spacious bay protected by a long promontory and islands. The port of Yantai (Yantai), on the south side of the bay, was built early in the 20th century to handle ocean shipping denied access to the northside port of Zhifu (Chih-fu, Chefoo), which had gradually silted. Zhifu, now a fishing center, lies within the extensive and partly rural Yantai municipality.

Yantai is the processing and distribution point for a major fishing operation and for a local agriculture that is noted for its apples and grapes. The chief manufacturing industry is food processing, which includes flour milling, wine making, brandy distilling, and the canning of fish, fruits, vegetables, and meat. Small-scale engineering produces steel and machinery for the area. Yantai is also a summer resort, with excellent beaches.

The ancient port of Zhifu was opened for foreign trade in 1863. The new port of Yantai that superseded it was itself eclipsed by Qingdao (Ch'ing-tao, Tsingtao), developed downcoast after 1898. Yantai became a municipality in 1933 and emerged as the major city on the north coast of the peninsula by being linked into the Qingdao-Jinan rail line in 1955. Under a plan approved in 1978, an economic and technological development zone was established in Yantai for foreign investors. Population: (1982 census) of the municipality, 384,336.

YAO, you, a Bantu-speaking people of Africa living primarily in southern Malawi and northwestern Mozambique, and to a lesser extent in southern Tanzania. The Yao homeland was in northeastern Mozambique, where they early came into contact with Arab traders from Kilwa, on the coast of Tanganyika (mainland Tanzania). By the 18th century they were active in ivory trade with the coast. Subsequently they spread into Malawi and Tanganyika as traders and slavers.

After their subjugation by the colonial powers in the 1890's and the end of the slave trade, the Yao lived by subsistence agriculture and migratory labor. They also maintained their warlike traditions by enlisting readily for military service. Politically, they have never been organized into a single unit. They live in small villages, some of which recognize a common chief who has ritual as well as political authority. Their system of descent and inheritance is matrilineal. Thus, on marriage a man moves to the village of his wife, where his rights are minimal.

Nominally Muslims, the Yao have vestiges of an ancestor cult, and belief in sorcery is strong. Important rituals include rain ceremonies, initiation ceremonies for boys and girls, and first pregnancy ceremonies for women.

ELIZABETH COLSON, *Author of*

"Tradition and Contract: The Problem of Order"

YAO, yā-ō, a city in Japan, in Osaka prefecture, just east of Osaka. The main part of the city has two religious centers, established in the 15th and 17th centuries, and religious festivals are held annually.

Yao is part of the Osaka industrial area. Traditional industries are the manufacture of cotton textiles and items such as brush and thongs for wooden clogs (*geta*), produced in households or in small factories. Modern manufactures include machinery, chemicals, and metals. Yao also serves the surrounding area as a local market center and is a residential suburb of the nearby city of Osaka.

Yao became a city in 1948 through the consolidation of two towns and three villages. Population: (1985 census) 276,397.

GEORGE H. KAKIUCHI
University of Washington

YAOUNDE, youn-dā', the capital of Cameroon. It is situated in a southern highland area 125 miles (200 km) east of the seaport of Douala. Although secondary to Douala in commercial importance, Yaoundé is a transportation hub and the distribution point for one of Cameroon's most productive agricultural regions. Local manufactures include foodstuffs, beverages, cigarettes, textiles, soap, building materials, and printed matter. Besides being the country's administrative center, Yaoundé is its chief center of learning. It contains the University of Yaoundé, the national library and archives, and numerous specialized schools and research institutes.

Yaoundé was founded by the Germans in 1888 as a base for expanding into the interior of their Kamerun protectorate. In 1922, when most of Kamerun passed to France under the name Cameroun, the French made the city the seat of their administration. Later they completed the rail line from Douala begun by the Germans. Except in 1940-1946, Yaoundé remained the capital during the years of French government and after the country became independent in 1960. Population: (1986) 654,000.

YAP, yap, a federated state of Micronesia in the tropical Caroline Islands of the northwestern Pacific Ocean. It consists of the four islands of the Yap group and numerous smaller ones, notably those of Ulithi and Woleai atolls. The state has a total land area of 46 square miles (119 sq km). The capital is Colonia, on Yap Island.

The Yap group is hilly, with fertile soils supporting a dense growth of palms, crotons, and bamboo as well as varied crops. Copra is the main export; tourism also contributes income. The Yapese are Micronesians who exhibit some Melanesian physical traits and speak Yapese, an Austronesian language. They are noted for their traditional stone money in the form of disks—some huge—with holes in the center. They transported the aragonite stone from Palau, 275 miles (440 km) distant, beginning before the 16th century.

Probably the first Westerner to sight Yap was a Portuguese sea captain in 1526. Afterward the group came successively under the jurisdiction of Spain (1686), Germany (1899), Japan (1920), and the United States (1947). From 1979, Yap was one of the Federated States of Micronesia, which gained sovereignty in free association with the United States in 1986. Population: (1980 census) 8,100.

YAQUI INDIANS, yä'kē, one of the two surviving tribes of the Cahita language family, living in southern Sonora, Mexico.

The name is Indian for "chief river"—that is, the Yaqui River, along which the tribe lives. The most warlike of the Cahita people, they have stoutly resisted encroachment upon their territory and even today maintain a large degree of independence and isolation. In 1906–1907 the Mexican government tried to break this resistance by forcible deportation of large numbers to Yucatán and Tehuantepec; this action and the enrollment of the men into the army resulted in the widespread scattering of the Yaqui throughout Mexico. Two small enclaves also exist in southern Arizona.

Nominally Roman Catholic, the Yaqui combine aboriginal and European religious practices to an extreme degree; their elaborate ceremonial is climaxed during Easter week with the Pascua rites, which are familiar to many travelers in the Southwest. The Yaqui use a variety of masks, costumes, and musical instruments in their dances, which amply demonstrate their inventiveness and talent for music. They are most closely related to the Mayo Indians (q.v.). The exact Yaqui population is not known but was estimated in 1950 as between 15,000 and 20,000 and in 1980 at about 22,000.

FREDERICK J. DOCKSTADER.

YAQUI RIVER, river, Mexico, mainly in the State of Sonora but rising in Chihuahua, where its headstream is named the Papigochic, later the Aros. In Sonora, at the junction with the Bavispe flowing from the north, it becomes the Yaqui proper. Soon after it is met by the Moctezuma, another tributary from the north, and flows thence south-southwest for about 200 miles into the Gulf of California. The river is scarcely navigable because of the rugged mountain country and many canyons. Its basin, including tributaries, covers about 34,000 square miles, of which about 800 are in the United States where tributaries of the Bavispe originate. An official commission is developing the region with irrigation networks fed by three large reservoirs: the Guadalupe on the Papigochic near Ciudad Guerrero; the Angostura on the Bavispe; and the Alvaro Obregón just north of Ciudad Obregón.

I. NICHOLSON.

YAQUINA RIVER, yä-kwē'nə, river, Oregon, rising northwest of Corvallis, in Benton County. It flows 50 miles in a westerly direction past the city of Toledo and empties into Yaquina Bay at Newport.

YAQUT, yä-kōōt' (Ar. YĀQŪT IBN-'ABDULLĀH AL-RŪMĪ), Arab geographer and lexicographer: b. in Byzantine territory, 1179; d. Aleppo, Syria, 1229. He was of Greek parentage, as his surname al-Rūmī indicates. Bought as a slave by a Syrian merchant from Hama, he served for many years as a traveling clerk before he was enfranchised. He then continued his travels as a copyist and seller of manuscripts in Syria, Egypt, Iraq, and Iran. From material that he collected firsthand and culled from books, he started compiling in Mosul, Iraq, around 1222, what turned out to be the most comprehensive geographical dictionary in Arabic, *Mu'jam al-Buldān* (modern ed. by Ferdinand Wüstenfeld, 6 vols., Leipzig 1866–73). In it the names of places are alphabetically ar-

ranged and correctly vocalized, and the geographical data are enriched by historical etymological and scientific material. In addition, Yaqut wrote a dictionary of geographic homonyms, *al-Mushtarak*, and another of learned men, *Mu'jam al-Udabā'* (modern ed. by David S. Margoliouth, 7 vols., Leiden 1907–27).

PHILIP K. HITT.

YARACUY, yä-rä-kwē', state, Venezuela, in the northern part of the country, 2,740 square miles in area, between the Sierra de Aroa on the west and the end of the coastal range on the east. Between the mountains are broad valleys, of which those of the Yaracuy River, from which the state takes its name, and of the Aroa River are notable. Part of the Caribbean coastal plain, with rich vegetation, lies in the north. Except in the mountains, the climate is tropical, and heavy rain falls from June to December. Sugarcane, cacao, corn, rice, and coffee are grown. Mineral resources include copper, iron pyrite, lead, platinum, and coal. San Felipe is the capital. Pop. (1983) 304,963.

YARACUY RIVER, river, Venezuela, in Yaracuy State. Rising north of Urachiche, it flows northeast for about 75 miles to Triste Gulf in the Caribbean Sea, 18 miles west-northwest of Puerto Cabello. To the west is an offshoot of the Andes and to the east the Venezuelan coastal range. In its valley sugarcane, cacao, cotton, tobacco, corn, rice, and fruit are grown. Small craft may navigate the river.

YARD, yärd, a unit of length equal to 3 feet or 36 inches. A square yard contains 9 square feet, and a cubic yard 27 cubic feet. The yard as a unit of measure is derived from early English usage. See also MEASURES AND MEASURING SYSTEMS.

YARMOUTH, yär'məth, town, Massachusetts, in Barnstable County, stretching across the center of Cape Cod, between Barnstable and Dennis. It is a popular summer resort area. Cranberries and vegetables are raised for the market. Yarmouth was incorporated in 1639 and named for Great Yarmouth in England. In the earlier 19th century it was a noted fishing center. Points of interest are the Winslow Crocker house, the John Thacher house (1680), and the Yarmouth Historical Society building. Government is by town meeting. Population: 21,174.

MARTHA U. WHITE.

YARMOUTH, town, Nova Scotia, Canada, seat of Yarmouth County, situated on the Bay of Fundy and the Atlantic Ocean, in the extreme southwest part of the province, opposite the State of Maine and 140 miles southwest of Halifax. It is served by the Canadian National and Canadian Pacific railways and has bus, air, and steamship services, including a car ferry to Bar Harbor, Me. Yarmouth is a cool and healthful resort with scenic drives, surf bathing, boating, fishing, and hunting. It is also a port of entry and the chief commercial and shipping center of Nova Scotia's three western counties; at one time it was the greatest ship-owning port per capita in the world. Fishing and lumbering are major industries, with some manufacturing. Strawberries and Irish moss are also shipped from here. Yarmouth was founded in 1761 by colonists from Sandwich.

Mass. Many of the earlier French settlers banished in 1755 found their way back in 1767. In 1785, following the American Revolution, Loyalists arrived from New York and other United States cities. The town was incorporated in 1890. Population: 7,475.

WALTER J. KONTAK.

YARMOUTH, Great, or YARMOUTH, county borough, England, in Norfolk County, 22 miles east of Norwich. The town is built on a narrow slip of land some three miles long between the North Sea and Breydon Water, formed by the silting up of the mouths of the rivers Yare and Bure and the diversion of their combined waters to the south, where they enter the sea between stout timber piers erected in 1613. The diverted rivers form Yarmouth Harbour, which is connected by bridges with Southtown and other places west and north.

Yarmouth, with its suburb of Gorleston, is a highly popular seaside resort with excellent beaches, piers, theaters, and other provisions for amusement. Its position at the confluence of the Yare, Waveney, and Bure rivers, the three main streams of the Norfolk Broads, makes it an important center for boating and freshwater fishing. Yarmouth has also been noted for its North Sea herring fishery, producing a well-known type of cured herring called "bloaters." The townspeople are employed in a variety of other industries as well, including boatbuilding, brewing, engineering, and food processing.

The first charter was granted by King John in 1200. The old town was originally confined on three sides by high stone walls built in the 14th century, of which the Northwest, Southeast, and Blackfriars towers remain. A result of this restriction was the building of 145 extremely narrow lanes or "Rows," in which the homes of the wealthy burghesses were built. Yarmouth was heavily bombed during World War II, and most of the Rows were destroyed. Bombs also caused the near destruction by fire of the Church of St. Nicholas, founded in 1101, the largest parish church in England. Fortunately the walls remained reasonably intact, and it was possible to rebuild the church after the war. The 14th century Tolhouse, the seat of government in medieval times, was likewise severely damaged and subsequently restored. The Old Merchants' House has been restored and is open to the public as a museum. Population (1961): 52,970.

H. GORDON STOKES.

YARMULKE, yär'mäl-kə, the Yiddish name for the skullcap worn by Orthodox Jewish men at all times. The word is probably derived from Turkish *yagınurluk*, through Slavic *yarmulka*, though some derive it from Medieval Latin *armucella*. The Jewish custom of wearing a head covering developed gradually, and only in the 17th century did religious authorities rule that during prayers one must cover one's head. Thereafter the custom rapidly expanded, and the wearing of a head covering (in the shape of the yarmulke) became an established religious duty. The term "yarmulke" was used in Russia, the Ukraine, and Rumania, while in Poland and to the west the skullcap was called *kapl* or *kapele*.

RAFAEL PATAL.

YARN, yärn, a fiber or fibers spun for use in the manufacture of knitted or woven fabrics by hand

or machine, or for thread used in sewing. Its first development came about accidentally when primitive man observed the natural twining of vines and stems. This principle was first adapted in making cords for fastening crude stone implements to handles or hafts, and for fishnets, snares, and ropes used to carry heavy objects or to lash posts together in building dwellings. In time the principle of twisting was advanced to the manufacture of spun yarn and woven cloth. Wherever prehistoric burials or house sites have been discovered, traces of spinning and weaving have been found, such as the scraps of yarns, textiles, and spindle whorls found in the Neolithic lake dwellings.

Almost all yarn is spun, although at times very long filaments, as in silk and nylon, are unspun or show almost no identifiable twist. The process of spinning that forms yarn may be divided into three parts: (1) drawing out, or arranging the fibers in as nearly parallel a form as possible; (2) twisting to hold the drawn-out fibers in position; and (3) winding. In the simpler forms of hand spinning, still in use in many parts of the world, these three processes are performed separately so that intermittent spinning is the rule. The advance in machines in the late 18th and 19th centuries made it possible to do spinning in one continuous process.

Yarns vary greatly according to the fiber used, the number of twists per inch (varying from 3 to 80), the diameter of the fiber or filament used, and the ply of the yarn (single, double, or multiple). Yarns may be smooth and shiny or rough and dull, or they may be used in combination. A fine smooth shiny yarn, for example, may be spun or plied together with a rough and heavier yarn to give a different effect to the finished cloth. Gold, silver, or some other metallic material, cut into very narrow strips and used either flat and alone or applied with some adhesive to paper (as in China) or to some other substance such as leather (as in medieval Europe), may be wound around a core of some fiber like silk or linen. Different colors of yarn may be plied together, and different fibers may be spun together in the same yarn. Synthetic fibers are frequently spun together with some natural fiber such as cotton or wool.

Yarns are spun in either of two directions: clockwise, known as the Z twist; or counterclockwise, known as the S twist. When yarns are plied (sometimes up to 12 or more strands together), the individual strands or single yarns are generally used partly in S twist and partly in Z twist. In general single-ply yarns are rather soft and somewhat fuzzy and only occasionally are used for the warp (vertical yarns) in a woven fabric. Their most frequent use is for the weft (horizontal yarns), where they do not undergo the constant friction of the beater of the loom. Multiple-ply yarns are stronger and so more useful for the warp of a fabric, but they are equally suitable for use as weft.

In measuring yarn the number or count is based on the relationship of the length of the yarn to a unit of weight. If the metric system is used, the numbering of the yarn is based on the number of meters to one gram of yarn. For example, in a No. 8 yarn there are 8 meters of yarn to 1 gram of weight. In numbering cotton, linen, woollen, and worsted yarns, the English system is generally employed. In this system of counting, standard No. 1 yarns have the follow-

ing number of yards per pound:

Cotton	840 yards
Linen	300 yards
Woolen	256 yards
Worsted	560 yards

Higher numbers represent multiples of these lengths per pound; for example, No. 8 cotton has 6,720 yards per pound. Thus, the higher the number, the finer the yarn. Silk and some of the synthetics such as nylon are measured according to the French system, known as the denier system, which calculates the weight of a unit of length instead of the length of a unit of weight; hence the higher the number, the coarser the yarn. The ply of a yarn is also shown by the number; 8/2 signifies a size 8 yarn 2 plied. Plying of yarns reduces their length, as do dyeing and bleaching. All these factors must be considered when planning a weaving project.

The fibers of which yarns are composed are classified in two main groups: natural, and man-made or synthetic. The best-known natural fibers and yarns are linen, cotton, silk, and wool, although many less commonly used fibers such as alpaca, Angora rabbit, camel's hair, llama, raccoon, and even dog hair may be used in spinning yarns. Man-made fibers and yarns began to be used in the early years of the 20th century and by the middle years of the century had become legion. They include acetate, acrylic, polyester, polyvinyl, rayon, glass, and fibers made from a protein base from such substances as skim milk, seaweed, peanuts, and soybeans. All of these fibers vary according to trade names, although the processes of manufacture are much the same for each basic type. The tensile strength and easy washability of many man-made yarns, even when combined with natural fibers, have made them very popular for both hand and commercial weaving.

JEAN LOPARDO.

YARNELL, yär-nēl', **Harry Ervin**, American naval officer; b. near Independence, Iowa, Oct. 18, 1875; d. Newport, R.I., July 7, 1959. He graduated from the United States Naval Academy in 1897 and served during the Spanish-American War. By World War I he was a captain, during part of it on the staff of Adm. William S. Sims. After receiving aviation training, Yarnell became the first commanding officer of the aircraft carrier *Saratoga* (1927-1928). He was then commissioned rear admiral and served for three years as chief of the Navy's Bureau of Engineering and as naval adviser at the London Disarmament Conference of 1930. From 1931 to 1933 he was commander of aircraft in the Pacific Fleet and for the next three years commandant at Pearl Harbor. As commander in chief of the United States Asiatic Fleet (1936-1939) during the Japanese invasion of China, with only a slender force at his disposal, he displayed courage and diplomacy in maintaining American interests in the face of Japanese truculence and isolationism at home. After the gunboat *Panay* in his command was sunk by Japanese aircraft in the Yangtze River on Dec. 12, 1937, Yarnell gained an apology and indemnity from Japan. He retired with the rank of rear admiral on Nov. 1, 1939, one of the able leaders who prepared the United States Navy for the

great test of World War II.

JOHN D. HAYES.

YAROSLAV I, yū-rū-sláf' (baptismal name **GEORGE**; called **THE WISE**), grand duke of Kiev; b. about 982; d. Kiev, 1054. His father, Vladimir the Great (see **VLADIMIR**), made him vice regent of Novgorod, where Yaroslav attempted to set himself up as an independent ruler in 1014-1015. On Vladimir's death in the latter year, Yaroslav became involved with his half brother Sviatopolk the Accursed in a contest for the Kievan throne. Although Kiev itself was briefly occupied (1017-1018) by Sviatopolk's ally Boleslav (Boleslas) I of Poland, the war ended in a victory for Yaroslav, who assumed the throne in 1019. He next had to cope with several other brothers, especially Mstislav of Tmutorokan and Chernigov. After Mstislav won the Battle of Listven (1024), the two brothers divided their spheres of influence along the Dnieper River (1025), with Kiev and the territories of the right bank falling to Yaroslav. On Mstislav's death without issue (1036), Yaroslav became undisputed ruler of all Russia.

Yaroslav warred against the Baltic and Finnic tribes, the Poles, the Turkic Pechenegs of the Steppe (ending in decisive victory in 1036), and Byzantium (the unsuccessful plundering raid of 1043). The most notable achievements of his reign, however, were internal. The Christian faith established by his father (987/988), was propagated through the spread of book learning (Kievan commission for translations from Greek into Slavic); and church architecture attained a high level. Among the outstanding structures of the period were the monasteries of St. George and of St. Irene and the Church of the Annunciation, in Kiev; the Church of St. Sophia (1045), in Novgorod; and above all, the magnificent Church of St. Sophia (c. 1037), in Kiev, containing the best-preserved examples of early 11th century Byzantine art to be found anywhere. Letters flourished also, as witnessed by Metropolitan Hilarion's *Sermon on Law and Grace* (c. 1040/1050), a work equal in quality to its Byzantine models. Some laws were written down: the core of the first recension of the "Russian Law" (*Pravda Russkaya*) may go back to Yaroslav's time. Under Yaroslav the Kievan state lived through one of its two periods of greatness.

Judging by Hilarion's *Sermon* and the St. Sophia mosaics with their Greek inscriptions, Kiev's orientation under Yaroslav was Byzantine. This, however, is only part of the truth. Byzantium was defied militarily, and perhaps even ecclesiastically since Hilarion was a native of Kiev and was elected metropolitan there. Marriage alliances in Yaroslav's family were often Western: his wife was the Swedish princess Ingigerdr Irene, and his daughter Anna was married to the French King Henry I. The German Emperor Henry II was Yaroslav's ally in 1017. Contacts with Scandinavia continued: Yaroslav survives in Norse sagas, and kings of Norway spent some time at his court, which must have had an international flavor. His sarcophagus and skeleton are preserved in the Church of St. Sophia at Kiev.

IHOR ŠEVČENKO.

Professor of History, Columbia University.

YAROSLAVL, yī-rə-sláv'əl-yə, oblast, USSR, in the central industrial region of the Russian SFSR, northeast of Moscow Oblast. Its area of 14,200

square miles, drained by the upper Volga River, lies in the forest zone, with infertile gray-brown soils. The oblast produces peat, lumber, and building stone, and its farms yield flax, potatoes, vegetables, and dairy products. During 1937-1941 dams were constructed on the Volga at Uglich and Rybinsk, the latter leading to the formation of the Rybinsk Reservoir. Small hydroelectric stations are in operation at both sites. Formerly a center of linen milling established in the 18th century, the oblast now has diversified industries including the manufacture of machinery and automobiles, shipbuilding, and chemical plants. Fisheries are maintained on the Volga River and at the Rybinsk Reservoir. The oblast was formed in 1938 out of Ivanovo Oblast. Its capital is the city of Yaroslavl (q.v.). Pop. (1961) 1,392,000.

W. A. DOUGLAS JACKSON.

YAROSLAVL, city, USSR, in the Russian SFSR, on the upper Volga River, about 150 miles north-east of Moscow. The city, capital of Yaroslavl Oblast, forms part of the central industrial region, of which Moscow is the core. Yaroslavl is situated at the junction of the Moscow-Archangel and Rybinsk-Kostroma railway lines. A river port, the city stretches about 15 miles along the right bank of the Volga where the latter is joined by the small Kotorosl River. Yaroslavl is noted for its manufacture of synthetic rubber, rubber tires, resin- asbestos materials, chemicals, and trucks. It also produces machinery, cotton and linen textiles, and foodstuffs. An oil refinery was opened in 1960, and on the left bank of the Volga there is a thermal-electric plant, run on peat.

A kremlin was built at the mouth of the Kotorosl sometime between 1010 and 1025 A.D. to strengthen the defenses of the Kievan Russian state against the raids of the Pechenegs, and the town was named after Yaroslav the Wise, prince of Kiev. Despite its river location, Yaroslavl's development was slow during the 11th and 12th centuries, but it became an important center of religious culture. In one of Yaroslavl's monasteries the manuscript of the 12th century tale, *The Word of the Campaign of Igor*, was found.

In 1238 Yaroslavl was sacked by the Mongol-Tatars in their sweep over much of Kievan Russia. Two centuries later, in 1463, Yaroslavl accepted the overlordship of the rising Muscovite principality.

When the Mongol-Tatar yoke was finally lifted, Yaroslavl's fortune began to improve. The city's position on the upper Volga afforded it great commercial advantages, particularly when, in the latter 16th and 17th centuries, the Volga River became a major trade artery with Central Asia and the East. The development of trade between west European countries and Muscovy by way of the White Sea also benefited Yaroslavl, which lay on the cart road connecting Archangel with Moscow. One of the famous churches built during this period is the Church of St. John Chrysostom in Korovniki (1649-1654), which shows a blending of Eastern and Western styles; its use of colored tiles suggests a Dutch influence.

The opening of the Gulf of Finland and the subsequent building of St. Petersburg by Peter the Great at the beginning of the 18th century siphoned off the trade that had hitherto passed through Yaroslavl. In the mid-19th century the population was only about 27,000. During the period of Soviet rule, however, the city has once more enjoyed a rapid growth. It possesses a philharmonic orchestra and a fine dramatic theater, founded in 1750. Pop. (1959) 407,000.

W. A. DOUGLAS JACKSON,
Professor of Geography, University of Washington.

YARRA RIVER, yā'r'a (formerly YARRA YARRA RIVER), river, Australia, in southern Victoria. It rises in the Great Dividing Range and flows 115 miles in a westerly direction into Hobson's Bay, the northern arm of Port Phillip Bay. The city of Melbourne is situated on its banks, near the mouth. The upper reaches of the river are noted for their scenic beauty and constitute a popular vacation area. The Upper Yarra Dam, completed in 1957, is 64 miles above Melbourne. The river was discovered by Charles Grimes in 1803 and named by John H. Wedge in 1835. The name means "running water" in the aboriginal language.

An old city with many historic sites, today Yaroslavl is a growing part of an industrial region.

Sovfoto

Yarrow (*Achillea millefolium*), or milfoil, is a weed commonly found in fields and on roadsides.

YARROW, yar'ō, a perennial plant, *Achillea millefolium*, of the composite family (Compositae). Yarrow (or milfoil) grows to a height of 3 feet (1 meter), has small white or pink flowers borne in flat-topped clusters up to a foot (0.3 meter) across, and aromatic fernlike leaves, which are 1 to 6 inches (2.5 to 15 cm) long and are alternate on the stem. Yarrow is native to Eurasia but occurs as a weed elsewhere. The plant spreads by seeds and by underground runners. It can be a pernicious pest in lawns, and cattle that eat it may yield off-flavored milk. Pink-flowered yarrow is grown as an ornamental. Yarrow is used to some extent in folk medicine; research indicates that it may have value for its hemostatic and anti-inflammatory properties. *Achillea*, the genus to which yarrow belongs, was named for Achilles, who reputedly discovered the medicinal virtues of the plant. Some botanists consider certain native North American members of *Achillea*, for example *A. lanulosa* and *A. borealis*, to be varieties of *A. millefolium*.

JOHN W. THIERET
Northern Kentucky University

YARROW RIVER, yar'ō, a river in the Borders region of Scotland, rising just northeast of the town of Moffat. The Yarrow River, also called Yarrow Water, flows in a generally east-northeasterly course for 24 miles (38 km) through the Loch of the Lowes and St. Mary's Loch. It enters Ettrick Water, a tributary of the river Tweed, about 2 miles (3 km) southwest of Selkirk town. Noted for its beauty, the river has been celebrated in poems by Sir Walter Scott, William Wordsworth, and James Hogg, who was known as the "Ettrick Shepherd."

YASNAYA POLYANA, yāz'nə-yə pāl-yā'nə, the former home of the Russian writer Leo Tolstoy, 115 miles (185 km) south of Moscow. The name means "clear glade." The present grounds, which are open to the public, form part of a larger estate that Tolstoy inherited from his mother. The chief point of interest is the house where Tolstoy lived during his marriage (1862–1910). His unmarked burial place lies in the woods nearby. Also on the grounds are his mother's family mansion and a literary museum occupying a former house that Tolstoy had converted into a village school.

YASTRZEMSKI, yə-strem'skē, Carl (1939–), American baseball player, who established American League records for most games (3,308) and times at bat (11,988). His 23 seasons with the Boston Red Sox set a major league record for service with one team.

Yastrzemski was born in Southampton, N.Y., on Aug. 22, 1939. Signed by Boston in 1959 after a year at Notre Dame, "Yaz" had two outstanding seasons with the Raleigh (N.C.) and Minneapolis farm clubs. He was then given the task of taking over in left field for Ted Williams, who had retired in 1960. By 1963 he won his first of three batting titles, with .321, and established a reputation as a brilliant outfielder, leading to seven Gold Glove awards. He was also the AL batting leader in 1967, with .326, and in 1968, "the Year of the Pitcher," with .301.

In 1967 he led the Red Sox to their "Impossible Dream" pennant following a ninth-place finish in 1966. He won the Most Valuable Player award and was one of a select group in history to achieve a Triple Crown, leading the AL in batting average and runs batted in (121) and tying for the lead in home runs (44).

Although he seldom approached his 1967 success, Yaz made the AL All-Star team 18 times. He was also the first in AL annals to amass combined career totals of 3,000 hits (3,419) and 400 home runs (452). He hit over .300 six times, with a lifetime average of .285. Yastrzemski was elected to the Hall of Fame in 1989.

"Baseball's Best: The Hall of Fame Gallery"

YATES, Richard, American political leader: b. Warsaw, Ky., Jan. 18, 1815; d. St. Louis, Mo., Nov. 27, 1873. He received the first diploma issued at Illinois College in Jacksonville, Ill. (1835), studied law at Transylvania University, and was admitted to the bar in 1837. He then practiced law in Jacksonville, was a member of the state legislature during most of the 1840's, and from 1851 to 1855 was a Whig member of Congress. A staunch opponent of slavery, Yates joined the new Republican Party and was governor of Illinois throughout the Civil War, from 1861 to 1865. In this key position he gave invaluable support to President Abraham Lincoln's war policies, working tirelessly to mobilize the full resources of the state for the Union military effort. When the Peace Democrats in the Illinois General Assembly adopted a resolution calling for a negotiated peace, Yates dismissed the legislature (1863). He also had the distinction of giving Ulysses S. Grant his first Civil War commission in 1861. After the war, as a United States senator (1865–1871), Yates aligned himself with the Radical Republicans and voted to impeach Andrew Johnson.

YATES, Robert, American political leader and judge; b. Schenectady, N.Y., Jan. 27, 1738; d. Albany, Sept. 9, 1801. After studying law, he practiced in Albany, where he earned a reputation as a solid though not brilliant attorney. When conflicts developed with Britain, Yates unhesitatingly chose the colonial side. He pushed for independence at the New York provincial congresses of 1775 and 1776, was a member of the Committee of Safety chosen by the latter, and in 1777, after helping to prepare the first state constitution, became a justice of the New York Supreme Court. Later, in the 1790's, he served as chief justice of the court.

Yates is chiefly remembered as an anti-Federalist, joining his friend George Clinton after the War of Independence as an advocate of states' rights as against national power. This was the view he represented as a delegate to the Constitutional Convention in Philadelphia in 1787. When his colleague Alexander Hamilton asked for greater powers for the federal government, Yates urged that authority remain with the states. Leaving the convention before adjournment, he opposed ratification of the new Constitution on these grounds; but when the Hamilton forces won out at the New York State ratification convention, Yates accepted defeat gracefully. "It would be little short of treason," he said, to continue resistance after the Constitution had been adopted.

Taking this position, Yates drifted away from Clinton. In 1789 he ran against the latter for governor, with Hamilton's support. Defeated in this contest, he lost again in 1795, being beaten narrowly by John Jay. Thereafter he faded gradually from the political scene. His notes on the Constitutional Convention of 1787 were published in 1821.

University of Wisconsin

YATSUSHIRO, yā-tsōō-shē-rō, a city in Japan, situated on the alluvial fan of the Kuma River, 22 miles (35 km) by rail south of Kumamoto, in Kumamoto prefecture, on the island of Kyushu. Originating as a transportation and traffic center on the Kuma River during the feudal period, Yatsushiro became a castle and local market town between the 17th and 19th centuries. It grew into an industrial center with the advent of large modern factories: a hydraulic cement plant was established in 1888, a pulp and paper mill in 1924, a rayon textile factory and a brewery in 1937, and a ramie textile plant after World War II, all of which were attracted by the plentiful supplies of raw materials and labor that were available in the area. The city is famous for its Kodayaki porcelain, first made by Korean potters who came to Japan during the 16th century. Population: (1985 census) 108,790.

GEORGE H. KAKIUCHI
University of Washington

YAVAPAI INDIANS, yā'və-pī, a North American Indian tribe, whose language belongs to the Yuman language family. The Yavapai formerly inhabited lands around the Verde River, from Bill Williams Mountain to the Salt River, in central and west central Arizona. The meaning of their name is unclear.

In 1582 the Spanish explorer Antonio de Espejo visited them and estimated their population at 1,500. The popular name Mojave Apache has

been applied to them and is a cause of considerable confusion, since they are in no way related to the Apache peoples: the appellation originally arose from their warlike disposition. The Yavapai offered resistance all through the period of early American occupancy of their area. As a result they were forcibly removed to the San Carlos Reservation in 1875, but gradually drifted back to their homeland, centering on the abandoned Camp (now Fort) McDowell Military Reservation. The United States turned this territory over to the tribe in 1903.

In 1910, Camp Verde was established for Yavapai use; by 1916 nearby Middle Verde had been added to their lands. Another reservation was established at Prescott in 1935 and expanded in 1956, and in 1969 a smaller tract at Clarksdale was added to Yavapai territory. Longstanding U.S. government plans to build the Orme Dam, which would have resulted in the flooding of a large portion of the Fort McDowell reservation, were finally abandoned in the 1980's.

FREDERICK J. DOCKSTADER*

Author of "Great North American Indians"

YAWATA. See KITAKYUSHU.

YAWL, yōl, a small ship's boat, usually propelled by four or six oars and schooner-rigged. The name is also applied to a jolly boat, a small fishing boat, and to a sailboat similar to a sloop but also carrying a small sail, called the mizzen, at the stern.

YAWS, yōz, an infectious tropical disease, also called pian or frambesia, prevalent in the West Indies, South Pacific islands, Africa, and South America. It is caused by a spirochetal microorganism (*Treponema pertenue*) similar to that producing syphilis. The disease is usually acquired early in childhood by direct contact with the open infectious ulcers of other individuals with this illness. It is associated with poor personal hygiene and in some instances is thought to be spread by flies. The disease is similar in many respects to syphilis, and some authorities believe that the two diseases were at one time identical but became modified by environmental factors. Both illnesses produce a positive blood test with the Wassermann reaction, and both respond to treatment with penicillin. In humans and experimental animals the presence of one disease usually produces immunity to the other disease.

The clinical manifestations of yaws usually appear after an incubation period of approximately one month. The initial lesion, the mother yaw, consists of a small growth, often on the legs, which later ulcerates and then heals with scar formation. Two or three months later a generalized skin rash develops, consisting of large lesions over the skin of the face, neck, and extremities. This skin eruption eventually heals spontaneously, but penicillin treatment produces rapid improvement. Yaws often appears on the soles of the feet, producing painful ulcerations known as "crab yaws." Several years after the onset of infection, the disease, if untreated, may produce destructive changes in the bones of the hands, arms, and legs. The bridge of the nose may be destroyed, and severe ulcerative changes may occur in this area.

The diagnosis of yaws may be made by the characteristic appearance of the skin eruptions.

but the spirochetal organism is readily demonstrated in the infectious ulcerations. The Wassermann and other blood tests for syphilis are usually positive. Treatment of the disease consists of a single or several injections of penicillin. This antibiotic produces almost complete recovery in the great majority of patients and is the treatment of choice. An extensive program for the treatment of large population groups with this illness has been carried out throughout the world by the World Health Organization.

Duke University Medical Center

YAZD, yāzd, a town in central Iran, about 410 miles (655 km) southeast of Teheran. It lies at an elevation of about 4,000 feet (1,200 meters) in a long valley bordered by high ranges. Its name is an ancient Iranian word for "God." The town is situated on a major highway leading from Teheran to the extreme southeast of Iran and on the line of a railway that parallels the highway. A modern airport is adjacent.

Yazd (Yezd) is the agricultural center of a district that is generally far from fertile. Rainfall is so scanty that all crops must be irrigated. Water for this purpose is brought in underground canals from the snowcapped ranges in the area or, more recently, derived from the flow of deep wells. There are many orchards in the surrounding country, and cotton is also grown. For centuries fine carpets, silk piece goods, and delicate shawls have been woven on family looms in the town. Copper is mined and processed in the vicinity.

Yazd is dominated by the lofty twin minarets that flank the entrance to the old congregational mosque. Hundreds of tall wind towers, which direct the prevailing breezes into the houses, resemble minarets and have brought Yazd the nickname of the "abode of devotion."

The site is a very ancient one, famous in Sasanian times (3d to 7th centuries A.D.), and after the conversion of Iran to the Muslim religion it remained a stronghold of the older Zoroastrian faith. Its colony of Zoroastrians, renowned as gardeners and irrigation experts, is the largest in the country. Their dead are exposed to the elements within high-walled, circular structures. Population: (1986 census) 234,003.

Coauthor of "Iran Past and Present"

YAZIDIS, yā'zə-dēz, a religious sect of Kurdish-speaking people, centered mainly in the Mosul area of Iraq and around Kilis and Gaziantep in southern Turkey. Their number is estimated at between 40,000 and 70,000. Modern scholars believe the sect is of Muslim origin, descending from supporters of the Umayyad caliph Yazid I (reigned 680–683). The Yazidis (Yezidis) are popularly known as devil worshippers, but this is a misnomer; it would be more correct to think of them as angel worshipers, since they consider Satan (Malak Taus) to be an angel who has fallen but will be restored for his repentance. The Yazidi scriptures are in Arabic, but the tradition is passed on in Kurdish, the language of prayer. The religion is synthetic, including Judaic, Christian, Islamic, and Zoroastrian elements. Saturday is the day of rest, Wednesday the holy day. There is also an annual pilgrimage to the tomb of Sheikh Adi (about 1160), the Yazidis' major saint, north of Mosul.

The Yazidis remain aloof from their neighbors and seek no converts. They are mostly farmers, although nomadic Yazidi tribes exist. Their society is divided into laity and clergy, the latter hierarchically organized. Contrary to popular belief, the Yazidis value cleanliness and are of high moral caliber.

NORMAN ITZKOWITZ, *Author of*
"Ottoman Empire and Islamic Tradition"

YAZOO CITY, ya'zōo, a city in west central Mississippi, the seat of Yazoo county, on the Yazoo River, about 40 miles (64 km) northwest of Jackson. Among the city's manufactures are cottonseed oil, lumber products, fertilizer, and clothing. An oil field was discovered nearby in 1939, and the city has an oil refinery.

Founded in 1824 as Hanan's Bluff, the city prospered as a river port and was incorporated as Manchester in 1830; the name was changed to Yazoo City in 1839. During the Civil War it was the site of a Confederate navy yard and was twice burned though not held by Union forces in 1863. Population: 12,427.

YAZOO LAND FRAUD, ya'zōo, a transaction by which, in 1795, the Georgia legislature sold approximately 35 million acres (14 million hectares) of land, situated in what are now the states of Alabama and Mississippi, to four land companies for \$500,000. The sale became a national scandal when it was learned that it had been procured by wholesale bribery of the legislators.

A new legislature passed an act in 1796 rescinding the sale and ceremoniously burned the 1795 act. In litigation over the validity of titles purchased from others who had taken title from the original grantees, the U.S. Supreme Court ruled in 1810, in the historic case of *Fletcher v. Peck* (6 Cranch 87 [1810]), Chief Justice John Marshall writing the opinion, that the act of 1796 rescinding the 1795 grant was unconstitutional. The case was a constitutional landmark for the following reasons: (1) it was the first instance in which the U.S. Supreme Court held a state statute invalid because of conflict with the U.S. Constitution; (2) it established that a public grant is a contract subject to the provision in the federal Constitution prohibiting states from impairing the obligation of contracts; and (3) in connection with a question as to the validity of the 1795 act, it rejected the principle that a legislative act can be declared invalid because of corrupt motives of legislators who enacted it. Georgia meanwhile had ceded its interest in the Yazoo lands to the United States in 1802. The controversy was finally resolved by an appropriation of over \$4 million by Congress in 1814 to indemnify parties claiming lands pursuant to the Georgia act of 1795.

C. DOUGLAS SANDS, *University of Alabama*

YAZOO RIVER, ya'zōo, a river in west central Mississippi, formed by the junction of the Tallahatchie and Yalobusha rivers near the city of Greenwood. It flows 189 miles (304 km) in a southwesterly direction, meeting the Mississippi River at Vicksburg. The Yazoo is navigable. The area between the Mississippi on the west and the Yazoo and its tributaries on the east—about 65 miles (105 km) wide and 200 miles (322 km) long from Memphis, Tenn., to Vicksburg—is known as the Yazoo Delta. Subject to periodic floods, it is famous for long-staple cotton.

YEADON, yā'dən, borough, Pennsylvania, in Delaware County, immediately west of Philadelphia, of which it is a residential suburb. The place was named Yeadon in 1870 after Yeadon Manor, the residence of a prominent citizen, who named it for the home town of his parents in England. Points of interest are the Enoch Bonsall House (1763) and the Palmer Homestead (1774). Yeadon was chartered as a borough in 1894. Government is by mayor and council. Population: 11,980.

GERTRUDE M. BOSSARD
Yeadon Public Library

YEAR, yīr, a unit of time intended to equal the period of revolution of the earth around the sun. Prior to 4000 B.C. the Egyptians established the length of the year as 365 days by counting the days that elapsed between two successive heliacal risings of the star Sirius; that is, two successive appearances of Sirius just before sunrise, each occurring after a period of invisibility caused by its nearness to the sun. Astronomers distinguish several kinds of year, of which three—the tropical, sidereal, and anomalistic—are most common.

The *tropical year*, also called *solar year* or *equinoctial year*, is the year to which the Gregorian calendar is adjusted. It is the interval between two successive returns of the sun to the vernal equinox and is approximately equal to 365.24220 mean solar days, or 365 days 5 hours 48 minutes 46 seconds. Since 1956 the tropical year has been the interval in terms of which the second, the fundamental unit of time in the several systems of units employed in physics and engineering, is defined. In that year the International Committee on Weights and Measures redefined the second as $1/31,556,925.9747$ of the tropical year for Dec. 31, 1899 (called January 0, 1900, in astronomical literature) at 12 hours ephemeris time. It was necessary to use a specific date because the length of the year is not precisely constant: the tropical year is slowly decreasing in length, while the sidereal and anomalistic years are slowly increasing. The rate of change, however, is less than 1 second per century.

The *sidereal year* is the average period of revolution of the earth with respect to the fixed stars; its duration is 365.25636 mean solar days. The *light-year*, a unit used to express stellar distances, is the distance light travels in 1 sidereal year; it is equal to 5.879×10^{12} miles. The *anomalistic year* is the average interval between successive closest approaches of the earth to the sun; its length is 365.25964 mean solar days.

The calendar year for the Gregorian calendar consists of 365 days (366 in leap years) and is divided into 12 months. It begins on January 1 and ends on December 31. Since the length of the tropical year is nearly $365\frac{1}{4}$ days, it is necessary once every 4 years (with certain exceptions; see **LEAP YEAR**) to add a day to the calendar year. This day, which falls on February 29, is known as leap day.

YEARDLEY, yārd'lē, Sir George, English governor of Virginia: b. London, England, c. 1587; d. Jamestown, Va., buried Nov. 13, 1627. He was trained as an officer with the English Army in the Netherlands and in 1609 sailed for Virginia as

captain of the guard for Sir Thomas Gates. He was appointed to the council in 1611 and served as acting lieutenant governor from April 1616 to 1617, when he returned to England. On Nov. 18, 1618, he was commissioned governor and captain general of Virginia, succeeding Lord De La Warr, and on November 24 was knighted by James I. The Virginia Company instructed him to divide the land by a set formula and to set up a civilian government.

Yeardley reached Jamestown in April 1619 and on July 30 organized the General Assembly of Virginia, the first representative assembly in the New World. Before his term expired, he asked for a successor in order to devote his time to private business. He became a member of the council under Sir Francis Wyatt in November 1621 and marshal in 1622. In 1625, the year after the charter of the Virginia Company was annulled and Virginia became England's first crown colony, Yeardley went to England to petition the king to let Virginia keep her form of government. He returned to Jamestown in April 1626 with a commission as royal governor to succeed Wyatt and continued in office until his death. He was buried on Nov. 13, 1627.

NORA MILLER TURMAN
Author of "George Yeardley"

YEASTS, yēsts, microscopic, single-celled, colorless plants. They are true fungi, with round or oval cells that are much larger than bacteria. The characteristic method of reproduction is budding, in which a small swelling occurs at the edge of the cell, gradually enlarges, and at maturity separates from the parent cell by constricting at its base. In some species, buds are slow in breaking free and thus form clusters of cells. The spores produced by true yeasts are a means of survival rather than reproduction. Definite classification of the yeasts and imperfect yeasts is still unsatisfactory from a botanical standpoint, and the term "yeast" is often used to refer to species in both groups.

Yeasts, widely distributed in nature, are found on the fruit and leaves of plants and in the soil. Nearly all yeasts adapted to use by man are in one genus, *Saccharomyces*, with *S. cerevisiae* the most prominent species. Uses of yeasts are based on their ability to ferment sugar solutions or their nutritional and medicinal values.

Fermentation processes are as old as history and were highly developed before the advent of scientific methods. The modern industries of bread making, brewing, spirits and industrial alcohol manufacture, and wine making, however, owe their foundations to the work of Louis Pasteur (q.v.) in the mid-19th century. The food, feed, and medicinal uses of yeasts were found later as knowledge of vitamins and metabolism unfolded. They have been widely hailed as therapeutic agents. The quantities of yeasts grown annually are measured in the hundreds of million pounds.

The procedures for growing yeasts are fundamentally the same in each industry. A pure culture is obtained by isolating a single yeast cell and growing it on a nutrient medium consisting of sugars (molasses, starchy grains, potatoes), a source of nitrogen (ammonia, grain steepwater), minerals, and water of controlled acidity. As growth proceeds, the culture is transferred to successively larger batches of medium until the final batch often exceeds 100,000 gallons. When growth is completed, the yeast cells are separated

The Distillers Company Ltd

Photomicrographic sequence of yeast cell budding. Cells are nurtured on sugars, a nitrogen source, minerals, water.

from the spent medium.

Yeasts grown for bread making, food, feed, and medicinal purposes are the primary product of the fermentation process and produce little alcohol. The spent medium is the byproduct and is discarded after centrifuging out the yeast cells. Yeasts grown during fermentations for beer, ale, spirits, wine, and industrial alcohol, however, are the byproducts, while the spent medium becomes the final consumer product.

Types.—*Baker's yeast* is a strain of *S. cerevisiae* grown on a medium of molasses and ammonia or molasses and grain extracts. The yeast rapidly ferments the sugars derived from the starch in the flour to produce carbon dioxide gas which leavens the dough.

Brewer's yeasts are strains of *S. cerevisiae* that slowly ferment the extract of malt, cereals, and hops to produce beer (bottom-fermenting yeast) or ale (top-fermenting yeast). After separation from the spent medium, these yeasts are dried for animal feed or refined before drying for use in food and medicine.

Spirits and industrial alcohol yeasts are strains of *S. cerevisiae*, and sometimes other species, that ferment molasses, grains, or other sugary material. After separation from the spent medium, yeast and fermentation residues are dried together for animal feed.

Wine yeasts are strains of *S. cerevisiae* var. *ellipsoideus* that ferment grape juice. Here the yield of yeast is too small to be salvaged economically.

Food (and feed) yeast production, stimulated by shortages in two world wars, reaches large proportions in Europe. Although several species of yeasts have been grown for food use, only strains of *S. cerevisiae* and *Candida utilis* are cultivated in the United States. *C. utilis* is better able to utilize sugars from waste sulphite liquor from wood pulp manufacture. Dried yeasts are used as nutritional supplements in a number of foods in the United States.

Medicinal yeast was first recognized by the United States Pharmacopeia in 1944 as the non-fermentable "dry cells of any suitable strain of *S. cerevisiae*," with a second species, strains of *C. utilis*, added in 1956. Yeast is a rich source of the B-complex vitamins, and its protein is well balanced in amino acids. Yeast or a yeast deriva-

tive, ergosterol, acquires vitamin D₂ activity after irradiation with ultraviolet light. Other yeast derivatives are used in the medium in which antibiotic-producing organisms are grown and as a starting point in the synthesis of steroid hormones.

The chemical composition of yeasts varies with the species and growing medium. Dried yeasts have been found to assay: protein, 45 to 55 percent; fat, 0.5 to 2.5 percent; ash (minerals), 5 to 7 percent; carbohydrates, 35 to 45 percent; and moisture, 4 to 6 percent.

YEATS, yáts, Jack Butler, Irish painter: b. London, England, Aug. 23, 1871; d. Dublin, Ireland, March 28, 1957. He was the son of the artist and wit John Butler Yeats (1839–1922) and the brother of William Butler Yeats (q.v.). Most of his childhood and youth he spent in Sligo and the west of Ireland, where the living oral traditions and vivid folk imagination had a lasting influence on him. He was privately educated in Sligo. Later he moved to England but returned each summer to Ireland.

Yeats' early work, water colors and drawings of Irish genre, was part of a minor renaissance in Irish painting that accompanied the greater flowering in literature. He particularly enjoyed representing individuals whose lives had some element of risk—gypsies, clowns, pugilists—and was inspired by some of the romantic figures of his country's political past—Wolfe Tone, Robert Emmet, and Charles Stewart Parnell. He reached maturity in the early 1920's, when the color and atmosphere in his paintings took on a new license that transformed his subjects—many of them now taken from city life. Until around 1937 he pro-

duced paintings that fuse high poetry and acute observation, reclaiming mundane subject matter in romantic terms. Much of his best work was done at this time.

In 1937, somewhat disillusioned by the new Ireland and moved by the threat of war, Yeats started a series of allegorical paintings, beginning with *Helen* (Tel Aviv Museum) and ending 14 years later with *Basin in Which Pilate Washed His Hands* (1951, private collection). In this series he celebrated public and private tragedies with a resonant dignity, touched by wildness. A master of suggestion, he occluded his symbols so that they remain highly personal but fruitful in an odd, antic way. After 1951 his work, while uneven, reached new heights of lyric inspiration. His color was more agitated and broken; painting entirely with the knife, he leaned more and more on suggestion than on statement. He returned to his early themes of the clown, gypsy, and beggar. Some of this late painting is remarkable for its piercing and pure intensity.

Yeats had little concern for public success and refused to nourish his reputation, but he is the greatest of modern Irish artists and a highly individual figure. His work is intensely lyrical and romantic, with expressionist overtones, and it is unusual in modern art for its insistence on a joyous and exuberant vitality. Predominantly a colorist, he admired Jean Antoine Watteau, Honoré Daumier, and Venetian painting but firmly denied any influence on his own art. He also wrote a number of vivid novels and plays that show his interest in the individual and wayward characteristics that to him illuminated human nature.

BRIAN O'DOHERTY,
Art Critic, New York "Times."

YEATS, William Butler, Irish poet, dramatist, and essayist; b. Dublin, Ireland, June 13, 1865; d. Cap-Martin, France, Jan. 28, 1939. His grandfather and great-grandfather were rectors in the Church of Ireland (Protestant), but his father, John Butler Yeats, broke away by becoming a skeptic in religion and a portrait painter by profession. Yeats spent much of his childhood in Sligo, a port town in the west of Ireland where his mother's relatives lived. The landscape of this region was always his favorite, and it served him as the setting for many of his poems.

In 1874 the family moved to London, where they longed for Ireland, and in 1880 they returned to Dublin. Yeats was at this time heavily under his father's influence, which was rationalistic as well as artistic; but partly in filial revolt he began, near the end of his attendance at high school, to show a fascinated interest in the study of occult phenomena. He attended art schools in Dublin from 1884 until 1886, when he committed himself to a literary career.

Irish Literary Revival.—Yeats found everywhere, in Irish folklore, in poetry, and in mystical writings, support for his conviction that literature should concern itself with the dreaming as well as the conscious mind and should rebel against the encroachments of science upon imagination. He gained more adherents to another aspect of his thought, a belief that all art should be national. In the early 1890's he founded Irish literary societies in both Dublin and London and almost at once became the leader of a school. He urged Irish writers to use Irish landscape, to take themes from Irish legends and sagas, to saturate their work in whatever was local and therefore inti-

mate. On these principles he wrote his first book, *The Wanderings of Oisín and Other Poems* (1889), and his first important play, *The Countess Kathleen* (1892). A few years later he and Lady Gregory joined talents to start a new dramatic movement in Ireland, resulting in the founding of the Abbey Theatre in 1904. Yeats was the major influence upon this world-famous theater for the rest of his life, although some of its playwrights, notably John Millington Synge and Sean O'Casey, scored greater popular successes with their plays than he did.

Poetic Development.—Yeats was one of the first poets in English to make deliberate use of symbolism, so that all his work is closely bound together by an elaborate context of implicit meanings. His poetic development may be divided into two stages. The first, which lasts until about 1900, is characterized by otherworldly and ecstatic themes and slow-paced rhythms. It is associated with his unrequited love for Maud Gonne (1866–1953), a beautiful Irish patriot; his passion for her is idealized to become part of a search for perfection. In the second stage, Yeats takes account of elements that he had previously excluded; his writing is more physical, combative, and salty. He is more aware of imperfection and often indignant with it. Instead of *The Shadowy Waters* (1900), he writes *Responsibilities* (1914). His diction comes closer in this second stage to ordinary speech.

William Butler
Yeats

Radio Times Hulton
Picture Library

The strength and solidity of Yeats' verse increased as he grew older. These qualities were buttressed by his late marriage, in 1917, to Georgie Hyde-Lees, an Englishwoman, with whom he lived chiefly in Dublin and at their old Norman tower, Thoor Ballylee, in the west of Ireland. They had a son, Michael, and a daughter, Anne. When the Irish Free State was formed, Yeats was appointed one of its first senators (1923–1928), and in 1923 he received recognition of a more international kind by the award of the Nobel Prize for literature.

In the poetry he wrote after his marriage Yeats shared more fully than before the aspirations, regrets, and grievances of the contemporary world. Although his early books continue to have their admirers, he is best known by books written later, especially by *The Tower* (1928), *The Winding Stair* (1933), and *Last Poems* (1940). Here he expressed most memorably his powerful feelings about the possible ruin of civilization, about old age and youth, about moments of sudden illumination and joy, and about the unending debate that goes on within the mind as opposing

passions struggle to master each other.

Basic Themes.—Yeats' work deals intensely with three basic urges. The first is to be in the midst of things, to live with the delight, ebullience, and versatility of a Renaissance man. Running counter to this is a second urge, to rise above the melee, to contemplate rather than merely to act, to sift wasteful life for its economical, artistic essence. There is a third urge, which Yeats repudiates, although he gives it expression, and this is to seek goodness alone, to become as bodiless as possible both on earth and in heaven. This is the way of the saints, and when faced with it Yeats prefers to stand with "Homer and his unchristened heart." Much of the effect of his verse comes from its moving affirmation—over frankly admitted obstacles and doubts—of intense, unified, imaginative life.

YECLA, yä'klä, city, Spain, in the northeast corner of the Province of Murcia, on the Juá River, a tributary of the Segura. It is connected with Murcia, the capital, by rail and highway. The surrounding countryside is mountainous and has numerous streams. There is some manufacture of soap and sandals, but agriculture is the main occupation, producing grains, wines, and olive oil. There are two mineral springs, Fuente del Álamo and Fuente de la Negra. Yecla is an old city, and the countryside contains the ruins of several fortresses. In 1813 the city was the scene of a fierce battle in which the French defeated the Spanish defenders and won control of the region. The city figures prominently in the writings of the modern Spanish essayist and novelist Azorín (José Martínez Ruiz). Pop. (1950) 24,046.

YELLOW, yél'ô, the prismatic color that lies between red and green in the color spectrum. The electromagnetic radiation that gives the sensation of yellow has a wavelength centered at about 5750 angstroms, although this value varies somewhat from one person to another. The human eye is extremely sensitive to yellow (the peak of the color-sensitivity curve falls between yellow and green), and it is probably for this reason that yellow signs and markers are widely used to indicate caution or danger.

Yellow filters, which absorb blue and violet light and transmit red and green light, are the most useful photographic filters. Yellow dyes and pigments have numerous applications; for information on these see COLOGNE YELLOW; COLOR; DYES AND DYEING; NAPLES YELLOW; OCHER; PAINT. See also COLORS, SYMBOLIC; LIGHT.

YELLOW BOOK, an illustrated quarterly published in London by John Lane from 1894 to 1897. The American novelist Henry Harland was literary editor, but the decadent tone of the periodical was set by the brilliant young illustrator Aubrey Beardsley, its art editor during the first two years. Among *fin de siècle* writers and aesthetes who contributed to the *Yellow Book* were Max Beerbohm, Frederick William Rolfe, Arthur Symonds, John Davidson, Ernest Dowson, and Lionel Johnson. The poets William Watson and William Butler Yeats and the novelists Henry James and George Moore also were contributors. Apparently to conciliate his critics Lane sought to add more conservative writers and literary historians such as George Saintsbury, Edmund Gosse, Richard Garnett, Austin Dobson, and Henry Duff Traill. The original brilliance of the publication thus dwindled, and after the 13th issue the quarterly folded.

WILLIAM BRACY.

YELLOW-EYED GRASS, the common name given to many species of plants in the genus *Xyris*, of the family Xyridaceae. It is not a grass, but the narrow leaves that sheath the base of the leafless scape (stalk) give it a grasslike appearance. *Xyris* (from *xyron*, razor) is a Greek name for a plant with 2-edged leaves. The flowers (usually yellow) are borne in a head at the end of the scape, which arises from a bulbous or non-bulbous rootstock along with the basal leaves. The individual flowers have 3 sepals, 3 petals, 3 fertile stamens, and 3 staminodes, with a 3-carpellate, 1-locule superior ovary that becomes a 3-valved loculicidal capsule at maturity. The genus is most common in subtropical or tropical America and occurs in Africa, Australia, and India; about 20 species grow in North America from Newfoundland to Florida and westward to Texas, and along the St. Lawrence River and Great Lakes. The North American species are often found in bogs or swamps or along the edges of ponds; a few are true aquatics and grow in swift-flowing streams. Two of the most common North American species are *X. flexuosa* and *X. torta*, both of which have bulbous rootstocks, 2-ranked linear twisted leaves, and 2-edged twisted scapes. The yellow flowers of *X. flexuosa* are more conspicuous because of the long-fringed lateral sepals projecting beyond the bracts. *X. fimbriata*, a plant with strap-shaped leathery leaves, also has sepals that are conspicuously fringed and projected. Economically the family is of little importance. Two species are used in aquatic gardening and aquariums, and the foliage and roots of three species have been used as a remedy for leprosy and some skin irritations in Brazil, the Guianas, and India.

YELLOW FEVER (also known as **YELLOW JACK**), an acute infection of man, caused by a virus and transmitted to man by the bite of an infected mosquito. The name follows from the deep jaundice observed in the seriously ill human. The Spanish name *vomito negro* (black vomit) derives from the hematemesis often seen in seriously ill cases.

History.—Pre-20th Century.—The pre-Columbian history of yellow fever in the Old and New Worlds is unknown. It is conjectured that the disease was native to Africa and was introduced into the New World. The story of yellow fever in the New World is one of repeated and devastating epidemics among the populations of the seaports of South America, Central America, the West Indies, and the United States through the 17th, 18th, and 19th centuries. During the 18th century, severe epidemics also occurred in Spain and southern Europe. Epidemics in the tropical ports were likely to occur at any season of the year, while epidemics in more northerly ports of the United States, such as New York, Baltimore, and Philadelphia, and in the more southerly ports of Argentina and Chile occurred during the summer season and terminated with the advent of cooler weather. Since it was recognized that cases occurred among passengers and crews of vessels coming from tropical ports, early quarantine services inspected incoming vessels for evidence of yellow fever aboard; when suspicious signs were found, the "yellow jack" (quarantine flag) was raised, forbidding the docking of the vessel or discharge of passengers until danger was deemed to be past. Such measures were in effect decades before the mechanism of the transmission of the disease by mosquitoes was known. In retrospect, the puzzling persistence of the disease on slow sailing vessels is readily understood: the freshwater containers on such ships often bred the vector mosquito. One sick human being aboard a vessel could infect the mosquitoes, which in turn could infect passengers and crew. Ports visited, where infected passengers or infected mosquitoes or both could be discharged, were endangered.

It was also early recognized that in the tropics, even in the absence of recognized cases of yellow fever, the influx of a considerable number of individuals fresh from Europe often resulted in devastating outbreaks of the disease. From this arose the erroneous belief that natives

of a region were not liable to infection but newcomers were.

The early history of yellow fever in Africa is not known. However, attempts during the 19th century to establish trading posts and military garrisons at various points along the west coast of Africa were notably unsuccessful, largely because of yellow fever, malaria, and dysentery, and the region in general became known as "the white man's grave."

Discovery of Transmission Mechanism.—There were many theories about the cause and method of transmission of yellow fever. Carlos Juan Finlay (q.v.) of Havana, Cuba, in the late 19th century maintained that a certain mosquito, *Aedes aegypti*, then known as *Stegomyia fasciata* and ubiquitous in many tropical seaports, was the carrier of the disease. Walter Reed (q.v.) and his associates James Carroll, Aristides Agramonte, and Jesse Lazear, put Finlay's theories to the test and succeeded in 1900 in transmitting yellow fever from one human volunteer to another through the bite of *A. aegypti*. This work was carried out while Reed was a United States Army surgeon stationed in Havana. The group also showed that yellow fever was not transmitted by means of contact, excreta, or soiled clothing and therefore was not contagious.

William Crawford Gorgas (q.v.), another United States Army surgeon, immediately set to work to eliminate *A. aegypti* from Havana. Although his efforts fell far short of eradicating the species, yellow fever speedily disappeared. Oswaldo Cruz similarly cleaned up Rio de Janeiro, Brazil, with parallel results. It is difficult today to realize the excitement with which this conquest of the disease was hailed throughout the West Indies and Central and South America as city after city instituted effective control programs. For over 30 years the opinion prevailed that, if mosquito control programs could be carried out with sufficient rigor, yellow fever would disappear. Some workers had doubts, however, as they noted that cases of yellow fever occasionally occurred in villages where *A. aegypti* was absent and among workers in the forest where, at least in the New World, this mosquito is not found.

Persistence.—In 1933 the occurrence of jungle yellow fever in Brazil and Colombia was first reported. Later workers extended and amplified the picture, showing that there is a cycle of transmission of the disease among New World monkeys by several species of the mosquito genus

Haemagogus. The larvae of these mosquitoes develop in the water that accumulates in tree holes, and the adults spend their lives in the upper canopy levels of the tropical forest. Hunters and woodsmen, working in a region where the disease is current among monkeys, are likely to be bitten by *Haemagogus*, acquire an infection, and sicken in the forest or possibly in a town. In the latter instance, there is grave danger of infecting *A. aegypti* in the town and thus starting an epidemic.

Shaded area shows part of South America where yellow fever is endemic. Visitors are protected by vaccination.

In the forests of equatorial Africa another mosquito, *A. africanus*, has been shown to be a carrier of the disease, maintaining the infection in the forest primates. *A. simpsoni*, which is found more frequently near human settlements than is *A. africanus*, may pick up infection from marauding monkeys from the forest and thus provide a convenient bridge to humans. *A. aegypti* is widespread both in cities and villages and in the forest.

Epidemics of yellow fever are not a thing of the past. In 1933-1938 a massive sweep of the virus was observed in Brazil, originating presumably in the Amazon regions, progressing southward through the country, and reaching the Atlantic coast at Rio de Janeiro. In 1940 a severe epidemic was recorded among the inhabitants of the Nuba Mountains region of the Sudan. In the mid-1950's a massive sweep of infection occurred, progressing northward from Panama through Central America to the southern frontiers of Mexico. In 1954, after an absence of 40 years, there was a small epidemic on the island of Trinidad in the West Indies, and a later small episode occurred there in 1959. In 1961 a massive outbreak was recorded for southwestern Ethiopia. Sporadic cases of the disease are reported frequently from certain countries of the African and New World

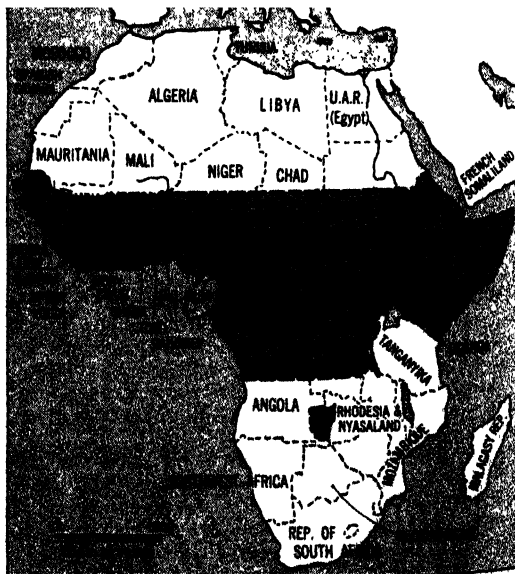

tropics; such occurrences are recorded in the *Weekly Epidemiological Record* distributed by the World Health Organization.

Virus.—Walter Reed showed that the agent of the disease was able to pass a fine filter. Hideyo Noguchi (q.v.), apparently confusing cases of Weil's disease (leptospirosis) with yellow fever, described a causative organism, *Leptospira icteroides*. Later work, however, has established conclusively that the causative agent is a filterable virus, a virus particle having a diameter of 20 millimicrons (0.0000008 inch). By immunological affinities, it is placed in Group B of the arthropod-transmitted viruses, a group which includes such agents as the viruses of dengue, St. Louis encephalitis, and Japanese B encephalitis.

Symptomatology.—A frank attack of yellow fever is characterized by acute onset, with headache, dizziness, rapid rise of fever, backache, nausea, and vomiting. This stage lasts two or three days and may be followed by a brief remission lasting at most a day or two. The more severe cases proceed into stages of deepening intoxication, with high fever, slow pulse, jaundice, albuminuria, and collapse, and death may occur on the sixth or seventh day of illness. However, this classic form of the disease is known to occur in only a small proportion of those infected. Many cases are ill for only a few days, without progression into more serious stages, and many of those afflicted suffer a very mild infection, undiagnosable clinically as yellow fever even during an epidemic when the index of suspicion is high. Recovered cases have no aftereffects but retain a lifelong immunity against later infection. The death rate is difficult to establish; among recognizably ill patients, it may run as high as 50 percent, but in the 1954 outbreak in Trinidad it did not exceed 1 in 1,000 of those infected. No specific treatment exists. Supportive therapeutic measures are indicated, and absolute rest is advisable during the acute phase.

Diagnosis.—During an outbreak, a severe case of yellow fever is not likely to go unrecognized.

Endemic area of Africa (shading). Mosquito control helps protect cities but is impracticable in forest areas.

However, the sporadically occurring severe case or the severe case occurring early in a developing outbreak may well be confused with other diseases. Milder cases may easily be mistaken for other mild fevers. Consequently, the laboratory offers the only certain means of diagnosis. Positive diagnosis is effected by the isolation of the virus from the blood stream during the early stage of the disease (virus has been isolated as late as 11 days after onset) or from the liver of fatal cases. The serum or liver suspension is inoculated subcutaneously into monkeys or intracerebrally into white mice, which are then observed for signs of illness. Microscopic examination of liver tissue of fatal cases may reveal characteristic pathological changes indicative of the disease.

Positive diagnosis can also be made by the protection or neutralization test, carried out in white mice or in an appropriate tissue culture. Scrums from a blood sample taken early in the disease and from another sample taken 10 days or more later are compared by mixing each with a known amount of yellow fever virus and inoculating into the mice or culture. If there is a marked difference in the degree of protection (neutralization of virus by immune substance or antibody) afforded by the second specimen, a diagnosis of yellow fever is warranted. Special immunological reactions may also be useful. Complement-fixing antibodies and antibodies inhibiting the agglutination of chicken or goose erythrocytes by yellow fever virus develop during the course of the disease and can be measured by appropriate tests. Cross-reaction with other related Group B viruses complicates the interpretation of the complement-fixation and hemagglutination-inhibition tests, and considerable experience is needed in their interpretation.

Prevention and Control.—The vector mosquito, *A. aegypti*, has been eradicated from many countries of the New World, and the World Health Organization is continuing with a program of eradication for the rest of the Western Hemisphere. The problem of jungle yellow fever in the New World tropics still remains. In Africa, *A. aegypti* control affords some measure of protection in towns and cities, but mosquito control measures are not practicable for the forested areas.

Vaccination is the recommended procedure for populations likely to be in contact with yellow fever. Over 95 percent of those vaccinated develop demonstrable immunity, which appears in 10 days to 2 weeks and persists for longer than 6 years. The 17D strain of vaccine developed by Max Theiler through repeated passage of a virulent strain of virus in tissue culture is routinely employed. In the course of passage, the virulence of the original strain is lost. The derived (17D) strain, inoculated subcutaneously into humans, produces a very mild infection with few or no symptoms and imparts a long-lasting immunity against the virulent virus. The vaccine is prepared in embryonated chicken eggs. A second type of vaccine, known as the French neurotropic strain, modified in virulence by brain-to-brain passage in white mice, is extensively used by the French in Africa and is administered by scarification.

International control has two responsibilities. Individuals entering regions where yellow fever is endemic (see accompanying maps) can easily be protected by requiring vaccination; however, many countries where yellow fever is known or suspected to be endemic do not require vaccination. A second grave responsibility is the protec-

tion of areas where yellow fever does not occur but *A. aegypti* flourishes, as in Southeast Asia and the East Indies, including India, and the countries of the Mediterranean area. Introduction of the virus by means of a human carrier or an infected mosquito constitutes a continuing threat in these areas. Regulations requiring evidence of yellow fever vaccination of individuals entering such areas from known endemic areas and for spraying aircraft with insecticides before landing are now generally, although not uniformly, in force.

International Sanitary Regulations provides current information on endemic areas, requirements for vaccination and revaccination, and control of international travel.

YELLOW JOURNALISM, a term synonymous with "sensationalism," used in the sense that a newspaper or periodical deliberately undertakes to capture reader attention and interest by a contrived emotional appeal basically unwarranted by fact or subject matter. The methods employed are the selection or creation of subject material lending itself to this purpose; the use of appropriate styles of writing, typographical displays, and illustrations; and general promotional publicity.

Although there had previously been sensationalism of some sort or degree in more than one country and over a long period of time, the use of the term "yellow journalism" derives from practices by two New York City newspapers during the latter half of the 1890's. The *New York World* had presented what purported to be humorous drawings since 1889, the beginning of comic strip usage. In 1893 the *World* became a pioneer among newspapers in the use of color. In February 1896 it used its color press to add a yellow tint to a shapeless sacklike garment worn by a gap-toothed young ragamuffin, the central figure in a series of drawings by Richard F. Outcault, portraying fanciful incidents in a city tenement district. This was a novelty, and "the yellow kid of Hogan's Alley," as the youngster came to be known popularly, helped to bring new circulation to the paper.

In 1895 William Randolph Hearst, after developing the San Francisco *Examiner* as his first newspaper, had purchased the *New York Journal* and entered into direct competition with the *World* for morning newspaper circulation leadership. Observing the popularity of Outcault's drawings, Hearst offered him financial inducements to produce the "yellow kid" for the

Journal's Sunday color supplement. This he began to do in October 1896. The *World* countered by engaging George B. Luks to continue the "yellow kid" in that paper. The rival "yellow kids" were widely publicized throughout the New York area on posters and on the sides of circulation wagons.

At the same time, the *Journal* and the *World* were competing for readers by other means, such as seeking news and even creating news that could be written and presented to arouse the greatest emotional response among prospective readers, including buyers at the newsstands and in the streets. This practice involved an emphasis on crime, sex, and violence. It exploited especially the then current revolt of the Cubans against Spanish rule, which led directly to the Spanish-American War in 1898. It involved a resort to typographical extravagances beyond any previously known, including the use of large headlines, some occupying half of the first page or more, frequently printed in lurid colors, and often conveying distorted impressions. This was supported by no less distorted writing and by illustrations specially drawn to create the desired impact. The result was to win for both newspapers the largest circulations so far known anywhere on earth, sometimes exceeding a million copies a day.

The excesses to which the papers went, however, offended and outraged many thoughtful citizens and dismayed competing papers in New York. Ervin Wardman, editor of the *New York Press*, associated the two manifestations—sensationalism and rival promotion of the "yellow kids"—in a blanket reference to the "yellow press" of New York, from which the use of the term "yellow journalism" in the broader sense evolved.

YELLOW PUCCON. See YELLOWROOT.

YELLOW RATTLE, the common name of several species of plants belonging to the genus *Rhinanthus* (called *Alectorolophus* by some botanists), of the figwort family Scrophulariaceae. The generic name, from Greek *rhis* (snout) and *anthos* (flower), refers to the beaked upper corolla lip of a species no longer included by botanists in the genus *Rhinanthus*. The sessile flowers (usually yellow) are borne in the axils of the uppermost bracts of the stems, which bear opposite leaves. The individual flowers have four sepals, which become inflated in fruit; five two-lipped petals with a hooded upper lip and a three-lobed lower one; four stamens; and a loculicidal orbicular capsule containing round-winged seeds, which rattle in the fruit when it is shaken. The plants are root parasites, attaching themselves to various species of plants, and sometimes become pests in the fields of Europe.

The genus *Rhinanthus* is most common in the Arctic and cold temperate zones of the Northern Hemisphere, occurring in Asia, Europe, and North America. The most common species in North America is *R. crista-galli*, which grows from Labrador to Alaska and British Columbia and south to southern New England and northern New York State. The name "rattlebox," sometimes confused with yellow rattle, should be

applied only to species of the genus *Crotalaria*.
DAVID E. FAIRBROTHERS.

YELLOW RIVER. See HWANG HO.

YELLOW-ROOT. See YELLOWROOT.

YELLOW SEA (Chin. HWANG HAI or HUANG HAI), one of the extreme western outliers of the Pacific Ocean bordering the coastlines of Shantung and Kiangsu provinces, China, and situated north of the East China Sea between the China mainland and the Korean Peninsula. Approximately 400 miles long and 400 miles wide, the Yellow Sea is connected with the gulfs of Chihli (Po Hai) and Liaotung to the north by the Strait of Chihli, which separates the Liaotung and Shantung peninsulas.

Among the major rivers flowing into the Yellow Sea are the Yellow, Hwai, Liao, Pai, and Yalu rivers of China, and the Korean Han and Taedong rivers. Major ports along the Yellow Sea and Gulf of Chihli include Lienyün, Tsingtao, Yentai (Chefoo), Tangku (Sinkang), Chinnwangtao, Hulutao, Port Arthur (Lüshun), Talien (Dairen), and Sinkin (Hsinchin, Chengtsetuan) in China; Inchon in South Korea; and Chinnampo in North Korea.

BARUCH BOXER

YELLOW-WOOD. See YELLOWWOOD.

YELLOWHAMMER, yē'ō-hām-ər (also called **YELLOW BUNTING**), a familiar songbird (*Emberiza citrinella*) of Europe. The yellowhammer is about 6½ inches long and is a typical bunting with a streaked plumage. The ground color is yellow below and brownish above, and the male has a distinctive yellow head. The yellowhammer inhabits bushes in grasslands or open areas and has a tinkly song. The breeding range extends eastward from Europe to Iran and central Siberia; the bird tends to be resident (nonmigratory) throughout its range.

CHARLES VAURIE.

YELLOWKNIFE, yē'ō-nīf, a town in the Northwest Territories, Canada, in Fort Smith Region, 600 miles (970 km) north of Edmonton and 280 miles (450 km) south of the Arctic Circle, on the west shore of Yellowknife Bay, a broadening of the Yellowknife River where it flows into Great Slave Lake. The name is derived from the Yellowknife Indians, an Athapascan tribe living to the north of Great Slave Lake and given the name Yellowknife because they used tools of native copper. The settlement began with the discovery of rich gold ore deposits near Yellowknife Bay in 1934 and 1935. Another gold strike in 1944 led to a second period of expansion, and as the original townsites became too cramped, a new town was built on a different site. It is now the largest center in the Northwest Territories. Two producing gold mines support most of Yellowknife's population, but it is also the center for another gold mine 60 miles to the north and for the development of mineral properties throughout the surrounding region. There is daily air service to Edmonton, and the Great Slave Highway, opened in 1961, makes it possible to drive to Yellowknife from southern Canada. It became a municipal district in 1952 and was incorporated as a town in 1963. Population: 9,483.

GRAHAM W. ROWLEY.

YELLOWLEGS, yel'ô-lëgz, the common name of two large North American shorebirds of the genus *Totanus*. The greater yellowlegs (*T. melanoleucus*) is about 14 inches long and breeds in the muskeg country of the northern forests from southern Alaska, southern Mackenzie District, and the Ungava Peninsula, Canada, south to central British Columbia, central Alberta, James Bay, southeastern Quebec, and Newfoundland. The lesser yellowlegs (*T. flavipes*) is about 4 inches smaller and has a somewhat similar breeding range which, however, extends a little farther north to the forested tundra. It also prefers drier sites as a rule and is especially attracted to areas that have been recently burned over. The two birds are identical in appearance, except for the marked difference in size. They are ashy or brownish gray above, mottled with white, and white below speckled with gray, and have bright yellow legs. Their loud, clear calls are rather similar, but those of the greater yellowlegs are uttered in groups of 3 or 4 notes, as against 1 or 2 for the lesser yellowlegs. The birds nest on the ground, laying 4 eggs that are heavily marked with brown, in a shallow scrape or natural depression.

Allan D. Cruikshank, from National Audubon Society

Greater Yellowlegs (*Totanus melanoleucus*)

The period of incubation lasts for about 3 weeks. Their food consists of insects or small aquatic animals. Both species are highly migratory and winter from the southern United States to the tip of South America. On migration and on their winter grounds they frequent the grassy margins of pools, lakes, and the mud flats along the sea.

CHARLES VAURIE
American Museum of Natural History

YELLOWROOT, yel'ô-rôot, the common name of three berberine-containing plants in the buttercup family (Ranunculaceae). *Xanthorhiza simplicissima*, shrub yellowroot, grows in the southeastern United States. The interior of its roots and stems is bright yellow and astringent and has been used in tonic bitters. It is about two feet tall, and its leaves give it a fernlike appearance. *Coptis groenlandica*, often called goldthread, is a tiny, slender shrub recognized by its shiny evergreen three-parted leaves. It occurs in cool woods, ranging northward from the mountains of North Carolina. The brilliant yellow, bitter stems and roots have been used in local applications for ulcers of the mouth. *Hydrastis canadensis*, sometimes called

orangeroot, goldenseal, or yellow puccoon, is an herb with a single basal and two stem leaves with reniform, palmately lobed blades. It occurs in deciduous forests from Nebraska and Arkansas eastward. Highly valued for use in drugs for catarrh and inflammation of the gastrointestinal tract and other mucous membranes, it has been almost exterminated by herb gatherers. The Indians prized the rootstock as a source of yellow dye.

A. J. SHARP
University of Tennessee

YELLOW S VIRUSES, yel'ôz vî-ras-az, plant-pathogenic viruses that cause diseases of the plant subclasses Dicotyledoneae and Monocotyledoneae. The diseases, called yellows, are characterized by chlorosis without spotting, by stunting, and by adventitious shoots with long or short internodes. Examples are aster yellows, peach yellows, and corn stunt. So far as is known, all insect vectors of yellows viruses belong to leafhoppers of the family Cicadellidae. These carriers show a high degree of specificity, so that transmission of each virus is limited to a small number of insect species, often closely related. The specificity may be so extreme that different strains of a single virus are transmitted by different species of leafhoppers. In some instances, where several virus strains are transmitted by the same vector species, a process of interference occurs in the insect so that all are excluded except the virus strain first acquired. It has been difficult or impossible to transmit most yellows viruses mechanically to plants, except through grafting. Grafting through a "bridge," by means of plant-parasitic species of *Cuscuta* (dodder), permits the transmission of infection from plant to plant for the purpose of laboratory study. *Vinca rosea* (periwinkle), susceptible to most yellows viruses, has become a preferred experimental host for both the study and storage of yellows viruses.

All yellows viruses of this group are retained in the insect vectors, and all have long incubation periods in both plants and leafhoppers. Several yellows viruses multiply not only in diseased plants but also inside their vectors. For this reason the yellows viruses can be considered as both plant and insect viruses. In spite of their worldwide distribution, very few yellows viruses have been characterized morphologically. Control of the diseases in plants is difficult because field applications of insecticides seldom destroy all vectors and the few remaining survivors continue to infect plants. Complete control can be achieved by screening to prevent the access of infected leafhoppers to the plants so protected.

YELLOWSTONE LAKE, yel'ô-stôn, lake, Wyoming, in Yellowstone National Park, at an elevation of 7,731 feet, with a maximum depth of 300 feet and an area of 139 square miles. Its remarkable size is due to the gently sloping surface of the lava plateau, further smoothed by glaciation. The lake measures 21 miles in length from the outlet at the north to the south end of the south-east arm and is fed and drained by the Yellowstone River (q.v.). It is extremely popular as a fishing lake. West Thumb Geyser Basin lies at the end of the western arm, and the thermal activity actually extends out into the water.

GEORG GERSTER, FROM PHOTO RESEARCHER

Old Faithful geyser in Yellowstone National Park is noted for the regularity and height of its eruptions.

YELLOWSTONE NATIONAL PARK, a national park in Wyoming, Montana, and Idaho, with most of its area in Wyoming. It is the largest and oldest unit in the national park system of the United States. A plateau area within the Rocky Mountains, shaped approximately in a square with 60 miles to a side, the park has an area of about 3,472 square miles. Geysers, which occur in very few other places in the world, occur here in profusion, along with hot springs, steam vents, and associated phenomena. The park is administered by the National Park Service, and park headquarters are located at Mammoth, Wyo.

Natural Scene. During the last 50 million years the park plateau has been built up of hundreds, possibly thousands, of feet of lava and breccia. This plateau is rimmed by four mountain ranges. The Gallatin Range extends through much of the western side of the park; the Beartooth Range dominates the northern margin. The crest of the Absaroka Range constitutes the eastern boundary and provides a rugged skyline when seen from the lower general surface of the plateau. The southern margin is formed by the highlands of the Jackson Hole country including the Teton Range, the major feature of an adjacent but independent national park (Grand Teton). The general elevation of the Yellowstone region is from 7,000 to 8,000 feet; among the highest mountains are Electric Peak (10,992 feet) and Eagle Park (11,358 feet).

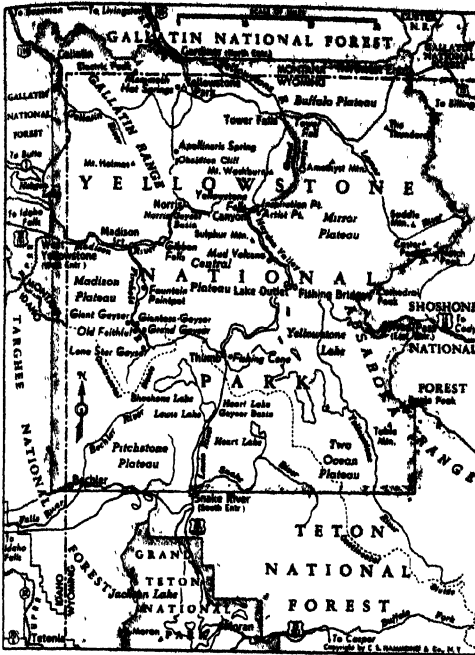

Most of the park is drained by the Yellowstone River, a major tributary of the Missouri-Mississippi river system. Portions of the western side drain into the Madison and Gallatin rivers, which are also Missouri tributaries. Part of the south side of the park is on the Pacific

slope of the Continental Divide draining through the Snake River into the Columbia River.

The most spectacular scenery of the region is carved into the plateau surface by the Yellowstone River. Between the Upper Falls, Lower Falls, and Tower Junction, the Yellowstone has cut one of the great canyons of North America, over 1,000 feet deep and 24 miles long. Early hydrothermal activity weakened the rock and colored it shades of yellow, orange, and red, as well as buff and gray. The canyon is steep-walled with no flat floor; there is only room for the turbulent, bright green river itself at the bottom. Pinnacles and spires stand up from the steep sides. At the southern end of the river, the Upper Falls have a drop of 109 feet, and the Lower Falls a drop of 308 feet.

Geysers and Hot Springs. For most visitors the features of central interest in the park are the geysers and hot springs. These are related to the geologically recent volcanic action in the region, as a result of which water from the surface encounters unusually hot rock within a few hundred feet of the surface. Heated, and in some cases turned into steam, this water returns to the surface, causing the unusual thermal phenomena. During the water's movement, minerals are picked up, and some are deposited near and on the surface. This material is responsible both for the unusual surface forms and also for the contorted subsurface caverns which allow the geysers to develop.

In one area, Mammoth Hot Springs, the mineral in solution is calcium carbonate. The hot water, upon cooling at the surface, precipitates some of the mineral as travertine, making broad terraces. In other regions the hot water

Location and features of Yellowstone National Park.

has a suspension of colloidal silica. With changes in temperature and pressure, and with evaporation, the silica forms a solid called geyserite, a member of the opal family of minerals. This is the material of which the geyser cones and sinter are composed.

In the hot springs the suspension of silica is given credit for one of the special visual effects of the water, a quality of opalescence. Most of the color effects, however, are caused by algae which grow year round in the warm water. Each type of algae is specific to water at a given temperature, and consequently a wide range of blue, green, yellow, orange, and brown colors may occur within a few feet as the water cools.

Most of the geyser activity takes place in saucer-shaped depressions in the lava surface, hence the designation "geyser basins." Upper Geyser Basin, containing Old Faithful, and three adjacent basins immediately to the north (Biscuit, Midway, and Lower Geyser basins) draw the greatest interest. Also on the highway and frequently visited are Norris and West Thumb Geyser basins, and the Dragon's Mouth area in the Hayden Valley. Approximately 200 geysers have been observed and named, though only those in the basins along the road are well known. A great variety may be observed, from towering eruptions of steam to small spurts.

The most famous by far is Old Faithful, unusual both for the regularity of its cycle and the height of its eruption. The cycle rarely takes more than 80 minutes or less than 40; it averages just over 60 minutes. Its eruption is of impressive size and forcefulness, shooting hot water over 100 feet and sometimes almost 200 feet in the air.

Geological Features and Wildlife. In two areas of the park there are fossil forests, areas of abundant petrified tree trunks and also many fossil leaves. Yellowstone Lake to the south is an unusually

large lake for such a high elevation (7,731 feet above sea level). Glaciers, which covered the whole plateau at one time, have left their marks in scoured bedrock and in glacial till and erratics.

Wildlife rivals geology as an object of interest in the park. Fishing is permitted and is very popular in the lakes and streams; trout are taken most often, but some grayling are also caught. Hunting is not permitted, and some wild species may be observed at close range. Antelope, deer, elk, buffalo, coyotes, bear, and several species of waterfowl are often seen. Elk (wapiti) have increased beyond the capacity of the range to support them. With the timber wolf exterminated and the mountain lion almost so, there is no natural check on the elk population short of starvation. Severe control measures, including limited hunting, have had to be taken in some years.

History. It was early thought that the park region had been avoided by American Indians. Most of the nearby tribes were superstitious about the hydrothermal activity. But there is increasing evidence of Indian occupancy. One group, the Sheepeaters, lived in the park. Others crossed it regularly and came to secure obsidian for arrowheads and other tools.

The official history of Yellowstone National Park began in 1870 with the Langford-Washburn-Doane expedition. Earlier, "mountain men" had returned from the region with "fantastic" tales that were dismissed as fabrications. In 1870, Nathaniel P. Langford and Henry D. Washburn gathered a small group together to inspect the area and set the record straight. They were joined by Lt. Gustavus Doane of Fort Ellis and a small group of infantry. Needless to say, they found magnificent natural phenomena.

While they were at their last camp in the area, the idea was put forth that this region was too important to divide up for private gain and should instead be set aside for public use. This was the first significant proposal countering the prevailing philosophy that the public domain should be sold or given away in its entirety. During the next two years, with considerable promotion by Langford, the idea caught hold, and on March 1, 1872, by an act of Congress, the Yellowstone National Park area was withdrawn from private entry. In 1886 administration of the park was given to the Army, passing to the National Park Service after the latter was created in 1916.

In the summer of 1988, unprecedented weather conditions and other factors combined to intensify the severity of eight fires—some naturally ignited and some caused by human negligence—that eventually burned over about 1.4 million acres in and around the park. It was estimated that 1,400 acres were burned severely enough to leave them barren. Wildlife in the park was affected less by the fires themselves than by the loss of winter forage. The fires raised complex questions about park service fire-management policy.

YELLOWSTONE RIVER, river, Montana and Wyoming, a major tributary of the Missouri River, 671 miles long. It rises in the Absaroka

Range in northern Wyoming and flows northward through Yellowstone National Park into southern Montana, where it turns to flow north-eastward to its junction with the Missouri in westernmost North Dakota. Its headwaters are in high mountain wilderness. Within Yellowstone National Park, it creates Yellowstone Lake, one of the largest lakes to be found at so high an elevation. Its canyon, just north of the lake, is one of the great scenic features of the park. Until it reaches Gardiner, Mont., the river's course is so rugged that transportation routes do not follow it, but from Gardiner on to its confluence with the Missouri, it is paralleled by railroads and major highways. Most of the land in the valley floor is irrigated from the river, some of this in large federal irrigation projects. Practically all of the river's tributaries come from the south, such as the Stillwater, Clark Fork, Bighorn, Tongue, and Power rivers.

YELLOWTAIL, a marine fish—a species of jack, *Seriola dorsalis*—widely distributed in warm waters of the Pacific Ocean. The species is also known as Pacific yellowtail, and California yellowtail, and in the New Zealand–Australia region as the yellowtail kingfish. It is a popular sport fish along the coast of southern California and Mexico, and it is also important commercially. It has a bright yellowish bronze band from snout to tail, yellowish fins, and a yellow tail.

The name "yellowtail" is sometimes given to an unrelated species, the Atlantic snapper, *Ocyurus chrysurus*.

YELLOWWOOD, a name applied to several trees and shrubs, including *Cladrastis lutea*, a small tree of the Leguminosae, or legume family. Rare and local in occurrence, it is found in the mixed hardwood forests of Tennessee, Kentucky, and southern Missouri, although its complete geographical range includes western North Carolina, southern Indiana, southern Illinois, northern Georgia, northern Alabama, central Arkansas, and northeastern Oklahoma. Under optimum conditions for growth, the tree may attain a height of 60 feet (18 meters) and a diameter of 24 inches (46 cm) or more. Yellowwood is identified by its smooth, silvery gray-brown bark; alternate, deciduous, pinnately compound leaves, each with 5 to 11 leaflets; long chains of white, locustlike, fragrant flowers, each with a bright red ovary; small, linear, 4- to 6-seeded podlike fruits; and winter twigs of varnished appearance.

Yellowwood is not important to the timber economy of the United States. The hard, bright gold wood has been used locally for the production of gunstocks and for fuel and at one time was a commercial source of a yellow dye principle. The species is drought resistant and is quite hardy far north of its natural range. Open-grown trees develop pleasingly symmetrical crowns that, when in full flower, are of great beauty. Called "virgilia" by horticulturists, yellowwood is used as an ornamental but should not be used in regions where sleet storms are common, as its limbs are brittle. The species is easily grown from seed and may be propagated from fall root cuttings stored in cool, moist soil during the winter.

E. S. HARRAR, *Duke University*

YELTSIN, yel'tsén, Boris Nikolayevich (1931–), Soviet political leader. He was born on Feb. 1, 1931, in Sverdlovsk province. A civil engineer, he joined the Communist party in 1961 and came to national attention with his 1976 appointment as first secretary of the Sverdlovsk regional party committee, which carried with it membership in the all-Union Central Committee in Moscow. He became known for his executive ability and for having the courage of his convictions. Named head of the Moscow party organization by Mikhail Gorbachev in 1985, Yeltsin was soon elevated to the Politburo. However, his aparty career ended abruptly, late in 1987, when he attacked the slow pace of reform under Gorbachev. Stripped of his posts, he was relegated to a ministerial job, but in semi-free, all-Union parliamentary elections early in 1989, he won a seat from Moscow by a landslide.

In March 1990, Yeltsin won an easy victory in the parliamentary election of the Russian republic. In May, despite opposition orchestrated by Gorbachev, he was elected president of the Russian republic by its legislature. He was quickly recognized as the most popular political figure with the Soviet public, eclipsing Gorbachev. In July, Yeltsin stunned the country by resigning from the Communist party at its Congress. He set up a young, pro-reform government in the Russian republic and led its declaration of sovereignty. Open challenges to Gorbachev followed—on Lithuanian independence, and over control of banking and natural resources in the Russian republic. In late summer, Yeltsin drew enthusiastic crowds as he began his huge, campaign for the first direct, popular election of the republic's president, which he won in 1991. His message was on the need to confederate the USSR, privatize property, and rapidly "marketize" the economy. Thanks largely to Yeltsin's efforts, a hard-liner coup against Gorbachev failed in August 1991. As a result, Yeltsin became de facto co-leader of the USSR with Gorbachev.

ROBERT SHARLET, *Union College*

YEMEN, People's Democratic Republic of, yem'an, a former country on the southern coast of the Arabian Peninsula. Known as Southern Yemen until 1970 and sometimes referred to as Yemen (Aden), it consisted of the city of Aden and its surroundings and the former British Protectorate of South Arabia (earlier called the Aden Protectorate). It ran along the coast of Arabia for some 700 miles (1,100 km) and in places reached about 200 miles (320 km) inland. The islands of Perim (at the mouth of the Red Sea), Kamaran (off the coast of the Yemen Arab Republic), and Socotra (some 200 miles, or 320 km, off the southern coast) also belonged to the republic.

Because of a disputed border with Saudi Arabia, estimates of the country's size varied. One frequently cited figure was 128,560 square miles (332,968 sq km). The capital of the country was the port city of Aden. The sandy coast was arid. The land farther inland became mountainous and was crossed by wadis, or riverbeds that filled with water only after a rain. The northeast was desert. The climate was extremely hot, and rainfall was less than 3 inches (76 mm) annually.

The population of the country was recorded at 2,345,266 in the 1988 census. The majority lived along the coast. The language of the country was Arabic, the religion Muslim. The people were primarily farmers and nomadic herders.

CLAUDE SALHANI/SYGMA

Ancient Sana, capital of the Yemen Arab Republic, became the capital of a united Yemen in 1990.

The subsistence crops raised included sorghum, sesame, millet, wheat, barley, and dates. The chief cash crop was long-staple cotton. Oil had been discovered, and there was an oil refinery in Aden. The country's exports included petroleum products, cotton, hides and skins, coffee, and dried fish.

Prior to the closing of the Suez Canal in 1967 during the Arab-Israeli War, Aden was one of the world's busiest bunkering ports. It was the chief port of call for traffic between Europe and the Indian Ocean and the Far East. Its importance was greatly diminished by the closing of the canal. The port fell into disrepair, and this important source of foreign currency dried up. Aden did not fully recover after the reopening of the canal in 1975.

History. In ancient times, Aden was a port for the incense and spice trade between East and West. The area came under the sway of Islam in the 7th century A.D. For a time it formed part of the Ottoman Empire. In 1839 the British seized Aden, to guard the route to India. Gradually the British extended their control inland and eastward. Ultimately the British protectorate included more than 20 sultanates, emirates, and sheikhdoms.

Under British sponsorship, several states in the Protectorate of South Arabia formed a federation in 1959; three years later it became the Federation of South Arabia. In 1963, Aden adhered to the federation, but the large sultanates in the eastern part of the protectorate, called the Hadhramaut, refused to join.

In 1967 the National Liberation Front (NLF) undermined the federation and overthrew many

of the rulers in the protectorate. Independence came on Nov. 30, 1967, and the head of the NLF, Qahtan al-Shaabi, was elected president.

On June 22, 1969, Qahtan al-Shaabi was deposed in a bloodless coup by a group of young leftists. It was to be the first of several coups in the years to come, reflecting the political instability of the country.

Chronic border warfare with the Yemen Arab Republic alternated with discussions about possible unification. Even though that country held Democratic Yemen responsible for the assassination of its president in June 1978, unification talks were resumed less than a year later. Democratic Yemen's successive Marxist governments maintained close ties with the Soviet Union, from which it received substantial aid and to which it granted military prerogatives on its soil. On May 22, 1990, the two Yemens united to form the Yemeni Republic. See also YEMENI REPUBLIC.

YEMEN ARAB REPUBLIC, a former country situated in the southwestern corner of the Arabian Peninsula. It was bounded on the north by Saudi Arabia, on the east and south by the People's Democratic Republic of Yemen, and on the west by the Red Sea. In dispute was much of its northern and eastern boundary. The area of the Yemen Arab Republic was estimated at 75,290 square miles (195,000 sq km) and its population (1986 census) was 9,274,173.

Physical Features. The land consisted of a narrow coastal strip and an extensive hinterland of broken highlands. The coastal lowland, the Ti-hama, extended 20 to 30 miles (30–50 km) inland from the Red Sea. It was humid, hot, and sterile, with a few scattered oases. The highlands rose to an elevation of 12,336 feet (3,760 meters). Rainfall varied from 15 to 30 inches (400–800 mm) annually. Summers on the highlands were relatively temperate, and winters were cool, giving the area the best climate of the entire Arabian Peninsula. Sana, the official capital, was situated on a plateau more than 7,000 feet (2,130 meters) above sea level. Taiz, the former royal residence, had an elevation of 4,500 feet (1,370 meters). The two principal seaports were Hodeida and Mocha.

The People. Unlike other Arabians, the Yemenis were settled, and there were hardly any nomads. They also differed in being mostly Shiites of the Zaidi variety, a moderately dissident Muslim sect that comes closest to the majority Sunnites. Most of the lowlanders are Sunnites of the Shafi rite. Some 50,000 Jews, mainly from Sana, emigrated to Israel shortly after it won independence in 1948. Roughly, the people consisted of (1) aristocrats (sayyids, lords), who were descended from the Prophet Mohammed and were considered custodians of the Muslim religion; (2) tribespeople, mostly in the highlands; and (3) a mixed population along the coast with a strong African element. Literacy was low, about 15%. Education followed the traditional model, centering in mosques or mosque schools. A modern graded school system was introduced after World War II and was conducted largely by Egyptian and Palestinian teachers.

Economy. Agriculture in the highlands and trade along the coast were the chief occupations of the people. The land contained some of the most fertile areas of the Arabian Peninsula, its terraced slopes, receiving enough rain to make cultivation possible. Sorghum, millet, wheat,

barley, and maize (corn) were grown in the highlands, as well as potatoes, tomatoes, grapes, apricots, and peaches. Two major crops of this area were coffee, once the country's chief source of foreign exchange, and khat (*qat*), a popular narcotic stimulant consumed by chewing the leaves or drinking a brew made from them. As farmers discovered that khat for the domestic market yielded the more reliable profits, they diverted to it much land from coffee for export. Cotton, tobacco, and dates were grown in the lowland. Mineral production included petroleum and salt. Among the handicraft industries were leatherworking and sword making; in the modern manufacturing sector were oil refining and cotton textile weaving. Before the 1960's, transportation depended largely on pack animals. Afterward the road system was improved, permitting motor vehicle traffic between main towns.

Government. Until September 1962 the government of Yemen was an absolute monarchy with patriarchal features; the law was that of the Koran. Yemen was one of the few Muslim lands that had not been opened to modernizing influences. The imam Ahmad ibn-Yahya (reigned 1948–1962) was head of the Zaidi sect and temporal and spiritual leader of all the people. Uprisings aimed at reform were all suppressed. Following an unsuccessful coup in which a brother of the king was involved, Ahmad in 1956 initiated a council of state (cabinet), in which his son Crown Prince Saif al-Islam Muhammad al-Badr became minister of foreign affairs and minister of defense. The imam himself held the premiership. Under the republic established in 1962, the army dominated the government. However, a military council gave way in 1978 to a popular assembly, which afterward elected a president with executive powers.

History. Yemen, a part of classical Arabia Felix, was the earliest seat of Arabian culture, dating from the early part of the first millennium before Christ. It saw the rise and fall of three major peoples, the Minaeans, Sabaeans, and Himyarites. Its prosperity was due to the cultivation of spices, frankincense, and other semitropical products in demand around the eastern Mediterranean basin. With the rise of Islam the country formed a part of the caliphate, and later of certain successor states of the caliphate. In 1517, following the destruction of the Mamluk Empire by the Ottoman Turks, Yemen was occupied by the Ottomans.

The modern kingdom of Yemen had its inception in 1904, when Imam Yahya Hamid al-Din revolted against the Ottomans, but it did not achieve full independence until 1918, at the end of World War I. Yahya's conflict with King Abdul-Aziz ibn-Saud was resolved in 1934, when the disputed area of Asir was officially lost to Saudi Arabia. After that, Yahya styled himself king. He was murdered in 1948 and succeeded by his eldest son, Ahmad. Under him, Yemen's claim to sovereignty over Aden and the Aden Protectorate was repeatedly pressed, resulting in clashes with the British. In 1945, Yemen joined the League of Arab States and two years later the United Nations, and in 1958 it established a loose federation with the new United Arab Republic. After Syria's secession from the republic in September 1961, Yemen's tie was also broken. Technical aid had been provided by the West as well as by the Soviet Union and Communist China.

On Sept. 27, 1962, only a few days after the accession of al-Badr to the throne vacated by the death of his father, Ahmad, a military coup overthrew the monarchy and a republic was proclaimed. The leader was Abdullah al-Salal, who became president of the republic and received substantial aid from Egypt. Royalists, faithful Zaidis, and tribesmen rallied to the king's support, with Saudi Arabian backing. In 1967, Egyptian troops in Yemen at Salal's request were withdrawn because of war with Israel, and he was deposed by other republican leaders. By 1970, after withstanding a royalist siege of the capital, the government had reached an accommodation with most royalist groups and the Saudis. However, the country remained unstable until after Lt. Col. Ali Abdullah Saleh came to power in 1978.

The Yemen Arab Republic (YAR) and the People's Democratic Republic of Yemen engaged in intermittent border warfare while nonetheless exploring the possibility of their unification. Saleh obtained military and other aid from the USSR, but also from the United States. The economy, dependent on Saudi assistance and on receipts from Yemenis working in Arab oil-producing countries, was adversely affected by the downturn in world oil prices. Paradoxically, it was bolstered by the subsequent discovery of oil in the YAR itself. On May 22, 1990, the two Yemens finally united, forming the Yemeni Republic. See YEMENI REPUBLIC.

PHILIP K. HITTI*

Author of "The Middle East in History"

YEMENI REPUBLIC, yem'-ə-nē, a country in the southwestern part of the Arabian Peninsula. It was formed on May 22, 1990, by the merger of the Yemen Arab Republic (North Yemen) and the People's Republic of Yemen (South Yemen). The country has an area of approximately 203,850 square miles (527,968 km) and a population (1990) of about 13 million. The capital is Sana; the economic center is the port of Aden.

Unity was achieved despite fundamental differences in the government of each country. North Yemen, the more populous, was dominated by the traditions of tribe and Islam, whereas South Yemen had a Marxist government that promoted modernism and secularism. South Yemen, however, had eased its commitment to Marxist principles before the merger.

President Ali Abdullah Saleh of North Yemen was elected president of the Yemeni Republic by the parliaments of both countries. The legislatures chose Ali Salem al-Baidh, secretary-general of the ruling Socialist Party of South Yemen, as vice president. A five-member governing council contained, besides the president and vice president, one southerner and two northerners. In a referendum boycotted by Islamist groups, a constitution was approved in May 1991.

The government hoped to increase the production and export of oil, found in both Yemens in the 1980s. For favoring Iraq in the Persian Gulf crisis and war (1990–1991), the Yemeni Republic had 1 million of its guest workers expelled from Saudi Arabia. YENBO. See YANBU.

YENISEI RIVER, yen-ə-sā', in the Russian republic of the USSR. One of the longest rivers in the Soviet Union, it forms in effect the boundary between the West Siberian lowland and the Central Siberian uplands. Although the Yenisei system has a total length of about 2,500 miles (4,000 km), the river proper commences at the confluence of the Bolshoi Yenisei and the Maly Yenisei rivers, near Kyzyl in the Tuva ASSR, and flows generally north for over 2,000 miles (3,200 km) into Yenisei Gulf in the Kara Sea, an arm of the Arctic Ocean. Its basin occupies an area of over 1 million square miles (2.6 million sq km).

The upper Yenisei, from Kyzyl to Abakan, is shallow and full of rapids. The middle course, from Abakan to the mouth of the Angara below Krasnoyarsk, widens to 9 miles (14 km) and deepens to 30 feet (9 meters). The lower Yenisei, from the Angara River to Yenisei Gulf (over 1,200 miles, or 1,900 km), is from 6 to 25 miles (10–40 km) wide and, below Turukhansk, from 45 to 75 feet (14–23 meters) deep with a current of only 1.8 to 2.5 miles (2.9–4 km) an hour. In its lower course, the Yenisei is strengthened by three turbulent, right-bank tributaries: the Angara (Upper Tunguska), which drains Lake Baikal; the Middle Tunguska; and the Lower Tunguska.

Because of the severe Siberian climate, the upper Yenisei is frozen from mid-November to the end of April; the lower Yenisei, from October to the beginning of June. The abrupt onset of spring in the south causes rapid melting of the snow and a sharp rise in the river's flow. Floating ice often piles up downstream, raising the water level as much as 50 feet (15 meters) and causing severe flooding.

Though entirely navigable, the river has little traffic in its upper course. A canal, linking the Kas and Ket rivers, connects the Yenisei with the Ob River to the west.

University of Washington

YENTAI. See YANTAI.

YEOMAN, yō'mən, a term of Middle English origin, probably a contraction of "young man" and used first to denote a retainer of a king or nobleman. The yeoman in Geoffrey Chaucer's *Canterbury Tales* represents this meaning. Later the term came to be applied to small farmers—particularly, in England, to the small freeholders, who ranked below the gentry. The term is also used as a rating for petty officers and certain others in the British and U.S. navies.

YEOMEN OF THE GUARD, yō'mən, in England, a corps of veteran soldiers employed on state occasions in conjunction with the gentlemen-at-arms as the bodyguard of the sovereign. The yeomen were constituted a corps in 1485 by King Henry VII, and they still wear the costumes of that period. The officers of the corps are a captain (ordinarily a peer), a lieutenant, and an ensign—all army officers. There are also a "clerk of the cheque" and four "exons," besides noncommissioned officers (messengers, sergeants major, yeoman bedgoers, yeoman bedhangers), and 100 privates. The yeomen constitute the oldest military body in England. Their dress is striking: a red tunic, faced and striped with purple and ornamented with gold lace; red knee breeches and red stockings; a ruff and a plumed hat; a steel gilt halberd with a red-and-gold tassel; and an ornamental sword. They are commonly known as Beefeaters, a name also used for the warders of the Tower of London, who wear a similar dress.

YERBA MATÉ. See MATÉ.

The uniform of the Yeomen Warders of the Tower of London closely resembles that of the Yeomen of the Guard.
BRITISH TOURIST AUTHORITY

YEREVAN, ye-re-vān', the capital of the Armenian republic in the Transcaucasian region of the USSR. It is situated on the Zanga (Razdan) River, which drains Lake Sevan into the Aras (Araks) River. Protected by the Gegamski Mountains on the north, Yerevan looks out over the fertile Aras Basin, with Mt. Ararat clearly visible 35 miles (55 km) to the south in Turkey. The city is connected by a branch line to the Tbilisi-Leninakan-Nakhichevan railway and has an airport.

The climate of the upland basin is characterized by cold winters, hot summers, and relatively low precipitation. A dense network of irrigation canals makes it possible to cultivate orchards and vineyards, rice, cotton, and hemp in the fields outside the city. Yerevan is the major manufacturing center of Armenia, supplied with power from the system of hydroelectric stations, known as the Zanga cascade, built by the Soviets along the Zanga River as it drops over 3,000 feet (900 meters) from Lake Sevan to the Aras. Chief among the city's manufactures are aluminum, synthetic rubber and tires, machinery, small hydroturbines, cables, chemicals, textiles, wines, and canned fruits.

Yerevan is one of the oldest cities of the Caucasus, important during the Middle Ages because of its location on a major trade route leading from the Black Sea to India. During the Russo-Persian War the city was taken by the Russians in 1827. From 1828 to 1840 it was the center of the new Armenian oblast, and in 1850 it became the center of Yerevan Guberniya. Soviet power was established in Yerevan in November 1920, and it became the capital of the newly formed Armenian Soviet republic. Since then the city's character has been transformed by industry, and at the same time it has been turned into an impressive cultural center, enriched by monuments in the architectural style of the past. Yerevan State University was founded here in 1920. Population: (1979 census) 1,019,000.

University of Washington

YERKES, yŭr'kēz, **Charles Tyson**, American financier: b. Philadelphia, Pa., June 25, 1837; d. New York, N.Y., Dec. 29, 1905. The son of a Philadelphia bank president, he started as a brokerage clerk in that city at age 17, established his own stockbroking firm at 21, and opened a banking house three years later. After failing in the panic of 1871, he was imprisoned for refusing to give preference to the city of Philadelphia over his other creditors, but was pardoned after seven months. Yerkes soon recouped his losses and in 1882 moved to Chicago, where he acquired a controlling interest in the street-railway system. His methods of financial and political manipulation became a public scandal, however, and he was compelled to sell out in 1899. He subsequently headed a syndicate engaged in building the London underground. Yerkes lived in magnificent style, with mansions in Chicago and New York City. In 1892 he donated funds to the University of Chicago for the construction of the Yerkes Observatory. His career was the basis for Theodore Dreiser's novels *The Financier* (1912), *The Titan* (1914), and *The Stoic* (1947).

YERKES, yŭr'kēz, **Robert Mearns**, American comparative psychologist: b. Breadysville, Bucks County, Pa., May 26, 1876; d. New Haven, Conn., Feb. 3, 1956. He graduated from Ursinus

College in 1897 and took his doctorate at Harvard in 1902. Even while a graduate student, he began his extensive body of scientific publications on comparative psychology, his first studies dealing with the behavior of invertebrates. Yerkes directed the laboratory of comparative psychology at Harvard until 1917 and during these years published research on the behavior of many organisms, from the worm to the great ape. During World War I he took a major role in developing tests of intelligence that were given to more than 1,700,000 men in the United States Army. This was the first large-scale application of scientific psychology ever attempted, and the results were eminently successful.

Following the war, Yerkes assisted in organizing the National Research Council and in 1924 joined the faculty of Yale University, where he remained for the rest of his career. He became the world's greatest authority on the behavior of the higher primates and in 1930 established an experimental station for the study of great apes. This station, located at Orange Park, Fla., was renamed the Yerkes Laboratories of Primate Biology in his honor in 1942.

Yerkes believed that comparative psychology is a method of research, not a separate field of study, and his vigorous curiosity led him also into work on human psychology. Whether dealing with lower animals or with humans, he sought to describe both the biological and the psychological aspects of the organism, and hence referred to his work as psychobiology.

YESENIN, Sergei Aleksandrovich. See ESENIN, SERGEI.

YESHIVA, ya-shŭ'vā (plural, yeshivot), the oldest form of higher Jewish learning, established after the destruction of the second Temple in Jerusalem (70 A.D.) for the purpose of elaborating upon the meaning of the Hebrew Bible. These interpretations were subsequently compiled in the Talmud. The earliest yeshivot were founded in the 3d century in the Land of Israel (Palestine) at Yavne, Caesarea, Tiberias, and other cities and notably in the Babylonian centers of Sura and Pumbedita. A number of others were founded elsewhere in the Middle East and in the Mediterranean and North African area between the 3d and 6th centuries. Subsequently, Jews built yeshivot in western and central European countries between the 8th and 15th centuries.

Owing to persecutions, expulsions, and the decimation of Jewish communities during various Crusades, yeshiva centers were shifted to eastern Europe, primarily Poland, Lithuania, and Russia, where they flourished from the 16th century to the 20th. The curriculum of these schools focused essentially on the study of the Talmud and its commentaries. The yeshiva in Volozhin trained many of the rabbis and talmudic scholars of the 19th century.

The master of a yeshiva was called *rosh* (head of) *yeshiva*. Many young men became lifelong students of rabbinic and talmudic literature. Some were married, often quite young, and lodged and supported in houses provided by the schools. Upon completion of the program of study, such scholars were granted *semichah* (or-

dination) and given the title *rav* (rabbi) or *morenu* (our teacher). Although the Bible is written in Hebrew and the major portions of the Talmud commentaries are in Aramaic, the language of instruction was Yiddish in most of central and eastern Europe.

The yeshiva movement in Europe ended with the Holocaust. A number of schools, however, were revitalized and others established in the new state of Israel, particularly in Jerusalem and Bene Beraq. A noteworthy innovation, the *yeshivot hesder* (post-high school academies) combined rabbinic and talmudic studies with military service.

In North America the earliest yeshivot were the Yeshibath Eitz Chaim (1886) and the Yeshivath Rabbi Isaac Elchanan (1896), both in New York City. These schools merged to become the nucleus of Yeshiva University.

A 20th century development, the Jewish day school, arose in Orthodox communities as a way to combine Judaic religious with secular academic studies on the elementary and high school levels. The typical curriculum usually includes instruction in the Hebrew language for proficiency in reading the original sources, Bible study, and intensive analysis of the Talmud. This is complemented by a full program of secular academic studies, in accordance with local and state requirements for general education. In most Orthodox yeshivot the sexes usually are taught separately, with somewhat different emphases for females, although coeducation is commonly permitted in the elementary grades of the modern Orthodox schools.

Conservative and reform congregations and groups also founded day schools (not identified as yeshivot). These schools are coeducational.

ALVIN I. SCHIFF, *Executive Vice President*
Board of Jewish Education
of Greater New York

YESHIVA UNIVERSITY, *yə-shē'və*, a private liberal arts institution, the main campus of which is situated on the upper west side of New York City. It is the oldest and largest independent university founded under Jewish auspices in the United States.

The university offers a broad range of courses leading to bachelor's, master's, and doctoral degrees. The undergraduate schools emphasize general studies complemented by courses in Judaic lore. The graduate schools prepare students in medicine, law, social work, psychology, Jewish education, and Semitic languages, literatures, and cultures.

Undergraduate men study at the main (up-town) center; undergraduate women at the mid-town center, which includes Stern College and a teachers institute.

Well known in their fields are the Albert Einstein College of Medicine (1955), the Benjamin N. Cardozo School of Law (1976), and the Belfer Institute for Advanced Biomedical Studies (1978). An affiliate, the Rabbi Isaac Elchanan Theological Seminary, prepares students to be Orthodox rabbis and confers ordination.

The university traces its origin to Yeshiva Eitz Chaim (1886), which merged with the Rabbi Isaac Elchanan Theological Seminary (1896) to form Yeshiva College in 1928. The college was granted university status in 1945.

YEVTUSHENKO, *yef-tə-sheng'kō*, *Yevgeni Aleksandrovich* (1933–), Russian poet. He was born in Zima, Siberia, on July 18, 1933. Shortly after his birth his family moved to Moscow. But during World War II he was evacuated to Zima, where he began to write. He returned to Moscow in 1944. Yevtushenko's first poem was published in 1949, and his first volume of poetry, *The Prospectors of the Future*, appeared in 1952. He gained national recognition with his second book, *Third Snow* (1955), which was followed by a long autobiographical poem, *Winter [Zima] Station* (1956).

The rebellious attitudes reflected in some of Yevtushenko's poetry, although they provoked attacks by more orthodox Soviet writers and critics, won him great popularity, and his poems were soon translated into many languages. The first English translation of Yevtushenko's work was published in 1962 as *Selected Poems*. It included *Babi Yar* (1961), a bitter indictment of Soviet unconcern over the Nazi massacre of the Jews of Kiev.

In 1960, Yevtushenko began a series of trips abroad, visiting Africa, Europe, and the United States. In 1962, while in Paris, he published in French translation *A Precocious Autobiography*. Its somewhat unfavorable portrayal of conditions in the USSR prevented its publication there and led to an official rebuke by Premier Khrushchev. In 1965 appeared the long poem *Bratsk Station*, a meditation on history whose symbolic centerpiece is a Siberian power station. *Stolen Apples*, a collection of poems, was published with English adaptations by James Dickey, John Updike, and others in 1971.

Yevtushenko's first novel, *Wild Berries*, was issued in 1982. He also took up acting and wrote for the stage. The cinematographic effects of *Fuku* (1985), an autobiographical work in poetry and prose, reflects his writing and directing for motion pictures. In English translation *Fuku* was published in his collection *Almost at the End* (1987).

YEW, *yōō*, the common name for any of the species of *Taxus*, a genus of evergreen shrubs and trees, in the family Taxaceae. Although the leaves are needlelike, as in many conifers, and resemble some of the species of firs and hemlocks in their flattened two-ranked effect, the yews are not true conifers since their fruits (arils) are bright red and berrylike. Although usually dioecious (male and female flowers on separate plants), yews sometimes have both sexes on different branches of the same plant.

Yews are particularly valued for their horticultural possibilities. Varieties most often cultivated are from the Japanese yew (*T. cuspidata*) and the hardier English yew (*T. baccata*), the latter being more popular in the southern United States. The English yew is found from England to western Asia; the Japanese yew occurs in the Orient. Horticultural forms of these two, and hybrids, range from low compact shrubs to basket-shaped bushes with long spreading branches or tall, narrowly columnar forms (the latter called Irish yew). Yews are especially valued for hedges, since they stand clipping well and produce a dense, dark green growth. For the same reason they have been used in formal gardens, especially

in England, for trimming or training in ornamental shapes. Because of their dark green color, long life, adaptability to various soils and degrees of moisture and shade, and their relative freedom from insects and disease, the yews are considered excellent garden subjects. There are also native American species, but these are not as often used horticulturally. In eastern North America there is *T. canadensis*, commonly called ground hemlock, a shrub with spreading branches; in the West, *T. brevifolia*, in most places a rather leggy tree, but sometimes reaching a height of 80 feet (24 meters); and in the South, *T. floridana*.

The tough, resilient wood of yew trees was valued for bows wherever it was found; the longbows of the English were made of yew when possible, and the Scottish botanist David Douglas (1798–1834), on an early collecting expedition in America, reported that the Indians on the Columbia River favored the Western American yew for their bows. With the modern revival of interest in archery, yew wood is still used for this purpose and is sometimes used also for canoe paddles and in cabinetwork and turning.

Yews have traditionally been used as symbols of long life and even immortality. When palms were not available on Palm Sunday in England, yew was sometimes substituted. Old churchyards and cemeteries usually had a yew tree growing in them, and some of these trees reached a great age. Early poems on death frequently mentioned "sad ewe." Yews are reputed to be more or less poisonous in all their parts, often fatally so; the poisonous property (due to an alkaloid known as taxine) was so well known that "slips of yew" are part of the witches' brew in *Macbeth*.

YEZIDIS. See YAZIDIS.

YGGDRASIL, ig'drə-sil, in Norse mythology, the name of an ash tree whose branches extended up into the heavens and whose three roots were thrust far into the nether world. This cosmic tree has parallels in other religious systems and may conceivably go back to common Indo-European beliefs; but in the form of the myth preserved in the Old Icelandic sources it has absorbed memories of sacred groves, and myths about the Cross of Christ.

While the sources do not entirely agree on its exact nature, it is clear that this tree symbolized all existence and was a vital poetic element in Norse belief. Its name means "the bearer of Odin" and is a metaphor for the gallows on which Odin is said to have hung for nine days, a sacrifice to himself. The tree itself is exposed to "more anguish than men can know," for its roots are gnawed by serpents and its leaves by four stags, symbolizing apparently the endless conflict between life and death. An eagle sits on the topmost bough. Under its spreading branches the gods met in solemn conclave and drank from the sacred well of Urd, or Fate. Thomas Carlyle was much enchanted by this myth and expanded on it in his *On Heroes, Hero-Worship, and the Heroic in History* (1841).

VI DYNASTY. See under KOREA—History.

YIDDISH LANGUAGE, yid'ish, a language used by many Jews of European origin. It has been spoken for almost a thousand years and until the eve of World War II was the most widely used modern Jewish language. Most speakers of Yiddish today live in the United States and Canada, the rest in Israel, the Soviet Union, France, Australia, South Africa, Britain, and Latin America.

Origins. Yiddish arose about the 10th century among Jewish immigrants from France and Italy who settled in the Rhineland region of western Germany. In its earliest form Yiddish was a blend of Middle High German city dialects with Jewish varieties of Old French and Old Italian along with many words and usages of Hebrew and Aramaic origin. Thus, from its very beginning, Yiddish was a language separate and different from medieval German. Its next major development occurred in the 14th century with the eastward migration of masses of Jews escaping the double scourge of the Crusades and the Black Death. As a result Yiddish broke away from German influence and came directly under the sway of Slavic languages. Contact with Czech, Polish, Ukrainian, and Russian not only flooded Yiddish with thousands of Slavic words but deeply affected its grammar, syntax, sound and stress pattern, and semantics. The language flourished in the small towns and villages of eastern Europe where Jews lived in virtual isolation for centuries. By the 19th century, when anti-Semitism forced millions of Jews to leave eastern Europe for the United States and other countries, Yiddish had developed a great religious and secular culture and had, in effect, become the lingua franca, or international language, of most Jews of European origin throughout the world.

Characteristics. Linguists often speak of Yiddish as a fusion language, in reference to the unique synthesis of Germanic, Romance, Semitic, and Slavic elements in its structure. These diverse elements, intimately and seamlessly fused, have given Yiddish its notable ability to express many subtle shades of meaning and emotion (irony, wryness, sarcasm, condescension, scorn) in a wide variety of ways, usually with an overlay of self-deprecating humor.

The language's basic grammar, sound system, and vocabulary are drawn from Germanic sources. Into this structure is built the Hebrew-Aramaic component (comprising about 18% of the lexicon) and the Slavic component (about 16%). In the manner of most Jewish languages, Yiddish uses the Hebrew alphabet and is read from right to left. There are no capital letters in the writing system.

Dialects. Formerly, Yiddish was divided into two major dialectal groups, Western and Eastern. Western Yiddish was widely spoken in Germany, the Netherlands, and other countries west of Poland until about 1700. It then began a process of decline that by the end of the 20th century seemed nearly complete.

Eastern Yiddish, on the other hand, developed into a number of regional dialects. The most important are: Northeastern, spoken in Lithuania, Latvia, and Belorussia; Southeastern, spoken in the Ukraine, Romania, and eastern Galicia; and Central, spoken in Poland and western Galicia. A speaker of Northeastern Yiddish is usually called a *Litvak* ("Lithuanian"). One speaking Central or Southeastern Yiddish is often called a *Galitsyaner* ("Galician"). Both terms of course are misnomers.

COMMON YIDDISHISMS IN ENGLISH

bagel—A crusty roll shaped like a doughnut.
chutza—Brazen gall; nerve.
ganef—A thief; crook.
kibitz—To look on and offer unsolicited advice.
maven—An expert or connoisseur.
megillah—A long, involved or tedious story.
nebbish—Ineffectual; pitiful.
-nik, suffix. One who is, does, etc., as in *no-good-nik, peacenik*.
nosh—A snack or nibble.
nudnik—A tiresome person; nuisance; bore.
schlemiel—A clumsy, bungling person.
shamus—A private detective.
shlep—To drag.
shlock—Shoddy; inferior.
shm- prefix. Used to reduplicate a word in deprecation, as *fancy-schmancy, old-shmold*.
shtick—A routine; act.
zaftig—Plump; buxom.

The most significant difference between the dialects is in the vowels. For example, in Northeastern Yiddish the words for "go to sleep" are *gey shlofn*; in Central Yiddish they are *gey shlufn*; in Southeastern Yiddish they are *gey shluvn*. The pronunciation of Southeastern is usually intermediate between Northeastern and Central. But Standard Yiddish is closest to the Northeastern dialect in pronunciation; grammatically it is closest to Central Yiddish.

Yiddish and English. Yiddish was transplanted in the United States and Britain in the 1880's by Jewish immigrants from eastern Europe. During the next 40 years it thrived on American and British soil as the principal language of Jews at home and in the streets. Especially in the United States, Yiddish cultural activity found intense expression in poetry, fiction, drama, journalism, and scholarship. Nevertheless, the masses of working-class Jews longed to become Anglicized or Americanized as quickly as possible. Their Yiddish became slovenly, filled with English words that replaced perfectly good Yiddish ones. They began to look upon Yiddish as inferior, immigrant "jargon," hardly a language.

This attitude led to a steady decline in the use of Yiddish after the 1930's, paralleling the erosion of other immigrant languages in English-speaking countries. With the decline, however, a nostalgia for the old *mame-loshn* ("mother tongue") set in, and the English of the American-born children of the immigrants began to be peppered with Yiddish words and usages. Because of the special expressiveness of Yiddish, dozens of words and expressions found their way into colloquial American English (see box).

After World War II tens of thousands of Yiddish-speaking immigrants from Europe entered the United States. Their arrival injected new blood into the dying language. Among the newcomers, Hasidic and other Orthodox Jews kept up the use of Yiddish in their everyday life. A new variety of Yiddish-influenced English among American Jews of eastern European origin or descent came to be known as "Jewish English." Furthermore, interest in Yiddish revived among third-generation descendants of immigrants. Yiddish courses were introduced in many colleges and universities. New Yiddish plays were staged and Yiddish "klezmer" music gained popularity. The language thus continued to play an integral and active role in American Jewish culture.

SOL STEINMETZ, Author, *"Yiddish and English: A Century of Yiddish in America"*

YIDDISH LITERATURE, literature in the Yiddish language created by northern European Jews (Ashkenazim). Germany and northern Italy were the medieval and Renaissance literary centers, but eastern Europe became dominant by the 18th century. Modern Yiddish literature developed as a self-conscious, aesthetic expression in the late 19th century. The years 1860 to 1914 spanned the "golden age." Later, the decimation of European Jewry in World War II, the near liquidation of Soviet Yiddish culture by 1948, and the acculturation of Jews in the Americas severely limited creativity in Yiddish.

Old Yiddish Literature. Earliest examples are epic fragments and biblical poems found in a 1382 codex. The twin sources of the poems are German popular literature and Hebraic religious texts. Typical works are the knightly romance *Bovo-Bukh* (1541) by Elia Levita; the biblical epic *Shmuel-Bukh* (1548) by Moshe Esrim Vearba; and the *Mayse-Bukh* (1602), a collection of moral tales. In Poland, Jacob ben Isaac Ashkenazi created the *Tsena Urena* (1616), a popular homiletic work for women. Glueckel of Hameln (1664–1724) wrote unique *Memoirs* chronicling German-Jewish family life.

Hasidism developed a literature about their rabbis, such as *Shivhei Ha Besht* (1815). Nachman of Bratslav's tales *Sippurei Masot* (1815), fusing folk narrative and Hasidic lore, became a major source for modern Yiddish literature.

Literature of the Haskalah, the Jewish Enlightenment, appeared in the late 18th and early 19th centuries. Its first eastern European adherents were Mendel Lefin and Joseph Perl, both rationalists, who attacked Hasidism in satires. Other leading Haskalah writers were Isaac Mayer Dik, Israel Aksenfeld, Shlome Ettinger, and Abraham Baer Gottlober.

Modern Yiddish Literature. Mendele Mocher Sforim, of Russia, is traditionally regarded as the "grandfather" of modern Yiddish literature. His verve, portraiture, and style influenced the development of Yiddish prose. Notable among his works are *The Little Man* (1863), *Fishke the Lame* (1869), and *The Mare* (1873), which depict downtrodden Jews, and the picaresque *Travels of Benjamin the Third* (1878).

Sholom Aleichem, of both Russia and the United States, is considered by many the most original and popular Yiddish author. Prolific in all genres, he developed a tragicomic humor fusing elements of the grotesque with empathy. His vast array of personages provide a broad picture of everyday Jewish life, as in the epistolary series *Menachem Mendl* (1894–1895). His best-known work, *Tevey the Dairyman* (1899), captures through comic and despairing monologues the dislocations of the *shtetl* world and served as a source of the musical *Fiddler on the Roof*.

Isaac Leib Peretz, of Poland, is the third "classic" author. Seeking authentic folk matter, he rewrote hitherto scorned Hasidic legends into sophisticated short stories, such as *Hasidic Tales* (1908) and *Folktales* (1909). He also wrote plays for the Yiddish stage.

Yiddish poetry began with the wedding bards and folk poets. Mikhl Gordon of Poland and Shimon Shmuel Frug of Russia mark the transition into conscious artistry. In the United States it was the "sweatshop" poets of New York, David Edelstadt, Yosef Boshover, Morris Vinchevsky, and above all Morris Rosenfeld, who voiced the aspirations of the immigrant laborers.

A literary group, Di Yunge (1907–1926), established the Yiddish lyric as a personal, aesthetic genre stressing form and effect. Their main journal, *Shrifn* (1912–1926), published Dovid Ignatov, the novelist; Ruvin Iceland, a fine miniaturist; and the humorist Moshe Nadir. Mani Leyb fused form, musicality, and mood in intense sonnets. I. I. Shvarts' *Kentucky* (1925) was an epic of a Jewish peddler. The most original poet was Moshe Leyb Halpern, whose ironic, self-deprecating, and strident style continues to shock. The best Yunge novelist was Yosef Opatoshu with *In Polish Woods* (1921).

New writers from Kiev brought a subtlety of style in prose never again equaled. Dovid Bergelson's masterpiece *After All Is Said and Done* (1913) portrays a heroine trapped between *shtetl* ennui and vapid city modernity. Der Nister constructed symbolic satires inspired by the tales of Nachman of Bratslav, and his novel cycle *The Family Mashber* (1939–1948) combined realism with Hasidic symbolism. World War I ended the golden age of Yiddish literature.

Soviet Yiddish Literature. The Russian Revolution unleashed Yiddish creativity in every genre. Bergelson and Der Nister drew new talent to their journal *Ours* in Kiev. Three major poets emerged: Dovid Hofshteyn, Leyb Kvitko, and Perets Markish. Their verses resonated with Nietzschean freedom and nature worship. Theoretical debate flourished, pitting Bergelson against the Bolshevik critic Moshe Litvakov, who demanded that Jewish art serve the Revolution.

Moscow, Kiev, and Minsk were the main centers of Soviet Yiddish literature. In Moscow a literary group formed about the journal *Shtrom*, with its international Modernist perspective. Influenced by Russian Symbolism and Futurism, the original group included the prose writers Y. Dobrushin and Shmuel Godiner and the poets Aron Kushnir and Dovid Hofshteyn. Under their aegis were brought together such Yiddish figures as Shmuel Rosin, E. Fininberg, the nostalgic Shmuel Halkin, the party poet Itzik Fefer, and the Minsk poets Z. Akselrod and Izi Kharik. Their major themes were pogroms, nostalgia for the *shtetl*, urbanism, and belief in the future.

Soviet Yiddish prose in the 1920's moved to Socialist Realism in the works of Shmuel Persov and Itzik Kipnis. The 1930's brought strict conformity: "Soviet in content, Yiddish in form." Even Bergelson and Der Nister conformed. The poet Moshe Kulbak produced a masterwork, *Zelmenyaner* (1931, 1935), portraying a Jewish family adapting willy-nilly to Soviet realities. The Great Purge of 1937 destroyed Kulbak, the Minsk writers, and even Moshe Litvakov, head of the Communist daily *Truth*. In 1948 all Yiddish cultural institutions were closed. Many Yiddish writers were arrested and shot in August 1952. In 1961 the Soviet government permitted one journal to appear, *Soviet Homeland*, with Aron Vergelis as editor in chief.

Poland and Eastern Europe. Moshe Broderzon and his Yung Yiddish group (1919) brought Modernism to Poland, which by 1922 expanded into full-blown Expressionism in Warsaw. Dubbed The Street Gang, this avant-garde electrified Jewish Poland with the violent verse of P. Markish, the apocalyptic vision of Uri Tsvi Grinberg, and the neoprimitivism of Melekh Ravitch. The major themes were the agony of war, pogroms, the dismal present, and the sad future. Other participants were the realist novelists Oyzer Var-

shavsky (*The Smugglers*, 1920) and I. J. Singer (*The Brothers Ashkenazi*, 1935). Sholem Asch wrote of life in Poland (*Mottke the Thief*, 1917) and in New York (*Uncle Moses*, 1918).

By the late 1920's Modernism waned. The besieged Jewish worker became a key theme for the Expressionist Israel Rabon (*The Street*, 1928). Isaac Bashevis Singer made his debut with his best novel, *Satan in Goray* (1935), a forerunner of magic realism. A Cubist Modernist woman poet, Dvoreh Fogel, linked The Street Gang to Yung Vilne, the last literary movement in Poland. The most talented poets were Leyzer Volf, Hirsh Glik, and the Surrealist Abraham Sutskever. This Vilna world was later chronicled by Chaim Grade in *The Agunah* (1961).

In the ghettos of World War II Yiddish literature continued. Fragments of poems by Miriam Ulianofer remain. Yitskhak Katsenelson's *The Song of the Murdered Jewish People* (1944) survived intact. Y. Y. Trunk escaped to complete his prose epic *Poland* (1944–1953).

Two of the greatest Yiddish poets emerged in Romania: Eliezar Shteynberg, with his witty, pessimistic *Fables* (1932), and Itzik Manger, whose lyric ballads *Medresh Itzik* (1935–1936) retell Bible stories in 1900 folk settings.

The United States. The poet H. Leivik appeared in the United States (1918) with strong verse, combining Jewish messianism and personal suffering. His verse play *The Golem* (1920) became a classic of the theater and cinema. Leivik encouraged the Introspectivists, who created a Modernist Yiddish American movement fusing Imagism, Futurism, and Expressionism. Two key poets, Aron Glantz Leyeles, a master of fixed form and chief theoretician, and Yankev Glatshsteyn, the quintessential Modernist, wrote the manifesto (1920). Joined by N. B. Minkoff, Celia Dropkin, Anna Margolin, and A. Lutzky, their poetry caught the vitality of the American experience. In the 1930's, Abo Shtoltzenberg, Judd Teller, Shloyme Shvarts, and Berish Vaynsteyn, a proletarian Expressionist, appeared. The Holocaust turned poets back to their roots, to remember and to lament. Kadia Molodovsky captured her grief in prickly verse, and Glatshsteyn became nationalistic. After World War II, creativity in Yiddish waned. Even the Nobel laureate Isaac Bashevis Singer ceased writing for the newspaper *The Forward*, once the publisher of almost every Yiddish writer.

Israel: The Last Echo. Poets such as Yosef Papiernikov, Arye Shamri, and the woman poet Rikudah Potash were the rare pioneers using Yiddish in the 1930's while helping to rebuild Israel. In 1949 the Vilna survivor Abraham Sutskever, the last major poet, created *The Golden Chain*, the last important Yiddish literary journal with a worldwide readership. Immigrants from Russia and elsewhere, such as Moshe Yungman, the mystic Yankev Fridman, Rokhl Boymol, and Shloyme Roitman, renewed their song in the new land. A Yung Yisroel group developed, including Rokhl Fishman, Rivka Basman, and Asasia. A single publishing house remained.

YIDDISH THEATER. The origins of theater in Yiddish can be traced to the traditional merrymaking that accompanied the celebration of the Jewish festival of Purim. This gave rise to the Purimshpil (Purim play), about the deliverance of the Jews of Persia from extermination threatened by Haman, the prime minister, through the intercession of Esther, the beautiful Jewish queen of King Ahasuerus. Lighthearted dramatizations of the biblical book of Esther and other legends are mentioned as far back as early talmudic literature. Full of comedy and mime, the Purimshpil was first performed by amateurs and yeshiva students and later by traveling troupes of actors and jesters, and continued to gain popularity until the 18th century.

Other than the cantor, synagogue choir, and *badkhnim* (wedding jesters), the Purimshpil constituted the main form of entertainment among the Yiddish-speaking eastern European Jews. By the mid-19th century the Jews of Europe, having achieved degrees of emancipation and enlightenment, began to look beyond the limited scope of the Purimshpil, setting the stage for the birth of professional Yiddish theater.

Beginning in the mid-19th century, the emerging Haskalah (Jewish Enlightenment movement) found its theatrical expression in the popular Yiddish language of the masses. Much of the early repertoire centered on the struggle between tradition and progress, Old World values and modern European society.

In the early 1860's a group of entertainers, based in the Galician city of Brod and known as the Broder Singers, mimed and clowned their way through the Russo-Polish pale of Jewish settlements. Their typical act combined the wit of Jewish wedding jesters with the slickness of Viennese café entertainers.

Modern Yiddish theater was born in a Romanian wine cellar in the town of Jassy in 1876 with a two-act improvisation by the actor, playwright, and composer Abraham Goldfaden. His earlier appearance in the title role of Dr. Solomon Ettlinger's *Serkele* (1862) marked the beginning of an illustrious theatrical career for Goldfaden, who starred in many of his own musicals and eventually became universally acknowledged as the father of the modern Yiddish theater.

While still in its formative years, Yiddish theater was forced out of its home by the restrictions and pogroms initiated by Czar Alexander III of Russia in 1881. Beginning in 1883, Yiddish theater followed its audience in a mass migration to western Europe and the Americas. By the turn of the century, New York City, with its burgeoning population of immigrant Jews, became the center of Yiddish theater in the New World.

The first professional performance of a Yiddish play in New York took place in Turner Hall in the summer of 1882 with Goldfaden's *The Witch*. In the cast was young Boris Tomashevsky (1868–1939), a Ukrainian-born actor who later opened the People's Theater with his own production of Goldfaden's play. Tomashevsky paved the way for other celebrated actors-turned-producers, such as Jacob P. Adler (1855–1926) and David Kessler (1860–1920), all three of whom were revered as virtual culture-heroes in the Jewish community. Blessed with a huge and passionate immigrant audience, Yiddish theater experienced intense competition among the various companies that sprang up in the free environment of the New World.

On New York's Second Avenue, for example the early Yiddish theater was attended mainly by working-class immigrants, whose enthusiasm outweighed their sense of decorum. As the productions were often as long as five hours, theatersgoers would fortify themselves with bags of food, which they consumed with gusto while voicing critiques of the performances.

The arrival in the United States of Jacob Gordin (1853–1909) from Russia marked the beginning of the "golden age" of Yiddish theater in New York. Gordin waged battle against the sentimental melodramatic offerings of *shund* (low brow) and championed *kunst* (art) theater, which aspired to higher standards of writing and performance and a respect for the written word. During his tenure, Gordin changed the face of the Yiddish theater, writing nearly 80 plays, including such classics as *Mirele Efros*; *God, Man, and the Devil*; and *The Jewish King Lear*, one of his many adaptations of Shakespeare.

Inspired by the writings of Mendele Moche Sforim, Sholom Aleichem, and I. L. Peretz, Yiddish theater continued to grow and mature. Also influential in its development were the works of Sholem Asch, Leon Kobrin, David Pinski, Peretz Hirshbein, and H. Leivik, as well as such non-Jewish masters as Chekhov, Ibsen, Strindberg, Hauptmann, and Gogol.

In the years between the World Wars, Yiddish theater flourished throughout the world. In Poland the Warsaw Yiddish Art Theater operated side by side with the Yung Theater. In the Soviet Union the Moscow State Yiddish Theater founded by Alexander Granovsky, boasted the talents of set designer Marc Chagall and the consummate actor-director Shloyme Mikhoels. Yiddish theater companies thrived in London, Paris, Bucharest, Buenos Aires, and Johannesburg. The most prestigious ensemble was the Vilna Troupe, founded in 1916. In 1919 it presented the world premiere of S. Ansky's *The Dybbuk*, which became the classic masterpiece of the Yiddish theater.

Second Avenue on New York's Lower East Side was at its peak with more than a dozen Yiddish theaters, including Maurice Schwartz' Yiddish Art Theater, launched in 1918, and the ARTEF (Arbeter Teater Farband), founded in 1925. One of Schwartz' most memorable productions, in which he also played the title role, was I. J. Singer's *Yoshe Kalb*, an immediate success and a staple of the Yiddish theater repertoire.

Among the acting luminaries of the early Yiddish theater were Jacob P. Adler, Sigmund Mogulesco, Jacob Ben-Ami, David Kessler, Bertha Kalish, Keni Lipzin, and Esther-Rokhl Kaminska. A later generation of stellar performers included Adler's children Celia, Stella, and Luther, Rudolph Schildkraut, Ludwig Satz, Joseph Buloff, Menasha Skulnik, Leo Fuchs, Zvi Scooler, Seymour Rechtzeit, Muni Weisenfreund (Paul Muni), Ida Kaminska, Jenny Goldstein, and Molly Picon.

During the dark years of the Holocaust, Yiddish theater followed its people into the ghettos where it became a symbol of spiritual resistance, especially in Warsaw and Vilna. After World War II, Yiddish theater came to life in the Displaced Persons camps in western Europe and later in the newly established State of Israel.

The demise of the Yiddish theater has been predicted as often and with as much passion as that of the Yiddish language, but phoenix-like

both the language and its theater have experienced a rebirth. A renewed interest in Yiddish and eastern European Jewish culture has again made New York City the center of a revitalized Yiddish theater. Indicative of this resurgence is the continued viability of the Folksbiene (founded in 1915), the oldest Yiddish theater company in the United States, the Shalom Theater (featuring Mary Soreanu), and the Joseph Papp Yiddish Theater, which launched a successful opening season in the fall of 1988.

YIN SHAN, yin shān, a mountain range in the Inner Mongolian Autonomous Region of China, extending in an east-west direction and rising generally to 6,500 feet (2,000 meters) above sea level. To the north is the Gobi desert; to the south are the great northern bend of the Yellow River (Huang He, Hwang Ho) and the irrigated Hetao (Ho'tao) Plain.

The Yin Shan contains rich deposits of coal and iron ore. These resources account for the development of one of China's largest iron-and-steel complexes at Baotou (Paot'ou, Paotow) on the Yellow River bend. The coal also supplies power plants in the area.

YIN-YANG, yin'yang', a term used in Chinese philosophy to indicate the active and passive principles of the universe. The yang or male force represents the light, active, generative essence. The yin or female force represents the dark, passive, receptive essence. From their interaction all things come into existence and are dissolved.

YINGKOU, ying'kō', a city in China, in the Northeast (Manchurian) province of Liaoning, about 100 miles (160 km) southwest of Shenyang. It is situated on the Hun River, near the mouths of the Hun and Liao rivers, which empty into the Gulf of Liaodong. Although it is the natural outlet for the grain, soybeans, and coal of the Liao Valley, its port is handicapped by rapid deposition of sediments and during the winter by ice blockage. An important oil field adjoins the city limits.

Yingkou (Ying'ou, Yingkow) prospered after 1836 when it took over the trade of the silted upriver port of Niuzhuang (Newchwang). It was opened to foreign shipping in 1858 and developed rapidly as the leading seaport of Manchuria. The city remained prominent until the first decade of the 20th century, but extensive Manchurian railroad construction and the attendant rise of the port of Dalian (Talien, Dairen) led to its decline. It began to recover, especially as a shipping point for soybeans, when it was linked by rail with Manchurian main lines before World War II. Yingkou then became a center of light industry, with food-processing plants, cotton-textile mills, and wood-pulp factories. After the war the Communist government established some heavy industry in the city, notably machine-tool manufacture and petroleum refining. Population: (1982 census) of the municipality, including rural areas, 418,640.

YLANG-YLANG, ē'lāng-ē'lāng, a tropical tree (*Cananga odorata*) of the custard-apple family (Annonaceae), related to the papaw. The Ylang-Ylang (Ilang-ilang) is not impressive as an ornamental, being sparse and awkward, with drooping branches and oblong leaves that are glossy above and hairy beneath. The tiny yellowish flowers have an unusual fragrance and are sometimes used in Hawaiian leis. The genus *Cananga*, which means "flower of flowers," is native to Malaya and has only a few species. But the ylang-ylang has been widely planted in China, India, the Pacific Islands, and the American tropics. Flowers are gathered for perfume, especially in Réunion, Nossi-Bé, Madagascar, and the Comoro Islands. The aromatic oil, obtained by steam distillation, consists of a mixture of several exquisite floral fragrances. It is said, too, to reduce blood pressure in warm-blooded animals and is even substituted for quinine in the treatment of malaria. Cananga oil was introduced into Europe about 1864 and was in great demand for production of perfume.

YMIR, ē'mir, in Norse mythology, a giant who came into being in the primordial world chasm by spontaneous generation between cold and heat. According to the poems of the *Elder Edda* and Snorri Sturluson's *Younger Edda*, he was the first living creature and became the ancestor of the race of giants. Fed by the cow Audhumla, he was killed by the first gods, Odin and his two brothers, Vili and Ve. From his flesh they made the earth, from his blood and sweat the seas, from his bones the mountains, from his teeth the gravel and stones, from his hair the trees, from his brains the clouds, and from his skull the sky. The name Ymir means "the roarer," but the origin of the story is obscure.

YO-YO, yō'yō, a simple toy consisting of a grooved double disk with a string wrapped around the center. The player holds the end of the string, which unwinds as the disk is dropped; then, by slight jerks on the string, it can be made to rewind, bringing the disk back to the hand. Hence the yo-yo is also called a return top. In 18th century England a similar top was known as the quiz or the prince of Wales' toy. In France it was called the bandalore; there was also an ivory counterpart known as the *émigrette*, because it was a favorite with émigré nobles driven from Paris during the French Revolution. The toy is said to have originated in China.

YODEL, yō'dəl, a type of joyful singing native to the Alpine regions of Switzerland and the Austrian Tirol. The name (German, *Jodel*) probably derives from the Latin *jubilare*, meaning "to shout with joy." Yodeling is characterized by decorative, wordless passages in which production of the voice is alternated rapidly between the low (chest) register and falsetto, the break between the two being marked by a light glottal stroke. A yodel, or a song to be yodeled in part, is often called a tyrolienne.

YOGA, *yō'ga*, a Sanskrit word signifying union of the individual soul with the Supreme Spirit and the disciplines for its attainment. It covers a wide field of spiritual practices adapted to different temperaments. *Karma-yoga*, suited to active minds, deals with the performance of duty, in which the doer renounces attachment, motive, and result; *jñāna-yoga*, for philosophical minds, teaches how to discriminate between the real and the unreal and renounce the unreal; *bhakti-yoga*, meant for emotional minds, shows the way to cultivate love of God for His own sake, without hope of reward or fear of punishment; and *rāja-yoga*, suited to the introspective, deals with self-control and mental concentration. The final aim of all these yogas is liberation of the soul from the bondage of matter. *Hatha-yoga* deals mainly with physical exercises.

Rāja-yoga constitutes what is generally known as Yoga, one of the six systems of Hindu philosophy. It is set forth in the *Yogasūtras* ascribed to Patanjali, a sage who flourished during the 2d century B.C. The Yoga and Sāṃkhya systems accept the same philosophical doctrines regarding such matters as cosmology, psychology, and liberation. They agree that man's bondage results from identification of the soul with the body and that his liberation is attained through the knowledge of their separateness. Unlike Sāṃkhya, which is nontheistic, Yoga admits devotion to God as a help to meditation. The God of Patanjali however, is neither creator nor rewarder and punisher, but a special person untouched by misery, desire, or action and its results. Omniscient, He is the teacher of the ancient teachers. Devotion to God is to be cultivated through repetition of the mystic syllable *Om (Aum)* and reflection on its meaning. The soul's essence, pure intelligence, is obscured by mental activities, whose suppression is the main purpose of Yoga. The mind is to be controlled by constant practice of meditation and nonattachment to

material objects. The ultimate result is the suppression of all mental tendencies, conscious or latent.

Yoga lays down eight steps to achieve this end: *yama* (control) and *niyama* (religious observances) are mainly ethical disciplines; *āsana* (posture) and *prāṇāyāma* (regulation of the breath) give the student physical fitness for further Yogic practice; *pratyāhāra* consists in restraining the sense organs from their objects; next come the mental Yogic disciplines—*dhāranā* (holding the mind to a particular object), *dhyāna* (the unbroken flow of awareness of that object), and *samādhi* (complete absorption in the idea behind the object, to the exclusion of its form or outer part). While practicing concentration, the yogi acquires various supernatural powers that belong to the worldly state and must therefore be discarded as obstacles to Yoga. In the end the mind itself is dissolved, and the isolation (*kaivalyam*) of the soul from the body is realized. The disciplines of Yoga have been accepted by all schools of Indian philosophy, including the Buddhist and Jaina.

YOGURT, *yō'gurt* (also **YOGHURT** or **YOGHOURT**), a fermented, slightly acid, semisolid cultured milk food that derives its modern vogue from the Balkans, where it has long been popular. Except for its refreshing taste and wholesomeness as a food, no special virtues were claimed for it until early in the 20th century, when the bacteriologist Élie Metchnikoff, who shared a Nobel Prize in 1908, concluded from his studies on the effect of lactic acid bacteria of the digestive tract that yogurt arrests intestinal putrefaction and thus might be beneficial. Intestinal antibiotic properties are attributed to yogurt which tend to restore the normal intestinal equilibrium.

In western Europe and the United States, where the food has become increasingly popular, yogurt is made almost exclusively from fresh, homogenized, pasteurized cow's milk, to which are added strong yogurt cultures, *Lactobacillus bulgaricus* and *Streptococcus thermophilus*. The milk is bottled and ferments into yogurt inside the bottle, the culturing process taking place in temperature-controlled incubators.

Yogurt has a custardlike consistency and is eaten with a spoon. It contains a higher percentage of lactic acid than other fermented milks, and it is rich in vitamin B complex.

Fresh yogurt has a tangy, keen, and refreshing taste, somewhat like buttermilk, but neither buttermilk nor sour cream contains the specific culture found in yogurt. In addition to plain yogurt, the product is now available sweetened in several

Yokohama, on the western side of Tokyo Bay, is the second-largest city and the busiest seaport in Japan. It is also an industrial and administrative center.

SHOSTAL ASSOCIATES

flavors and also with preserves.

In the Balkans and the Middle East yogurt is also used in food preparation, but in the United States it is usually eaten as a dessert or snack, with or without fruits or jams. Plain yogurt contains no more calories than milk, and since it is more easily digested than milk, it is an excellent food for people with weak digestions, and also for the aged.

President, Dannon Milk Products, Inc.

YOGYAKARTA, yōg-yā-kār'tā, a city in Indonesia and the capital of the special district of Yogyakarta. The city is situated in southern Java at the foot of the volcano Mt. Merapi.

Yogyakarta (formerly Djokjakarta and Jogjakarta) is a cultural and educational center. The skyline of the city is dominated by the 18th century palace of the sultans of Yogyakarta. Part of the palace now houses Gajah Mada University, founded in 1949. The city is also the seat of the Java Institute, which was founded in 1921 to advance the study of Javanese culture. There are several other institutions of higher education and several museums.

Yogyakarta has highly developed silvercraft, wood-carving, and leather-goods industries. It is also a center for the manufacture of batik cloth.

The city was founded in 1749 by Sultan Hamengku Buwono I. In 1755, after the Dutch had divided the kingdom of Mataram into Surakarta and Yogyakarta, the city was the capital of the new Dutch-controlled sultanate under Hamengkun. Yogyakarta was the center of a revolt (1825-1830) led by Prince Diponegoro against the Dutch and as such became famous as a stronghold of the Javanese independence movement. From 1945 to 1949 the city was the temporary capital of Indonesia. Population: (1980) 398,727.

YOKKAICHI, yōk-kī-chē, a seaport and industrial center in Japan. The largest city in Mie prefecture, central Honshu, it is situated on the western side of Ise Bay, 23 miles (37 km) by rail southwest of Nagoya.

Yokkaichi was originally a market town. In

the 17th century it became one of the 53 post, or relay, towns on the Tokaido, the main road between Kyoto and Edo (modern Tokyo). Yokkaichi was made a city in 1897 and in 1899 was designated a port for foreign trade, serving in part industrial Nagoya, a function it lost with the improvement of Nagoya Harbor. By 1935, Yokkaichi's factories were producing textiles, chemicals, glass, and foodstuffs. After 1955 large-scale petroleum-refining and petrochemical industries were established, creating a serious problem of air pollution. Yokkaichi is also known for its production of a type of porcelain called Bankoyaki. Population: (1980) 255,442.

University of Washington

YOKOHAMA, yō-kō-hā-mā, a city in Japan, on the southwest shore of Tokyo Bay, 18 miles (29 km) by rail southwest of Tokyo. Japan's second-largest city and leading seaport, Yokohama also is a major industrial center and the capital of Kanagawa prefecture. The city occupies the eastern end of the Tama dissected uplands and alluvial lowland, with its port on the inner curve of a sand spit.

History Yokohama is historically important in the establishment of relations between Japan and the United States. In 1853, Commodore Matthew C. Perry dropped anchor off Uraga, south of Yokohama; on his return visit a year later, his ships anchored at Kanagawa (now part of Yokohama), and the Kanagawa Treaty was concluded, providing for the limited opening of two ports, Shimoda and Hakodate, to American ships. In July 1858 a commercial treaty was signed, including Kanagawa among the six ports to be opened to foreign trade, and in 1859 the shogunate transferred the trading activities to nearby Yokohama, which was then only a small fishing village.

Yokohama grew rapidly as a port after the first railroad built in Japan connected it with Tokyo in 1872, and it became a city in 1889. Its hinterland formerly embraced not only eastern Japan but also much of the central and western part of the country. Its relative importance in foreign trade, however, has tended to diminish, partly because of the rapid growth of shipping facilities in other industrial areas.

On Sept. 1, 1923, Yokohama was almost entirely destroyed by a great earthquake, tidal wave, and fire, and in May 1945 Allied air raids ruined practically all of the business district and half of the harbor facilities. It has since been rebuilt along modern lines. During the occupation of Japan following World War II, the port was taken over by the Allied powers and closed to civilian use. In 1952 it was reopened, and its recovery as a commercial port began, strengthened by its excellent railway facilities and its easy access to Tokyo. Yokohama now serves as a port for transpacific commercial ship traffic.

Economy.—At one time Yokohama specialized in the export of raw silk to the United States and other Occidental countries and was known as the "silk port." Tea was another export staple. After 1934, however, cotton goods became paramount, and by 1955 steel and iron ranked as the leading items. Machinery is also an important export, as is the traditional raw silk.

Because of Yokohama's position as a foreign trade center with access to imported raw materials, there is considerable manufacturing, especially in the eastern section where, since 1912, a large shallow offshore area has been reclaimed for industrial purposes. The principal industries are shipbuilding and the manufacture of transportation equipment, primary metals, electrical machinery and equipment, and chemicals. Commercial structures, the customhouse, and prefectural and other official buildings are in the central part of the city, while the western part is residential.

Points of Interest.—On the eastern side of Sakuragicho Station, overlooking Yokohama, are three hills, Noge-yama, Iseyama, and Kamon-yama. On Noge-yama is Noge-yama Park, largest in the city, which was created after the great earthquake of 1923. The park has a fine example of Japanese gardening, an open-air theater, a modern concert hall, and a zoo. Nearby stands the Municipal Library. On Iseyama is the Iseyama Daijingu, a Shinto shrine, which is a branch of the great shrine of Ise. Kamon-yama is named after Ii Kamon-no-kami (1814–1860), who was premier for Shogun Iemochi and was active in opening Yokohama to foreign trade. The Prefectural Library and the Music Hall are nearby. Perhaps the most beautiful spot in Yokohama is the Sankeien (Three Glens) Garden, which covers an area of over 40 acres along the shores of Tokyo Bay in the southwestern part of the city. The garden contains many historical buildings brought from other parts of Japan. The three-storied pagoda, over 500 years old, which dominates the park, was brought from the Tomyoji Temple at Kamo, Kyoto. Hassei-den (Hall of Eight Sages) near the Sankeien Garden houses images of Gautama (Buddha), Confucius, Socrates, Christ, Prince Shotoku, and the Buddhist priests Kobo-Daishi, Shinran, and Nichiren. Another point of great interest is the Kusunokicho Kiln, which produces the famous Satsuma ware (also known as Ryosai or Sumida ware). The kiln, originally founded near Nagoya in the 17th century, was moved near the Sumida River in Edo (Tokyo) in 1848 and finally transferred to its present site following the Meiji Restoration in 1868.

There are four universities in the city: Kanagawa and Kanto Gakuin (both private), Municipal Yokohama University, and Yokohama National University. Eleven miles southwest of Yokohama at Station is the famous Kanazawa Bunko

(Library), founded in 1275, which contains many historical books and documents. Also located in the suburbs is Yokohama Dreamland, a Disneylike amusement park. Population: (1981) 2,806,523.

GEORGE H. KAKIUCHI
University of Washington

YOKOSUKA, yō-kōs-kā, city, Japan, in Kanagawa Prefecture, on Honshu Island, at the southwest end of Tokyo Bay, 12 miles by rail south of Yokohama. The city developed as an important naval base and arsenal after the Meiji Restoration in 1868. In the eastern part are two fine natural deepwater harbors, Yokosuka and Nagaura, occupying former drowned valleys. Originally Yokosuka was located at the neck of Cape Kachiriki, where the Tokugawa shogunate established a shipbuilding yard in 1866. Then, in 1884, the Meiji government set up a naval station and built ship-repair docks and other naval facilities in Yokosuka and Nagaura bays. Yokosuka became a city in 1907 and gradually absorbed the adjacent towns and villages as the needs of the naval base and arsenal expanded. Because of the narrowness of the coastal lowlands, it has gradually moved up the adjacent hillsides and small narrow valleys, the latter interconnected by many tunnels built for military purposes. After World War II the United States Navy occupied the naval base.

The only important manufacturing industry is shipbuilding, at Uraga, about three miles southeast of the naval base. Nagaura has become a commercial port and a base for ships engaged in fishing, especially whaling operations in the Antarctic Ocean. Within the municipality a few minor agricultural settlements on the uplands grow rice, wheat, and sweet potatoes, and there are some small fishing villages along the coast.

The Yokosuka area contains some interesting historical sites. At Kurihama, just south of Uraga, Commodore Matthew C. Perry formally handed a letter from President Millard Fillmore of the United States to the Tokugawa shogun's representative in 1853, and it was off Uraga that Perry's fleet dropped anchor. In Tsukayama Park are the tombs of William Adams and his Japanese wife. Adams, who was the first Englishman to enter Japan (1600), became adviser and shipbuilder to the first Tokugawa shogun. At Cape Kannon, which is east of the naval base, is the first modern lighthouse in Japan. Population: (1981) 426,270.

University of Washington

YOKUTS INDIANS, yō'kats, an important division of the Penutian linguistic family, formerly living in the San Joaquin Valley, from the mouth of the San Joaquin River in the north to the foot of the Tehachapi Mountains and the slopes of the Sierra Nevada. The name is Indian for "person." Actually a loose confederation of about 40 closely related smaller tribes, the Yokuts were one of the most numerous California peoples, and their way of life reflects the general cultural pattern of the central Pacific Coast region, with some extremely interesting differences.

Each tribe had a hereditary chief. Villages consisted of a single row of wedge-shaped communal houses thatched with tule, and sweat-houses were in common use. Acorns were a staple food, and small game, including even deer and elk, were captured regularly. The Yokuts

were one of the few tribes to use the dog for food, but they refused to touch the coyote or rattlesnake. The women were chaste, prior to white settlement; marriage was by purchase, and the husband moved into his bride's home. Clothing was scanty; women wore the bark apron common to most California peoples, and often tattooed the face and body. Religious life was moderately organized and many animal spirits were known; shamanism played a very important role in the various rituals. One unique feature was a rattlesnake ceremony, reminiscent of the more elaborate snake dance of the Hopi. Boys were initiated with a jimsonweed or *tolache* ceremonial. The dead were either buried or cremated, and the Yokuts observed the usual annual mourning ceremony, common throughout California, when hundreds of Yokuts congregated to weep, dance, and feast.

Yokuts women wove very fine basketry, making extensive use of quail and woodpecker feather decoration; the famous Tulare gambling trays and Tulare bottleneck baskets are familiar exhibits in many museums. One art peculiar to central California was the manufacture by Yokuts women of a crude pottery, which they may have learned from neighboring Shoshonean peoples. Like Tulare gave a disproportionate importance to one segment of the confederacy, which became known as Tulareños, or Lake Tulare Indians. Unfortunately, this name eventually became attached to the entire Yokuts group, resulting in considerable confusion.

The Yokuts are a remnant of a once numerous people, whose population at its height probably numbered some 10,000. Continued warfare with the Paiutes, who pressed on them from the east, resulted in some depopulation; but the later and much more disastrous aggression by white settlers, who found the Indians occupying land they wanted, practically exterminated many of the tribes. Today fewer than 600 survive, although in spite of their shrinking population they have managed to retain an extremely high degree of blood purity.

FREDERICK J. DOCKSTADER,
Director, Museum of the American Indian, Heye
Foundation, New York City.

YOM KIPPUR, yôm kîp'ar (Heb. for DAY OF ATONEMENT), the most solemn of all Jewish holidays, occurring on the 10th of Tishri (late September or early October). It is observed with prayer and by complete abstinence from food and drink, sexual intercourse, and all work, and concludes the "ten days of repentance" which begins with New Year's Day on Tishri 1. Yom Kippur is of Biblical origin (Leviticus 16; 23:26-32), and down to the destruction of the Jerusalem Temple by the Romans (70 A.D.) it included the dispatch into the desert, "for Azazel," of a scapegoat which was believed to take with it the people's sins. A lengthy description of the elaborate Yom Kippur ritual of the Jerusalem Temple still forms part of the services, which among Orthodox Jews take up the whole day. The rites begin on Yom Kippur Eve (Tishri 9) with the Kol Nidre prayer, originally intended to cancel vows of conversion to Christianity made under duress, but later reinterpreted as referring to vows between man and God. The confession of sins, repeated several times during the day, enumerates only ethical lapses, because only these, not crimes against fellow men, were

believed to be atonable by performing the Yom Kippur ritual. The service ends at sundown on Tishri 10 with the closing prayer (Neilah), on the hopeful note that all who have repented have been inscribed by God into "the Book of Life" for the ensuing year.

RAPHAEL PATAI.

YON, yôn, **Pietro Alessandro**, Italian-American organist: b. Settimo Vittone, Italy, Aug. 8, 1886; d. Huntington, N.Y., Nov. 22, 1943. He studied at the Milan and Turin conservatories and at the Academy of St. Cecilia in Rome, where he graduated with a first prize in 1905. He was organist at St. Peter's in Rome from 1905 to 1907, when he went to the United States to become organist of St. Francis Xavier's in New York City (1907-1926, except for a brief interval). From 1926 to his death he was organist of St. Patrick's Cathedral in New York City. Yon also gave many organ recitals in European and American cities. He composed extensively in liturgical and other sacred forms, but his creative gift was not of the order of his ability as an instrumentalist.

HERBERT WEINSTOCK.

YONEZAWA, yô-ně-zä-wä, city, Japan, in Yamagata Prefecture, on Honshu Island, 194 miles north of Tokyo. It is surrounded by towering mountains, except in the north. Formerly a castle town of the Uesugi family during the Tokugawa shogunate (1603-1867), it has many antiquities despite disastrous fires in 1917 and 1919, which compelled much rebuilding. The principal industry since the 17th century has been silk weaving, which encourages a surrounding agricultural concentration on mulberries (fodder for silkworms), supplementing rice, fruit, and tobacco. Factories are of the small-scale cottage type, though modern, and their products are of high quality. The Japanese rayon industry also originated here. Six miles west is Onogawa, noted for its hot springs. Pop. (1980) 92,823.

DAVID H. KORNHAUSER.

YONGE, yüng, **Charlotte Mary**, English novelist: b. Otterbourne, Hampshire, England, Aug. 11, 1823; d. there, March 24, 1901. She was educated at home. Under the influence of John Keble (q.v.), vicar of the neighboring village of Hursley, she identified herself with the High Church faction—later called Anglo-Catholic—in the Church of England. As her talent developed, Keble urged her to use it to expound her religious views, and she was only too ready to comply. Her first full-length novel, *The Heir of Redclyffe* (1853), was immediately successful, partly because of the very qualities—tearfulness and didacticism—which most daunt later readers. Despite preachiness, however, her stories moved. She branched out into historical romance (*The Lances of Lynwood*, 1855, and others) and added juveniles, biography, popular history, and Scripture readings. She also edited (1851-1899) the *Monthly Packet*, a children's magazine. Her total output was some 160 volumes.

DELANCEY FERGUSON.

YONGSAN RIVER, yüng-sän, river, Korea, in South Cholla Province (South Korea). Rising in the mountains north of Tamyang, the Yongsan flows in a southwesterly course for 72 miles past Naju and into the Yellow Sea above the port city

of Mokpo. Its basin of nearly 1,100 square miles comprises most of the area of the productive South Cholla plain.

EDWARD W. WAGNER.

YONKERS, yŏng'kŏrz, city, New York, in Westchester County, on the east bank of the Hudson River, on a hilly terrain overlooking the Palisades of the opposite Jersey shore. Yonkers is both a residential and industrial center, the largest city in the county and fifth largest in New York State. On the south it adjoins Bronx Borough of New York City; on the north and east, Hastings-on-Hudson, the town of Greenburgh, and the communities of Scarsdale, Eastchester, Tuckahoe, Bronxville, and the city of Mount Vernon, all in Westchester.

Yonkers' industries include the world's largest manufacturer of elevators and escalators, dating from 1854, and the largest producer of liquid sugar for industrial purposes. Other products include wearing apparel, nurses' uniforms, plastics, pharmaceuticals, pipe organs, metal and wire products, aerosol valves, and electrical and electronic equipment. The submarine pipeline Pluto, used to carry gasoline to fuel the D-day invasion in World War II, was made in Yonkers, as was the 3,000-mile Styroflex coaxial cable that constitutes the heart of the Distant early Warning (DEW) system. The city is served by federal and state highways, a railroad, and river and oceangoing shipping.

Sarah Lawrence College, for women, and St. Joseph's Seminary (Roman Catholic) are located in Yonkers, as is the Boyce Thompson Institute for Plant Research, opened in 1924. The Sprain Brook Branch of the Yonkers Public Library is an outstanding modern structure. Another point of interest is the Hudson River Museum, in Trevor Park, with three art galleries, a planetarium, and a notable astronomical exhibition hall. St. Andrews Golf Club was organized in 1888 with one of the first golf courses in the United States, and the first unofficial United States Open took place here in 1894. Yonkers Raceway is a nationally famous harness-racing track.

History.—Yonkers' history goes back to 1639, when the so-called Keskeskeck Purchase, including approximately the present area of the city, was made from the Indians by the Dutch West India Company. Title passed through the New England Company in 1646 to Adriaen van der Donck, first lawyer and historian of New Netherland, from whose title (*jonkheer*) the city's name is derived. Frederick Philipse (q.v.) acquired much of the van der Donck land in 1672 and succeeding years and built the first Philipse manor house here in 1682. In 1779, the third and last lord of the manor lost his lands because of loyalty to the crown during the American Revolution. Philipse Manor, a fine colonial building, now open to the public and administered by the New York State Education Department in collaboration with the American Scenic and Historic Preservation Society, houses the priceless Cochran Collection of 69 portraits of presidents of the United States, painted by Gilbert Stuart and other leading artists.

Yonkers was incorporated as a village in 1855 and as a city in 1872. It has had the city-manager form of government since 1940. Population: 188,082.

GRINTON I. WILL,
Director, Yonkers Public Library.

YONNE, yŏn, department, France, in the north central part of the country, which was formed from the old Sénonais region of Champagne and parts of Burgundy (Bourgogne), Orléanais, and Nivernais. The capital is Auxerre. The area is 2,881 square miles. Yonne is bounded by the departments of Seine-et-Marne, Aube, Côte-d'Or, Nièvre, and Loiret, and is named after the Yonne River (q.v.), which flows north-northwest through its entire length. The Armaçon River flows through its eastern section and the Loing River rises in the south. The Puisaye region in the southwest belongs to the Loire Basin. The rolling country of the Île-de-France, which prevails in the north, gradually gives way to the granitic hills of the Morvan (2,000 feet) in the southeast. The climate is mild, except in the Morvan.

The department produces wheat, cattle, vinegar, and, above all, wine, notably the famous Chablis. Minerals include iron, building stones, lithographic stones, and potter's clay. Textiles, sugar, glass, and glue are manufactured, and wool, ship timber, and charcoal are also produced. There are castles of the Renaissance period at Ancy-le-Franc and Fleurigny, and the large monastic Church of the Madeleine at Vézelay is a masterpiece of the Romanesque style. Chief towns, besides Auxerre, are Avallon and Sens. Pop. (1982) 311,019.

RENÉ GIRARD.

YONNE RIVER, river, France, in the central and north-central part of the country, one of the Seine's most important tributaries. Rising on the northern slope of Mont Beuvray in the Morvan, it flows 182 miles north-northwest through the departments of Nièvre and Yonne, joining the Seine at Montereau-Faut-Yonne. Its picturesque course passes Clamecy, Auxerre (head of navigation), Joigny, and Sens. The Nivernais Canal runs alongside between Corbigny and Auxerre. Its tributaries are the Cure, which joins it above Auxerre; the Serein; and the Armançon, which joins it above Joigny.

YORCK VON WARTENBURG, yŏrk'fŏn vār'tau-bŏŏrkŏ, COUNT (Johann Hans David) Ludwig, Prussian field marshal: b. Potsdam, Germany, Sept. 26, 1759; d. Klein-Oels (near Breslau), Oct. 4, 1830. He served in the Polish campaign of 1794, and in 1806 commanded the rear guard of Gen. Gebhard von Blücher's army in the retreat from Jena to Lübeck, where it capitulated. Yorck opposed the reforms that Gen. Gerhard von Scharnhorst and Gen. Neithardt von Gneisenau introduced in the Prussian Army after 1807. During Napoleon I's Russian campaign in 1812, he commanded the Prussian corps and during the retreat, concluded with the Russians at Tauroggen (now Taurage, Lithuania), a neutrality convention (Dec. 30, 1812) for his troops, which became the signal for the rise of Prussia against Napoleon. In the Wars of Liberation Yorck commanded a corps in Blücher's Silesian army. His greatest single military accomplishment was the hard-fought crossing of the Elbe River at Wartenburg on Oct. 3, 1813, which made possible the Battle of Leipzig on October 16–19. On March 9–10, 1814, he helped decisively in the Prussian victory at Laon. He was made a count in 1814.

Hajo HOLBORN
Author of, "A History of Modern Germany"

YORICK, yôr'ík, in Shakespeare's tragedy *Hamlet*, the king's fool, whose skull is apostrophized by Hamlet in Act V. The name Yorick was used by Laurence Sterne in *Tristram Shandy* (1759-67) for the parson, intended as a portrait of himself; and as his author's pseudonym in *A Sentimental Journey* (1768).

YORITOMO, yô-rê-tô-mô (in full **YORITOMO MINAMOTO**), Japanese shogun, founder of the Kamakura shogunate: b. 1147; d. 1199. During the 12th century the local aristocracy in Japan became transformed into a professional military class (the *bushi*). Rivalry between the two most influential *bushi* clans, the Taira and Minamoto, was transmitted to the imperial court in Kyoto, as members of the military aristocracy were used by the court for military and police purposes. In 1160 the Taira defeated and killed Yoshitomo Minamoto, head of the Minamoto clan, and imposed a dictatorship on the court. Yoshitomo's sons, Yoritomo and Yoshitsune (q.v.), were spared death and sent into exile. In 1180 remnants of the Minamoto received a secret call from the court to rid the country of the Taira. Yoritomo succeeded in raising forces in eastern Japan (the Kanto) and under the leadership of several Minamoto generals, notably his half brother Yoshitsune, drove the Taira from Kyoto and ended their power at the Battle of Dan-no-ura in 1185.

Meanwhile Yoritomo consolidated his hold over the Kanto, enlisting all possible *bushi* as his retainers (*gokenin*) and confirming their landholdings. He was granted successively the titles of military governor in chief (*sô-shugo*), general of the right imperial guard (*ukonoe-taishô*), and in 1192 barbarian-subduing generalissimo (*sei-i-tai-shôgun*). He established his headquarters (*bakufu*) at Kamakura and began to exercise increasing control over the country.

Yoritomo did not usurp authority from the imperial court but exercised delegated military and police functions. However, since he was able to appoint his retainers as provincial military governors (*shugo*) and land stewards (*jitô*), he was in possession of a nationwide organization with far-reaching military and even civil powers. Yoritomo thus set the patterns of military rule which lasted until the mid-19th century and which by the 14th century left the emperor with only ritualistic functions. The two subsequent shogunal lines, the Ashikaga and Tokugawa, claimed descent from the Minamoto.

JOHN W. HALL,
Griswold Professor of History, Yale University.

YORK, yôr'k, CARDINAL (HENRY BENEDICT MARIA CLEMENT STUART), Jacobite pretender to the British throne: b. Rome, Italy, March 6, 1725; d. Frascati, July 13, 1807. Second son of the Old Pretender (see STUART, JAMES FRANCIS EDWARD), he was probably given the title of duke of York at birth and was baptized by Pope Benedict XIII. He was made a cardinal in 1747, shortly after his elder brother Charles (the Young Pretender) had failed in his invasion of Britain. When Charles died on Jan. 31, 1788, York inherited the Jacobite claim to the crown of Britain, assuming the title of Henry IX, "not by men's wishes but by God's will," as the Eng-

lish of the Latin medal struck for the occasion has it. The amiable cardinal enjoyed high offices and rich benefices, but at the French Revolution his revenues dried up, and he fled to Venice. George III gave him a yearly pension of £5,000. After the Concordat of 1801, Cardinal York returned to Rome, and Pius VII made him dean of the Sacred College and bishop of Ostia and Velletri. At his death the male line of the royal house of Stuart-descendants of Robert II, king of Scotland (1371-1390)—became extinct. The cardinal's will bequeathed some of the British crown jewels to the prince of Wales, the future George IV. See also JACOBITES.

WALLACE BROCKWAY.

YORK, DUKES OF, in the English peerage. The title was first held by EDMUND OF LANGLEY (1341-1402; surnamed for his birthplace, King's Langley, Hertfordshire), fifth son of Edward III. Edmund received the title from his nephew Richard II in 1385, but as regent in 1399 he deserted to Henry, duke of Lancaster, also a nephew, who defeated Richard and assumed the throne as Henry IV. Edmund's elder son, EDWARD OF NORWICH (1373?-1415), 2D DUKE OF YORK, a shifting politician, was crushed to death at the Battle of Agincourt. Edmund's grandson, RICHARD PLANTAGENET (1411-1460), 3D DUKE OF YORK, was the first to use the surname Plantagenet, no doubt to emphasize his descent from the Angevin kings, whose ancestor, Geoffrey of Anjou, had used a sprig of the broom plant (*planta genista*) as his personal emblem. Deeming his own claim to the throne superior to that of the Lancastrian Henry VI (York was descended from the third son of Edward III; Henry VI from the fourth), York in 1450 inaugurated the dynastic and constitutional struggle that is romantically called the Wars of the Roses (York, the white rose; Lancaster, the red). In June 1460 the Yorkists triumphed, and Duke Richard was admitted heir to the throne, only to die at the Battle of Wakefield later in the same year. His son, however, became EDWARD IV (r. 1461-1470; 1471-1483), whose own sons, EDWARD V (r. 1483) and RICHARD PLANTAGENET (1472-1483), DUKE OF YORK, known as the princes in the Tower, were reputedly murdered on the orders of their uncle Richard III, the last Yorkist king. When Richard III was defeated and killed at the Battle of Bosworth Field in 1485, the throne passed to Henry VII, a Tudor, whose mother, Margaret Beaufort, was descended from John of Gaunt. By marrying Elizabeth, eldest daughter of the Yorkist Edward IV, Henry VII reconciled the conflicting claims of the descendants of Edward III. See also GREAT BRITAIN AND NORTHERN IRELAND, UNITED KINGDOM OF—21. *History* (Later Middle Ages): Wars of the Roses; ROSES, WARS OF THE.

Since the time of Edward IV, who created his younger son duke of York in 1474, the title has often been given to the second son of the English sovereign. By the deaths of elder brothers, three successive dukes of York became kings as Henry VIII, Charles I, and James II. George I in 1716 created his youngest and last surviving brother, ERNEST AUGUSTUS (1674-1728), duke of York and Albany; the Scottish title Albany, equivalent in importance to that of York, alluded tactfully to the union of the two crowns in 1707. EDWARD AUGUSTUS (1739-

1767), second son of Frederick Louis, prince of Wales, and FREDERICK AUGUSTUS (1763–1827; see YORK AND ALBANY, DUKE OF), second son of George III, also enjoyed this double title, receiving it in 1760 and 1784, respectively. Queen Victoria broke with tradition when she elected to confer the title Duke of Edinburgh on her second son, Prince Albert, but in 1892 she gave the title Duke of York to her grandson the future George V, second son of the prince of Wales (later Edward VII). George V's second son, the future George VI, became duke of York in 1920. Andrew, the second son of Queen Elizabeth II (daughter of George VI), was created duke of York on July 23, 1986.

WALLACE BROCKESY

Consultant to the Bollingen Foundation

YORK, Alvin Cullum (1887–1964), American soldier. He was born in Pall Mall, Tenn., on Dec. 13, 1887. Although he requested exemption from active duty owing to his religious beliefs, he became a popular hero of World War I. As a corporal in Company G, 328th Infantry Regiment, 82d Division, he took part in the Argonne-Meuse offensive. On Oct. 8, 1918, near Châtel-Chéhéry, he crushed a German machine-gun battalion single-handedly, killing at least 25 and capturing 132 prisoners. York was made a sergeant and given more than 50 decorations and honors, including the Congressional Medal of Honor.

After the war York settled on a farm in Fentress county given to him by the state of Tennessee. He requested the establishment of the York Foundation, which supported an industrial school and a Bible school. *Sergeant York: His Own Life Story and War Diary* was published in 1928; *Sergeant York*, a film based on his life, was made in 1941. York donated part of his royalties from the film to the York Foundation. He died in Nashville, Tenn., on Sept. 2, 1964.

YORK, city and county in North Yorkshire, England, on the Ouse River, about 200 miles (320 km) north of London and 22 miles (35 km) north-east of Leeds. It was the traditional county town of Yorkshire but was not included in any of the county's three "ridings," each of which had its own administrative center (see YORKSHIRE).

York is unique for its 14th-century walls and narrow medieval streets; the walls, 2.5 miles (4 km) in circumference, follow in part the line of Roman walls, whose remains can be seen. Two mounds, one walled, were erected by William I. St. Mary's Abbey Church and St. Leonard's Hospital (both in ruins) date from the 13th century; the Merchant Adventurers' Hall, from the 14th century; the Guildhall (guttered by bombs in 1942), St. Anthony's Hall, and the Merchant Taylors' Hall, all from the 15th century. Within the walls are York Minster (see YORK CATHEDRAL) and many other medieval churches. There are three notable museums: one of Roman York, another of medieval York, and the National Railway Museum. Modern York produces chocolate, cocoa, glassware, chemicals, scientific instruments, and machinery, and has important railway shops. Tourism is also an important industry. Both the University of York, founded in 1963, and the seat of the archbishop of York, Bishopthorpe, lie outside the city limits of York.

As Eboracum, York was the capital of Roman Britain. Under the Saxons it was the capital of

Northumbria and a noted seat of learning, where Alcuin was born and taught in the 8th century. Population: 123,126 (1981 census).

H. GORDON STOKES

Author of "English Place-Names"

YORK, town, Maine, in York county, on the Atlantic Ocean, about 45 miles (72 km) southwest of Portland. It includes the summer resorts of York Harbor and York Beach. Chartered by Sir Ferdinando Gorges in 1642 as the city of Gorgeana, it was settled as Bristol plantation in 1638, changing its name to Agamenticus borough in 1641. In 1652 it passed under the control of Massachusetts and was reincorporated as York. Attacked by Native Americans, the settlement was almost wiped out in 1692. York has fine examples of colonial architecture; its jail, now the Old Gaol Museum, is the oldest English public building in North America that still stands and is open to the public. Population: 9,818.

YORK, city, Nebraska, seat of York county, 45 miles (72 km) west of Lincoln, on Beaver Creek, a branch of the Big Blue River. It lies in a rich prairie region and is a trading center for a wide farming and stock-raising area. A center of light industry including the manufacture of farm implements and mobile homes, York also has a robust transient-tourist trade. York College, a coeducational institution, was founded in 1890 and is controlled by the Church of Christ. York was founded by agents of the South Platte Land Company, platted in 1869, and incorporated in 1872. The neighboring settlement of New York was annexed in 1880. Population: 7,884.

YORK, city, seat of York county, Pennsylvania, 25 miles (40 km) by road south-southeast of Harrisburg, in the rich Pennsylvania Dutch farming region. York is the commercial center for one of the state's leading agricultural counties and an important producer of air-conditioning and refrigerating equipment, turbines, farm and construction machinery, wire cloth, roofing materials, and paper products. It is served by the Harrisburg International and York airports.

York has fine colonial homes and churches. The Friends' Meetinghouse, surrounded by the burial ground, has been in continuous use since the original part was built in 1765. York has a symphony orchestra and a history museum, and is the home of York College of Pennsylvania (coeducational), founded in 1941. The annual York Interstate Fair has long been a famous event in the area.

The city dates from 1741, when it was founded as a manorial town by the Penn family, most of the settlers being Germans, Scotch-Irish, and English Quakers. It was incorporated as a borough in 1787 and as a city in 1887. During the Revolutionary War the Continental Congress fled from British-occupied Philadelphia to York, where it met from Sept. 30, 1777, to June 27, 1778. During its sessions here the Articles of Confederation were adopted. Continental Square in present-day York marks the site of the colonial courthouse in which the Congress met. In 1863 the Confederates under Gen. Jubal Early took York, the largest community north of the Mason and Dixon Line to be occupied by Southern forces. Population: 42,192.

DANIEL R. PORTER

The Historical Society of York County

YORK, House of, English royal house, a branch of the Plantagenet family, dating back to Edmund of Langley (1341-1402), who was created 1st duke of York in 1385. Richard Plantagenet (1411-1460), 3d duke of York, was head of the house; his sons Edward IV (r. 1461-1470; 1471-1483) and Richard III (r. 1483-1485) and his grandson Edward V (r. 1483) were kings of England. The house of York and the house of Lancaster contended for the English throne until they were united in 1486 by the marriage of Henry VII and Elizabeth, eldest daughter of Edward IV. See also GREAT BRITAIN AND NORTHERN IRELAND, UNITED KINGDOM OF-21. *History* (Later Middle Ages): Wars of the Roses; ROSES, WARS OF THE; YORK, DUKES OF.

YORK AND ALBANY, DUKE OF (FREDERICK AUGUSTUS), British general: b. London, England, Aug. 16, 1763; d. there, Jan. 5, 1827. Second son of George III of England, he was created duke of York and Albany in 1784, shortly after becoming a lieutenant general in the British Army. His career as a field commander from 1793 to 1795, when he had to contain the French in the Low Countries, included a brilliant victory at Beaumont (1794), but in general he failed because his allies were unreliable. He was commander in chief in Great Britain and Ireland from 1801 until his death, except for two years: he resigned in 1809 after it was proved that his mistress, Mary Anne Clarke, had taken bribes to influence him to promote certain officers, but his own integrity was not questioned, and he was reinstated in 1811. In conducting the home defense he redeemed whatever errors he had made in the field. By 1814 he had created an army that was second to none, and competent authorities have pronounced him the ablest administrator in the history of the British Army.

WALLACE BROCKWAY.

YORK CATHEDRAL (known as YORK MINSTER), the Cathedral Church of St. Peter, England's largest medieval cathedral, in York. A wooden building, erected for the baptism of Edwin, king of Northumbria, on Easter Day 627, was followed by three other structures before the present one was begun in 1220. The octagonal chapter house was completed in 1330, the unusually wide and lofty nave in 1345, the choir in 1405, and the massive central tower in 1430. The stately twin

towers were added between 1433 and 1473. York Minster has a magnificent 14th century English Gothic front and is famous for the finest display of medieval colored glass in England, especially the great 15th century east window and the striking 13th century "Five Sisters" in the north transept.

H. GORDON STOKES.

YORKSHIRE, yôrk'shîr, county, England, in the northern part of the country, extending west from the North Sea to within a few miles of the Irish Sea, and southward from County Durham and Westmorland to Derbyshire, Nottinghamshire, and Lincolnshire. England's largest county (6,091 square miles), it is divided for administrative purposes into three "ridings" (thirdings), North, East, and West, of which the last is the largest and includes the main industrial area. The ridings meet near the city of York, which is, however, not in a riding but in the small district of Ainsty. York is the traditional county town, but each of the ridings has its own administrative headquarters: Beverley (East Riding); Northallerton (North Riding); Wakefield (West Riding).

The western boundaries of Yorkshire lie along the flank of the Pennine Chain; Mickel Fell (2,591 feet) is the highest point. North and northeast are the Cleveland and Hambleton Hills and the extensive Yorkshire Moors. The central part of the east coast comprises high chalk cliffs, which fall away north from Whitby to the mouth of the Tees River, and south from Flamborough to Spurn Head, along a shore much subject to erosion. Curving south and southwest from Flamborough is the chalk upland of the Yorkshire Wolds.

The river Ribble flows west to the Irish Sea; all others flow east or southeast to converge on the wide estuary known as the Humber, where Goole is a busy transshipment point between the inland waterways and the important seaport of Hull. Sheep are bred on the higher ground; elsewhere oats, barley, wheat, and sugar beet are grown, and there is stockraising and milk production.

The dales, in the west, contain some of England's most beautiful medieval abbeys: Fountains, Bolton, and Rievaulx. Scarborough, Bridlington, Filey, Whitby, Saltburn, and Redcar are popular resorts on the east coast; Harrogate, 20

Medieval abbeys and old towns like Malham are tourist attractions in Yorkshire.

British Travel Association

miles west of York, is a well-known spa.

Leeds is the most important industrial city, with a wide range of industries but basically a textile town, like Bradford, Halifax, and Huddersfield, born of the former abundance of local wool and the availability of water. Coal and metallurgical industries predominate in southern towns like Doncaster, Rotherham, and above all Sheffield. Middlesbrough, in the north, was founded on the hematite ore formerly abundant in the Cleveland Hills, but most of the ore for the county's industries is now imported. Population: (1961) 4,725,976.

H. GORDON STOKES,
Author of "English Place-Names."

YORKSHIRE TERRIER, a long-coated toy terrier, introduced into the United States about 1880 and first recognized by the Kennel Club in England in 1886. It is closely related to the Skye terrier, perhaps with infusions of the old black-and-tan terrier. The breed has a compact body, short legs, upright carriage, and a distinctive straight silky coat sometimes reaching the ground. The head is small and flat, ears are V-shaped, semi-erect or erect, the body color a dark steel blue, with golden tan on head and chest but not intermingled. With a typical terrier temperament, the dog displays an air of importance and is a fashionable, if not an ancient, breed.

WILLIAM F. BROWN.

YORKTON, yôrk'ton, city, Saskatchewan, Canada, 100 miles northeast of Regina. It is served by the Canadian Pacific and Canadian National railways and has an airport. The city is the business, cultural, and wholesale distributing center for a large and well-settled agricultural area. Industries include flour milling, a slaughterhouse, an oil refinery, and printing plants. Turkey raising is a profitable commercial pursuit. There are many attractive lake resorts in the area. Yorkton was founded in 1882 by the York Farmers' Colonization Company, from York County, Ontario; the original townsite was to the northeast, on Yorkton Creek. It was incorporated as a village in 1894, as a town in 1900, and as a city in 1928. Population: 15,339.

JOHN H. ARCHER.

YORKTOWN, yôrk'toun, town, Virginia, seat of York County, on the York River, near its mouth on Chesapeake Bay, 11 miles east-southeast of Williamsburg. Portions of the town are included in the Colonial National Historical Park. It was settled as early as 1631, established as a county port in 1691, and the county seat was moved here in 1698. Yorktown was a thriving commercial port until the American Revolution, and the last decisive battle of the war was fought here, ending with the surrender of Gen. Charles Cornwallis on Oct. 19, 1781 (see **YORKTOWN, CAMPAIGN AND SIEGE OF**). Historic landmarks include the Moore House, where the articles of capitulation between Cornwallis and George Washington were negotiated; the Custom House (1706; restored 1929); Grace Church (1697); and the Nelson House, home of Thomas Nelson (q.v.). The elaborate white marble Yorktown Victory Monument, a 95-foot shaft overlooking the York River, commemorating the Revolutionary victory, was authorized by Congress in 1781. In the Civil War, Yorktown was captured (1862) by Gen. George B. McClellan on his drive toward Richmond.

YORKTOWN, Campaign and Siege of, in the American Revolution. On May 22, 1781, when the fate of the American Revolution seemed darkest, Gen. George Washington received word that a French fleet, with troop reinforcements, guns, and supplies, was en route from France to assist him. Adm. Comte Louis de Barras, with part of the fleet, soon arrived at Newport, R.I., the base of French forces in the United States. Early in July the comte de Rochambeau moved his 4,800 French troops from Newport to join Washington's 4,500 in the Hudson Valley. The futility of attacking Gen. Sir Henry Clinton's 17,000 strongly entrenched troops in New York City was apparent, and Washington's eyes turned to the south.

His decision was made for him with the arrival of a message from Adm. Comte François de Grasse, announcing that the remainder of the French Fleet, with 3,000 troops aboard, would leave the West Indies in mid-August for Chesapeake Bay, where it could remain only until mid-October.

Meanwhile Gen. Charles Cornwallis (2d Earl Cornwallis), British commander in the south, had fortified Yorktown, Va., to control the entrance to the York River. Washington quickly ordered the marquis de Lafayette, in Virginia, to block the Yorktown peninsula to prevent the escape of Cornwallis, and gathered his forces for a rapid movement southward. Gen. William Heath, with 2,500 men, was left at West Point, N.Y., to guard the Hudson Valley against Clinton. This was a hazardous venture, since Clinton could easily overwhelm Heath and separate New England from the other colonies. But an American victory was essential to bolster the disheartened patriots, and Washington accepted the risks for the sake of the potential gains.

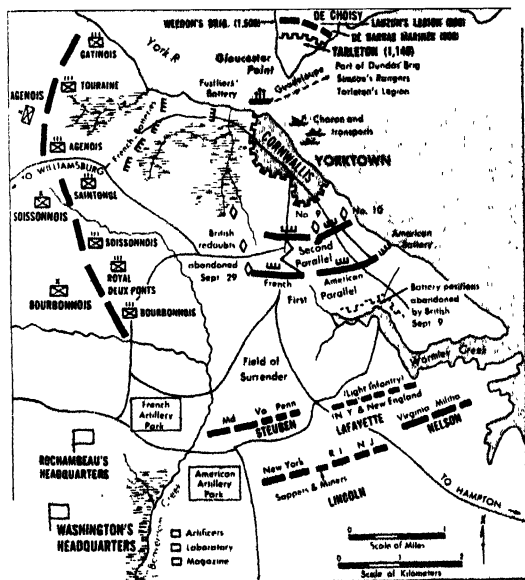

The movement southward was conducted so as to reinforce Clinton's belief that an attack on New York City was contemplated. It was not until Washington's troops had reached Trenton, N.J., that Clinton discerned the true purpose of the march. Immediately he began to organize an expedition to send to the aid of Cornwallis. The combined British fleets of Adm. Sir Thomas Graves and Adm. Sir Samuel Hood were rushed to intercept de Grasse. However, de Grasse reached Chesapeake Bay safely and repulsed the British in a stiff battle. When de Barras with his fleet from Newport joined de Grasse, the British ships fled back to New York.

Washington's leading troops reached Elkton, Md., at the head of Chesapeake Bay, on September 6. On the 18th his army sailed in de Grasse's transports from Elkton, Annapolis, and Baltimore. By the 26th it had joined Lafayette on the Yorktown peninsula in Virginia. Cornwallis had strongly entrenched the land side of Yorktown, augmenting his line with 6 batteries and 7 redoubts. Heavy batteries commanded the sea side of the town, and the British frigates *Guadeloupe* and *Charon*, with several transports, lay off the coast.

Across the river, a detachment had entrenched Gloucester Point, Va. In addition, Cornwallis had constructed an outer line of redoubts and batteries. When he learned that Clinton was sending relief, he abandoned most of these, believing that he could make a stronger defense for the short time necessary with his forces concentrated at Yorktown.

Washington's troops took positions as shown

on the accompanying sketch. Detachments occupied the abandoned enemy works, and artillery was started from Williamsburg, Va., toward the front. On October 6, under heavy British gunfire, the digging of the first parallel, 600 yards from the British lines, was begun; the Americans worked on the eastern portion, and the French on the western. That night troops of the French Régiment Touraine attacked the Fusiliers' Redoubt but were repulsed. On the 9th the French battery (10 guns) on the coast opened fire and drove the *Guadeloupe* away. On that day also Washington personally fired the first shot from the American battery (12 guns) on the coast. The next day a French battery (12 guns) and an American battery (6 guns), positioned at the parallel, joined in the bombardment. French red-hot shot set the *Charon* and two transports afire, causing their destruction. On the night of the 11th, Baron Friedrich Wilhelm von Steuben's division began construction of the second parallel, only 300 yards from the British defenses. Before this parallel could be extended to the east, British redoubts nos. 9 and 10 had to be reduced. On the 14th a detachment from the Catinos and Royal Deux-Ponts regiments, under Col. Guillaume de Deux-Ponts, stormed and captured Redoubt No. 9 in heavy fighting. Simultaneously, an American detachment of New York and New England light infantry troops, under Lt. Col. Alexander Hamilton, charged Redoubt No. 10 with the bayonet and carried it quickly. The second parallel was then extended to include the two captured redoubts.

A British sortie on October 16, by a detachment under Lt. Col. Robert Abercrombie, succeeded in disabling 7 guns of a French and an American battery on the second parallel, but the British were driven back and the guns quickly put in order. Cornwallis then sought to save his army by a movement across the river to Gloucester Point, where he could overwhelm the marquis de Choisy's small force and thence march to New York to join Clinton. By midnight most of the Guards and some other troops were set ashore at Gloucester Point, but a sudden

storm broke, driving the boats upstream. The boats, with the troops that they had carried to Gloucester, returned the next day, but too late. That morning all of the Allied artillery opened a furious cannonade, shattering the British defenses and silencing their artillery. His lines ripe for an Allied assault, Cornwallis offered to capitulate. The surrender, which closed what proved to be the decisive battle of the entire war, was completed on October 19, the same day the British relief expedition sailed from New York.

Cornwallis surrendered 7,157 troops (including sick and wounded not engaged) and 840 sailors, together with 244 artillery pieces. Losses on both sides were light: British and Hessian, 156 killed and 326 wounded; French, 52 killed and 134 wounded; American, 20 killed and 56 wounded.

FORCES ENGAGED AT YORKTOWN

American (8,845 men)

Infantry.—Gen. Benjamin Lincoln's Continental division (1,725): Gen. James Clinton's brigade (1st and 2d New York regiments) and Col. Elias Dayton's brigade (1st and 2d New Jersey regiments and the Rhode Island Regiment).

Baron von Steuben's division (1,900): Gen. Anthony Wayne's brigade (1st and 2d Pennsylvania battalions and 1 Virginia battalion) and Gen. Mordecai Gist's brigade (3d and 4th Maryland regiments).

Marquis de Lafayette's light infantry division (1,500), principally troops from New York and the New England states: Gen. Peter Muhlenberg's brigade and Gen. Moses Hazen's brigade (including Hazen's Canadian Regiment).

Gen. Thomas Nelson's Virginia Militia (3,200): the brigades of Gen. Robert Lawson, Gen. Edward Stevens, and Gen. George Weedon, and Lt. Col. Charles Dabney's Virginia State Regiment.

Artillery.—Col. John Lamb's 2d Continental Artillery Regiment and two companies of the 1st and 5th regiments (310).

Cavalry.—Col. Stephen Moylan's 4th Dragoons and Col. Charles Armand's Legion (100).

Sappers and Miners.—(110).

French (7,800 men)

Infantry.—General de Saint-Simon's Brigade Agenois (3,000): Colonel d'Autiham's Régiment Agenois, Colonel de Rastaing's Régiment Gâtinais, and Colonel de Pondeaux's Régiment Touraine.

Vicomte de Vioménil's Brigade Soissonnais (1,800): Colonel de Saint-Maime's Régiment Soissonnais and Colonel de Custine's Régiment Saintonge.

Baron de Vioménil's Brigade Bourbonnais (1,800): Colonel de Laval's Régiment Bourbonnais and Colonel des Deux-Ponts's Régiment Royal Deux-Ponts.

Cavalry.—Duc de Lauzun's Légion (600).

Artillery.—(600).

British (5,965 men)

Infantry.—Gen. Charles O'Hara's Guards brigade (467); Lt. Col. Robert Abercromby's light infantry (600); Col. John Yorke's infantry brigade (900: 17th, 23d, 33d, and 71st regiments); Col. Thomas Dundas's infantry brigade (1,500: 43d, 76th, and 80th regiments); Colonel von Voigt's and Colonel von Seyboth's Ansbach regiments (950); Hessian regiments Prince Héritaire and von Bose (700); jäger detachment (68); and Lt. Col. John Hamilton's North Carolina Tories (114).

Cavalry.—Col. John G. Simcoe's Queen's Rangers and Col. Banastre Tarleton's British Legion (440).

Royal Artillery.—(193)

Pioneers.—(33).

YORKVILLE, yôrk'vîl, a section of New York City in the Borough of Manhattan. It was founded as a village within the city about 1790 in the area south of Harlem from the old Boston Post Road (Third Avenue) to the East River between 79th and 90th streets, and later expanded to include the district bounded by what is now Lexington Avenue and the river between 59th and 96th streets. Yorkville was successively a farming village, an area of fine country estates of wealthy New Yorkers, and a commuting center after 1834, when the New York and Harlem Railroad connected with Prince Street. Later the section became known as a foreign quarter, first German and Irish, and then central European. Points of interest include Gracie Mansion, the residence of the Mayor of New York City, built about 1794 and situated in Carl Schurz Park; the New York Hospital and Cornell University Medical College; and the Rockefeller Institute for Medical Research and Memorial Sloan-Kettering Cancer Center.

YORUBA, yôr'ə-bə, the third largest ethnic group in Nigeria, Africa's most populous nation. About 10,000,000 Yoruba live in Nigeria's Western Region; over 500,000 are in the Northern Region, and there are about 200,000 in Dahomey and Togo, and in eastern Nigeria.

The Yoruba share a common language and cultural base, but were divided politically into independent kingdoms which warred among themselves and with the neighboring Dahomeans and Fulani throughout the 19th century. The slave wars carried large numbers to Brazil and Cuba, where the Yoruba language is still spoken and Yoruba deities are still worshiped.

The economy of the Yoruba is founded on hoe agriculture, trading, and handicrafts. Maize and manioc, introduced by the early Portuguese, and yams are the staple crops. During the 20th century cacao became an important cash crop. It is now Nigeria's most valuable export, and the Yoruba produce over 90 percent of it. Until sterling currency was introduced, cowrie shells were used as money. Women traders buy local produce and resell it for a profit in the large markets, while men formerly controlled trade with neighboring towns.

Even before contact with Europeans, the Yoruba grew cotton and wove cloth, smelted iron and practiced smithery, cast bronze—using the lost-wax (cire-perdue) process—and made glass. Glassmaking and iron smelting are no longer practiced. They dye and appliqué leather, do beadworking and embroidery, and carve wood, bone, ivory, and calabashes; they also formerly carved stone. All these crafts, except weaving, which is practiced by both sexes, are the work of men; women do spinning, dyeing and tie-dyeing, basketry and matting, and make pottery. The Yoruba produced the greatest wealth of art of any African people, and the ancient bronze castings found at the Yoruba city of Ife rank among the art masterpieces of the world.

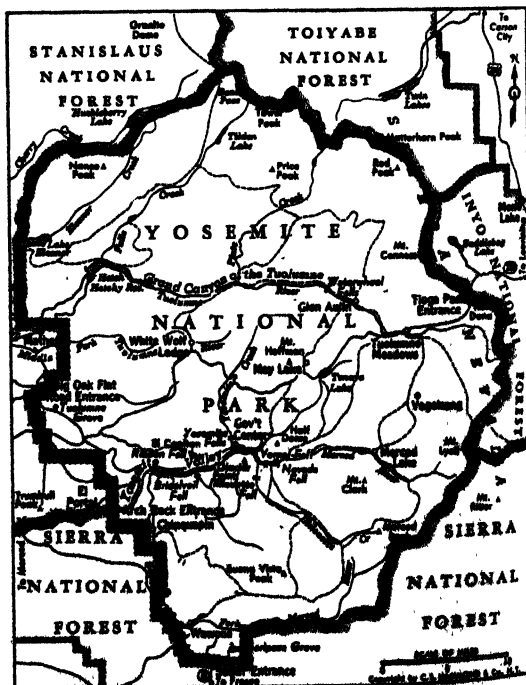

The Yoruba tradition of urbanism antedates European contact, and they are the most urban of African peoples. Nearly a third (31 percent) live in 12 communities of over 40,000 in population, while 22 percent live in 6 cities of over 100,000, of which Ibadan, with over 600,000 people, is the largest.

WILLIAM BASCOM
University of California, Berkeley

YOSEMITE NATIONAL PARK, yô-sēm'ə-tē, national park, California, embracing a spectacular mountain region about 150 miles east of San Francisco, on the western slope of the central Sierra Nevada. The park comprises 760,951 acres (1,189 square miles) surrounding the headwaters of the Merced and Tuolumne rivers from the Sierran crest on the east to the foothills of the Mother Lode country on the west. Although the park contains much beautiful scenery in the High Sierra, it was created primarily to preserve the magnificent Yosemite Valley and the Mariposa Grove of rare "Big Trees" (*Sequoia gigantea*).

Scenic Features. Yosemite Valley, called Ahwahnee (deep grassy valley) by the Indians, is a flat-floored, glacially gouged valley about 7 miles long and less than 1 mile wide. On its floor (elevation 3,960 feet) the Merced River meanders placidly through meadows and groves of trees. On either side magnificent granite walls rise almost perpendicularly 2,500 to 3,500 feet from the valley's edge. The promontories and abutments created by glacial and stream erosion and the waterfalls formed when their lower courses were truncated are among the world's best-known scenic wonders. Yosemite Falls, on the north side of the valley behind Yosemite Village, drops 2,610 feet in three stages and is the longest falls in North America; Bridalveil Falls on the south side near the lower entrance to the valley has a sheer drop of 620 feet over a granite cliff. Dominating the lower end of the valley on its north side is El Capitan (7,564 feet), and farther upstream are the Three Brothers (6,860 feet), Yosemite Point (6,935 feet), and the North Dome (7,531 feet) rising high above the Royal Arches. On the south side, Old Inspiration Point (6,603 feet), Cathedral Rocks (6,638 feet), and Glacier Point (7,214 feet) are the dominant features. At the eastern end of the valley between Tenaya

Yosemite National Park

El Capitan and Bridalveil Falls frame the lower end of the 7-mile-long glacially gouged Yosemite Valley.

Creek and the Merced River is the monumental Half Dome (8,852 feet), its flat northern face formed during an earlier stage of erosion.

The floor of the valley contains no sequoia trees, since the climate is not suitable, but there are three groves in the high country within the park. The Mariposa Grove, 36 miles south of Yosemite Village, is the largest, with about 200 mature trees, and the most frequently visited, although the Tuolumne Grove and the Merced Grove are both accessible by road north of the valley. Many of the giant sequoia have attained a height of 250 feet, a girth of 30 feet, and an age of 3,500 years, but their size and age have been stressed to the detriment of their superb form.

Geology. Prior to the last glacial age, which ended some 10,000 years ago, the Merced River and its tributaries had cut deep narrow canyons into the granite of which the Sierras are formed. Above the gently rolling lands between the canyons there were numerous "domes" of bare granite almost hemispheric in shape. Glaciers flowed down the canyons of both the Merced and the Tenaya, its main tributary, joining just west of Half Dome. The enlarged river of ice, estimated to have been more than 3,000 feet thick, deepened the lower canyon about 1,200 feet, widened it in the characteristic U shape by 3,500 feet, and created the almost vertical walls present today. The terminal moraine at the end of the glacier's advance formed a dam and created a long narrow lake about 300 feet deep. The lake gradually filled as rock fragments were washed in by the rivers and streams, leaving the almost level lake plain over which the Merced River meanders.

History. Yosemite Valley was not discovered until 1851 when Maj. James D. Savage, leading

Cathedral Rocks, on the southern side of the valley, rise to heights of more than 6,600 feet.

AL LOWRY, FROM PHOTO RESEARCHERS

the Mariposa Battalion in pursuit of a band of Indians who had been raiding mining camps in the Mother Lode, traced them to the valley, which was their home. The Indians were of the Miwok tribe but were called the Yosemite (Miwok for "grizzly bear") after their clan totem; and Lafayette H. Bunuel, who accompanied the battalion, suggested that the euphonious name of the clan be given to the valley. The Yosemite were the most warlike clan of the Miwok, and perhaps for that reason they were able to keep the valley for themselves. In the Indian pattern of living, this was a rich area, far better than the high country on either side. The main portion of the diet was acorns, which grew in profusion on the oaks of the valley floor; in addition, there was a variety of game animals, fish, grass seeds, and other vegetable foods. Although there was much snow in the winter in the surrounding high country, the climate of the valley floor was not too severe. There were about 22 Indian villages in the valley when it was discovered.

As early as 1855 visitors began to arrive in the valley, and their descriptions of its magnificence attracted an increasing number of tourists despite the rugged trip. To preserve the beauties of Yosemite, Congress in 1864 made a special grant of 48.6 square miles of the area to California for a state park, including not only the valley but also the Mariposa Grove. In 1890 the Yosemite National Park was established surrounding the state park. Separate administrations caused difficulty, and in 1906 the state ceded its park back to federal control. Although, since its beginning, control of the national park has been vested in the secretary of the interior, the United States Army operated it until 1916, when the National Park Service was created.

Facilities. For many years the only access to the park was by horseback or stagecoach descending over steep trails or poor roads from the north and south. Then, in 1926 a road was con-

structed up the steep and narrow Merced Canyon below the valley, and there are now three good automobile highways. A magnificent set of trails has been constructed by the National Park Service, making the back country to the east, north, and south accessible to hikers and pack trains.

Numerous camping sites have been provided in the valley itself and along the trails in the high country, and there is a fine museum in Yosemite Village. In addition, facilities ranging from housekeeping cabins to excellent hotels are available. Many of these facilities are open on a year-round basis to provide for winter sports.

JOHN W. REITH

Associate Professor of Geography, University of Southern California.

YOSHIDA, yō-shē-dā, **Shigeru**, Japanese statesman: b. Tokyo, Japan, Sept. 22, 1878; d. Oisi, Japan, Oct. 20, 1967. He was the son of Tsuna Takeuchi, but he was adopted by Kenzo Yoshida and married the daughter of the statesman Count Nobuaki Makino. After graduating from Tokyo Imperial University in 1906, Yoshida promptly entered the foreign service. During the period when Japan was establishing hegemony in Manchuria, he held the key positions of consul general in Tientsin (1922-1925) and Mukden (1925-1928) and vice foreign minister (1928-1930) in the cabinet of Gi ichi Tanaka and his successor. His last official position before World War II was ambassador to Britain (1936-1939).

Despite his close ties with the bureaucracy, the *zaibatsu* (financial cliques), and court circles, Yoshida was imprisoned (June-August 1945) for activities against the former prime minister, Hideki Tojo, in favor of peace. After Japan's surrender, he was appointed foreign minister in the cabinets of Naruhiko Higashikuni (1945) and Kijuro Shidehara (1946). When Ichiro Hatoyama was purged from politics by the American occupation authorities, Yoshida became leader of the Liberal Party and formed his first cabinet in 1946. From 1948 to 1954 he served continuously as prime minister, a record in Japanese history. With the support of the occupation authorities he exercised near-dictatorial powers to adopt the new Constitution (1947), to effect land reform, to sign the peace treaty at San Francisco (Sept. 8, 1951), and to negotiate the first mutual security pact with the United States.

ARDATH W. BURKS

Professor of Political Science, Rutgers—The State University, New Brunswick, N.J.

YOSHIMASA, yō-shē-mā-sā (in full YOSHIMASA ASHIKAGA), Japanese shogun: b. 1436; d. 1490. He was the grandson of Yoshimitsu and 8th in the line of Ashikaga shoguns. His rule (1443-1473) was marred by a deterioration of shogunal authority, general economic distress, and lengthy civil war. Yoshimasa himself was more inclined to aesthetic pastimes than to the affairs of government. He is said to have permitted the issuance of 13 debt cancellation (*tokusei*) edicts in an effort to ameliorate the financial distress of the military class. Such measures only served to throw commercial activities into confusion and did little to stem the tide of city riots and peasant uprisings. Yoshimasa's choice of heir precipitated the destructive Onin War (1467-1477), which was fought in the streets and environs of Kyoto, the capital city. Meanwhile he retired to

his newly built Silver Pavilion (Ginkaku) in the eastern hills (Higashiyama) of Kyoto, where he patronized a coterie of artists, actors, and Zen priests. This group is credited with advancing the art forms of the tea ceremony and *no* (Jap. *nō*) drama and setting Japanese taste in ceramics, painting, and architecture for many centuries to come, in what is called the Higashiyama period of artistic development.

JOHN W. HALL, *Yale University*

YOSHIMITSU, yō-shē-mē-tsōō (in full YOSHIMITSU ASHIKAGA), Japanese shogun: b. 1358; d. 1408. He was the 3d shogun in the Ashikaga line, which reached its zenith under his shogunate (1367-1395). With the aid of his deputy, Yoriyuki Hosokawa, Yoshimitsu forced his most turbulent vassals, the Yamana and Ouchi, into submission and brought an end (1392) to the civil war that had raged throughout the country in the name of the rivalry between the north and south imperial courts. Having established his seat of authority at Muromachi in Kyoto, Yoshimitsu ruled with great pomp, taking the highest of court titles and even aspiring to imperial status. Under him the administrative structure of the Ashikaga shogunate took its final shape. Yoshimitsu retired from office in 1395 but continued to direct Ashikaga policy. In 1397 he built the famous Golden Pavilion (Kinkaku), a villa on the outskirts of Kyoto, at which he entertained.

YOSHIMUNE, yō-shē-mōō-nē (in full YOSHIMUNE TOKUGAWA), Japanese shogun: b. 1684; d. 1751. Eighth of the Tokugawa line, he was the third son of Mitsusada Tokugawa, daimyo of Kii. Yoshimune became lord of Kii in 1705 but was called to succeed to the main Tokugawa line in 1716 and continued to hold the shogunate until his retirement in 1745. He was one of the few shoguns after Ieyasu, founder of the Tokugawa line, to exercise personal influence on shogunal policy. Faced by financial weakness in the shogunate and general economic deterioration of the warrior class, he conducted a vigorous reform of government and fiscal policy, known as the Kyōko reform. Yoshimune reduced shogunal expenditures and reissued the country's gold currency, reversing the debasement policy of his predecessors. Though conservative in his domestic policies, in 1720 he lifted the ban on the importation of Western books in order to bring in technical knowledge. He ordered a revision of the calendar and encouraged land reclamation, the spread of sericulture, and the cultivation of such new crops as the sweet potato. Yoshimune's policies were a momentary success, but in the main they affected the symptoms and not the root of the problems faced by the Tokugawa government.

JOHN W. HALL, *Yale University*

YOSHITSUNE, yō-shē-tsōō-nē (in full YOSHITSUNE MINAMOTO), Japanese warrior: b. 1159; d. 1189. The son of Yoshitomo and younger half-brother of Yoritomo, he was exiled to a monastery after the victory of the Taira clan over his own in 1160. In 1180, on hearing that Yoritomo had begun an attack on the Taira, Yoshitsune raised a following, joined other members of his clan, and quickly distinguished himself for his gallantry and bold strategy. He is best known for brilliant victories over members of the Taira clan at Ichino-tani, Yashima, and Dan-no-ura (1185). Re-

turning in triumph to the capital, he received favors from ex-emperor Go-Shirakawa and thereby incurred the mistrust of Yoritomo. Eventually he was frustrated in an attack on Yoritomo and spent the last years of his life as a fugitive from Yoritomo's agents. Tracked down at Hiraizumi in northern Honshu, he committed suicide to avoid capture. Many episodes of his life have been depicted in ballads and classical drama.

JOHN W. HALL.

YOST, yöst, **Fielding Harris**, American football coach: b. Fairview, W.Va., April 30, 1871; d. Ann Arbor, Mich., Aug. 20, 1946. After taking a law degree (1897) at the University of West Virginia, he became head football coach at the University of Michigan (1901-1927). Known as "Hurry Up" Yost, he coached Michigan's famous "point-a-minute" football teams (1901-1905) and devised outstanding blocking and signaling systems. As director of athletics at Michigan from 1921 to 1941, he developed the university's athletic facilities and intramural sports program to meet his ideal of "sports for all." He wrote *Football for Player and Spectator* (1905).

YOU CAN'T GO HOME AGAIN, a novel by Thomas Wolfe that was published posthumously in 1940. It is a continuation of *The Web and the Rock* (1939; see **WEB AND THE ROCK, THE**); together they constitute the second of Wolfe's immensely long fictional autobiographies, the first comprising *Look Homeward, Angel* (1929) and *Of Time and the River* (1935). The hero of the earlier volumes, Eugene Gant, becomes George Webber; either way he is a dramatic projection of Wolfe himself, who was incapable of real objectivity in his novels.

In *You Can't Go Home Again* Wolfe voices his surprise and disappointment at the hostile reception of his first novel in his home town. His isolation is increased when he breaks off his love affair with Esther Jack and takes to writing almost uninterruptedly in a Brooklyn tenement. He is dependent upon his editor and friend Foxhall Edwards (a transparent disguise for Maxwell E. Perkins of Scribner's), whom he later rejects to assert his independence as a writer. In England he meets Lloyd McIlarg (actually Sinclair Lewis), and in Germany he enjoys fame and fortune; but he returns to America despondent about the future as war clouds gather over Europe. This novel, Wolfe's last, stands firmly on a level with his other three major works.

DELANCEY FERGUSON.

YOUNG, Vincent, American composer of light music: b. New York, N.Y., Sept. 27, 1898; d. Denver, Colo., April 5, 1946. Although he showed prodigious musical talent as a child and was given serious training, he at first meant to become an engineer and then worked briefly in Wall Street. While in the United States Navy during World War I, he was in the entertainment unit at Great Lakes Naval Training Station. In 1918 he joined a New York publisher of popular sheet music. His first musical comedy, *Two Little Girls in Blue* (with lyrics by Ira Gershwin) was staged in New York in 1921; it was followed, among others, by *Wildflower* (1923), *No, No, Nanette* (1924), *Oh, Please* (1926), *Hit the Deck* (1927), and *Great Day* (1929), some of them composed with others. He also wrote the hit score for the motion picture *Flying Down to Rio*

(1933); shortly thereafter he was incapacitated by tuberculosis, from which he died after necessarily idle years spent in New Orleans and Denver. A number of his songs remain in the permanent repertoire, among them *Bambalina*, *The Carioca*, *Great Day*, *Hallelujah*, *I Want to Be Happy*, *Rise 'n' Shine*, *Sometimes I'm Happy*, *Tea for Two*, *Time on My Hands*, and *Without a Song*.

HERBERT WEINSTOCK.

YOUNG, Andrew (1932-), American public official and former ambassador to the United Nations. Andrew Jackson Young, Jr., was born in New Orleans, La., on March 12, 1932. Intending to become a dentist, like his father, he attended Howard University (B.S., 1951) but then decided to enter the ministry and went on to Hartford (Conn.) Theological Seminary (B.D., 1955). He was ordained in the United Church of Christ and held pastorships in Alabama and Georgia.

While he was working with a voter registration project for the United Church of Christ, he collaborated with Dr. Martin Luther King, Jr. Subsequently he joined the Southern Christian Leadership Conference (SCLC), becoming executive director in 1964 and, after Dr. King's death, executive vice president under the Rev. Ralph Abernathy. He was active also in antisegregation campaigns in Birmingham, Ala., and Chicago and in the 1968 antipoverty march on Washington, D.C.

In 1970, Young ran unsuccessfully for Congress in Georgia's 5th district, but he won in a second try in 1972 and was reelected in 1974 and 1976. An adviser to Jimmy Carter during Carter's 1970 bid for the Georgia governorship and again during the 1976 presidential campaign, Young was named ambassador to the United Nations by Carter in December 1976 and was sworn in on Jan. 30, 1977.

Young's assignments as ambassador included fact-finding missions to Africa and tours of Caribbean and Latin American countries. He aroused criticism because of his frank and often caustic expressions of opinion, and occasionally his statements were repudiated by the State Department. On Aug. 16, 1979, after an unauthorized meeting with a Palestine Liberation Organization representative, he resigned his UN post. He was elected mayor of Atlanta in 1981 and reelected in 1985. Barred by law from seeking a third term as mayor, he ran for the governorship of Georgia in 1990 but was defeated in a runoff election for the Democratic nomination.

YOUNG, yung, Arthur, English agricultural writer: b. London, England, Sept. 11, 1741, d. there, April 20, 1820. His family were gentry from Bradfield Combust, Suffolk, where he spent much of his life. He was intended for a mercantile career and also tried journalism for a time, but in 1763 he became a farmer and practiced agriculture for the remainder of his life.

Although never financially successful as a farmer, Young became the outstanding publicist for the agricultural revolution. He first gained recognition through the nine volumes on his three agricultural tours of England, which he made from 1768 to 1771. The *Tour in Ireland* appeared in 1780. His *French Travels During the Years 1787, 1788, and 1789* (1792) was his most famous work and still remains a valuable primary source for the background of the French

Revolution. Young was primarily interested in crops, livestock, and agricultural methods and improvements, but he also described agrarian classes, tenures, roads, inns, trade, and manufactures. At its best, his journalistic style was sprightly and vivid. Some of his books were translated into French, Russian, and German, and he carried on a wide correspondence with famous people, including George Washington and the marquis de Lafayette.

In 1784 he began the periodical, *Annals of Agriculture*, which appeared continuously until 1809 and ran to volumes, of which he wrote about a third. Among his contributors was George III, who wrote under the name of Ralph Robinson, his Windsor shepherd. In 1793 Young was appointed secretary to the newly created Board of Agriculture, a post he held until his death. He also served actively for many years in the Society of Arts.

Although Young himself contributed little to scientific agriculture, he was always its inspired publicist, explaining and supporting such advances as the seed drill and horse hoe, improved crop rotations using root crops to eliminate fallows, and better stockbreeding methods. As spokesman for the nobility and gentry, he backed the corn laws, attacked tithes and poor rates, and supported enclosures until very late in his life. His early writings were strongly mercantilist, but later he favored some laissez-faire doctrines. Until 1792 he was fairly liberal, but the excesses of the French Revolution made him very conservative, as is shown in *The Example of France a Warning to Britain* (1793). Following the death of his favorite daughter in 1797, Young experienced a deep religious conversion and became a fervent Evangelical. He was blind in his last years.

JOHN G. GAZLEY
Professor of History
Dartmouth College

YOUNG, Brigham, Mormon leader: b. Whitingham, Vt., June 1, 1801; d. Salt Lake City, Utah, Aug. 29, 1877. He was the ninth of 11 children of John and Abigail (Howe) Young. When he was three years old, his indigent family moved to a region of upstate New York called the "burnt-over district" for its excesses of religious enthusiasm. Brigham grew up, practically without formal education, to become a journeyman painter and glazier. In 1829, he moved to Mendon, New York, and in 1832, after pondering the *Book of Mormon* for two years, he left the Methodists, whom he had joined at the age of 22. He followed several members of his family into the Mormon Church, in whose ranks he steadily rose to importance.

Young was appointed an apostle in the Mormon Church in 1835 and carried out missionary work in the Eastern states and, from 1839 to 1841, in England as head of the most fruitful of the Mormon missions. It was here that he first published the *Millennial Star*.

In 1834, he had accompanied Zion's Camp to Missouri to aid the beleaguered Saints, and in 1838-1839, when the Mormons were driven from that state, he organized their exodus. After the murder of Joseph Smith by mob violence in 1844, Young stepped into the leadership of the stricken and harassed people about to be driven for the fourth time from their place of settlement. Despite disorganization, fierce opposition, and

great physical hardship, he brought them across Iowa to Winter Quarters, Nebr. in 1846 and prepared them for the westward trek to Utah, having meanwhile (1844) defeated Sidney Rigdon (q.v.) for the post of church leader.

Brigham Young

The Bettmann Archive

Young sought aid from the United States government, which equipped the Mormon Battalion for a march to California as part of its operations in the Mexican War; and, to determine a place of settlement, he studied literature from government and other sources and interviewed travelers. In 1847 he led a party of 148 to the valley of the Great Salt Lake, arriving himself on July 24. On his return to Winter Quarters, he was formally elected church president.

In Utah, Young planned settlements, "calling" the settlers to a religious duty and choosing them according to needed skills. Young was appointed governor of the Territory of Utah in 1850 and again in 1854. He organized emigration from the East and brought some 70,000 persons from Europe, a success marred only by the disaster at Sweetwater River, Wyo., in October 1856, when a group of settlers traveling on foot and pushing heavy handcarts died in a snowstorm. He encouraged farming and indigenous industry, strengthening the Mormon community, but giving non-Mormons control of Utah's mineral wealth. He built canals, established cooperative irrigation and retail store enterprises, and later revived the cooperative United Order communities. Each community differed—the most extreme involving complete community living as one large cooperative family, the least involving a part-time cooperative farm or business. He also developed church-owned business interests and sponsored educational institutions, including the University of Deseret (1850), now the University of Utah.

Although not appointed governor again in 1858, Young withstood federal opposition and remained the effective authority in Utah regardless of who held the gubernatorial office. He took advantage of the coming of the railroad in 1869, a development intended to bring his downfall. Dealing sternly with dissent, he maintained his leadership over the theocratic community that he had built, with the assistance of such able lieutenants as Heber C. Kimball, Wilford Woodruff, and George Q. Cannon.

Young preached and practiced plural marriage and had 27 wives and 56 children. On his death, Utah's Mormon population had reached 140,000, comprising a widespread and distinctive community, which had survived the rigors of

settlement and of opposition that had broken out into violence in the Utah Mormon War of 1857.

YOUNG, Cy (1867–1955), American baseball pitcher, who won the most games in major league history. The annual awards for best pitcher, established in 1956, are named in his honor. Over 22 seasons, he won 511 games and lost a record 313. His 906 games pitched were a record until 1968, and his 7,377 innings remain a record. He won 20 or more games in 14 consecutive seasons and topped 30 wins five times. He also pitched three no-hitters, including a perfect game (against Philadelphia) in 1904.

Denton True Young was born in Gilmore, Ohio, on May 29, 1867. A farmer, he did not become a professional player until he was 23. He was dubbed "Cy," short for "cyclone," which described the velocity of his fastball.

After 11 National League seasons with Cleveland and St. Louis, he jumped to Boston of the newly formed American League and became its first pitching star. In the first World Series (1903), he defeated Pittsburgh twice as Boston won the championship.

Young's career covered the period during which the pitching mound was moved from 50 feet to 60 feet 6 inches from home plate.

Young was elected to the Baseball Hall of Fame in 1937. He died near Peoli, Ohio, on Nov. 4, 1955.

"Baseball's Best: The Hall of Fame Gallery"

YOUNG, Edward (1683–1765), English poet. He was born in Upham, near Winchester, England, and baptized on July 3, 1683. He attended Winchester College and various colleges at Oxford, receiving degrees in 1714 and 1719. Through Thomas Tickell he gained entrée into London literary circles and began publishing poems dedicated to prominent persons. After considerable legal maneuvering, Young obtained an annuity of £100 from the duke of Wharton. He next turned his talents to drama, producing three so-called tragedies on Oriental themes: *Busiris*, *King of Egypt* (1719), *The Revenge* (1721), and *The Brothers* (not published until 1753). From 1725 to 1728 he wrote a series of seven Horatian satires (*The Universal Passion*), which attacked folly in society. Meanwhile, hoping for quicker advancement, Young had turned to the church. After taking orders he was appointed chaplain to George II in 1728 and two years later was named rector of Welwyn. In 1731 he married Lady Elizabeth Lee and settled into a leisurely life of retirement, spent in writing poetry and entertaining prominent friends.

Young's best-known work, *The Complaint, or Night Thoughts on Life, Death, and Immortality*, appeared from 1742 to 1745. The poem, composed originally of four "Nights" or cantos in blank verse, combines a justification of Christian doctrine with autobiographical suggestions, strong macabre and sensational detail, and pious but conventional moral reflections. These ele-

Cy Young set a big-league mark with 511 career victories.

ments are strung together on a slight thread of narrative (actually more character contrast than narrative). Lorenzo is a man of the world whose life of pleasure, which ill prepares him for death and the afterlife, is contrasted with the sudden death of Philander, a good man, and the death of the virtuous Narcissa in her youth. This sentimental and pious strain made the first four "Nights" a success. The last five sections are almost purely theological and were less popular. Few if any mid-18th century poems were more influential than *Night Thoughts*, not only in England but in France and Germany as well. The poem's melancholy, sentimentalism, preoccupation with death, and personal emotion marked its affinity with the growing romanticism of the period.

In 1759, Young wrote for a friend, the novelist Samuel Richardson, *Conjectures on Original Composition*, a piece of literary criticism that defended the romantic view of genius as extravagant, subjective, and nonimitative. This work and *Night Thoughts* placed Young as a forerunner of the romantic movement, a place that he still occupies in literary history. He died at Welwyn, Hertfordshire, on April 5, 1765.

DONALD B. CLARK
Author of "Alexander Pope"

YOUNG, Ella (1867–1956), Irish author. She was born in Fenagh, County Antrim, Ireland, on Dec. 26, 1867. She moved to southern Ireland during her early childhood and became associated with the Irish literary revival in Dublin. She went to America as a lecturer in 1925, held a lectureship on Celtic literature and mythology at the University of California, and continued to live on the west coast. She died in Oceano, Calif., on July 23, 1956.

Something of a recluse, she published several

volumes of verse, prose sketches, and tales based largely upon Celtic mythology, and the autobiographical *Flowering Dusk* (1945). Much of her verse and prose creates a mysterious world of fantasy.

WILLIAM BRACY.

YOUNG, Ella Flagg, American educator: b. Buffalo, N.Y., Jan. 15, 1845; d. Washington, D.C., Oct. 26, 1918. She was educated at the Chicago Normal School and later studied under John Dewey, receiving her Ph.D. from the University of Chicago in 1900. She had begun to teach in 1862 and in 1868 was married to William Young, who died the next year. Mrs. Young was appointed a district superintendent of schools in Chicago in 1887, and in 1899 she became professor of education at the University of Chicago. She served as principal of the Chicago Normal School from 1905 to 1909 and then became superintendent of Chicago's public school system, from which she retired in 1915.

As a pioneer of the Dewey school in progressive education, Mrs. Young underscored the importance of concrete experience in the learning process and advocated the greatest possible personal liberty for students consistent with a sense of responsibility. She was also active in social work, with Jane Addams, and in the woman suffrage movement, and was the first woman president of the National Education Association (1910-1911). She published *Isolation in the School* (1900), *Ethics in the School* (1902), and *Some Types of Modern Educational Theory* (1902).

YOUNG, Ewing, American trapper, explorer, and frontiersman: b. Jonesboro, Tenn., before 1794; d. Willamette Valley, near present Newberg, Oreg., February 1841. He was the son of Charles Young, veteran of the Battle of King's Mountain in the American Revolution, and Mary Rebecca Wilkins. His early trade was carpentry. In partnership with William Becknell he took the first wagon train (four wagons) over the Santa Fe Trail from Franklin, Mo., to New Mexico in 1822—the first of seven such trips that he made over the trail in as many years.

Making Taos, New Mexico, his headquarters, he became the central figure in the Southwest fur trade, sending and leading trapping parties into the Colorado River watershed. Young also drove mules and mule stock (jacks) back over the trail to Missouri and thus played a significant part in that state's growing mule industry, which prospered because of the expanding cotton and sugar farming down the Mississippi River.

In 1829-1830 Young opened the Gila Trail, sometimes called the Ewing Young Trail, through the Southwestern plateaus and deserts to southern California. On this trip he had with him a young man, Christopher (Kit) Carson, on his first extensive trapping excursion. Young trapped the California valleys until 1834, when he led a party north to the Willamette Valley of Oregon. There he settled in the Chehalem Valley, 30 miles southwest of present Portland, and raised livestock, farmed, operated a sawmill, and ran a trading post. In 1837 he led a drive of 800 Spanish cattle north from San Francisco Bay to Oregon, reaching the Willamette Valley settlement with 630 head of much-needed livestock. His death compelled the settlers to form the first organized

government in Oregon, with the offices of probate judge, sheriff, and clerk, to probate his extensive estate.

KENNETH L. HOLMES,
Associate Professor of History, Linfield College,
Oregon.

YOUNG, Francis Brett, English novelist and poet: b. Halesowen, Worcestershire, England, 1884; d. Cape Town, South Africa, March 28, 1954. He studied medicine at the University of Birmingham and practiced in England until World War I, when he served as an army medical officer in East Africa. In the meantime he had published volumes of fiction, poetry, and criticism. *Portrait of Clare* (1927; American title *Love is Enough*) won special critical acclaim and the James Tait Black Memorial Prize. Other books include his horror romance *Cold Harbour* (1924); fictional studies of South Africa such as *They Seek a Country* (1937) and *The City of Gold* (1939); an Italian adventure story of two English spinsters, *A Man About the House* (1942); a long epic poem about the evolution and history of Great Britain, *The Island* (1944); and a descriptive volume, *In South Africa* (1952). His best novels assimilate much of his unusual versatility, exploiting his talents as poet, nature lover, musician, soldier, world traveler, and physician.

WILLIAM BRACY.

YOUNG, Sir John, Baron LISGAR, British political administrator: b. Bombay, India, Aug. 31, 1807; d. Bailieborough, Ireland, Oct. 6, 1876. He graduated from Oxford in 1829, was called to the bar in 1834, and sat in the House of Commons from 1831 to 1855. On the death of his father in 1848 he had succeeded to the baronetcy. Young served as chief secretary for Ireland (1852-1855) and lord high commissioner of the Ionian Islands (1855-1859) and was governor general of New South Wales from 1861 to 1867. In 1869 he was appointed governor general of Canada, where he remained until 1872. For his success in suppressing the Manitoba insurrection of 1869-1870, led by Louis Riel (see *RIEL'S RISINGS—The Manitoba Insurrection*), Young was rewarded with the title of Baron Lisgar.

YOUNG, John Russell, American journalist: b. Tyrone County, Ireland, Nov. 20, 1840; d. Washington, D.C., Jan. 17, 1899. He was brought to the United States as an infant by his parents and grew up in Philadelphia and New Orleans. In 1857 he became a copy boy on the *Philadelphia Press* and soon was a reporter. His coverage of the First Battle of Bull Run (July 1861) brought him national attention, and in 1862 he was made managing editor of the *Press*. Thereafter he was managing editor of the *New York Tribune* (1866-1869) and European correspondent of the *New York Herald* (from 1872), in which capacity he accompanied former President Ulysses S. Grant around the world in 1877-1879. When Chester A. Arthur succeeded to the presidency, Grant recommended Young for the post of minister to China, where he served from 1882 to 1885 and played a significant role in the negotiations that led to the French protectorate over Indochina. He was librarian of Congress from 1897 until his death. Young wrote *Around the World with General Grant* (2 vols., 1879); his *Men and Memories: Personal Reminiscences* (2 vols., 1901)

was edited by his widow, May D. Russell Young.

YOUNG, Loretta (originally **GRETCHEN YOUNG**), American motion picture and television actress: b. Salt Lake City, Utah, Jan. 6, 1913. She moved to Hollywood with her mother at the age of four and began to appear briefly in silent films a year later. Her career began seriously in 1927, when she won a small part in the silent picture *Naughty But Nice*. Thereafter she played leading roles in nearly 100 motion pictures, with Warner Brothers (1927-1934), Twentieth Century-Fox (1934-1940), and as a free-lance star from 1940. In 1948 she received the Academy Award for her performance in *The Farmer's Daughter*. She subsequently became one of America's favorite television actresses in the *Loretta Young Show*, which won several television Academy awards.

YOUNG, Mahonri (Mackintosh), American sculptor, painter, and etcher: b. Salt Lake City, Utah, Aug. 9, 1877; d. Norwalk, Conn., Nov. 2, 1957. A grandson of Brigham Young, the Mormon leader, he studied at the Art Students League in New York City and the Julian Academy in Paris, and subsequently taught for many years at the Art Students League. Young is widely known for his simple and realistic bronzes of workmen and prizefighters and his etchings of city scenes. The Sea Gull Monument to the Mormon leaders in Salt Lake City and a statue of his grandfather in the Capitol in Washington, D.C., are among his major works. He also modeled the Hopi and Apache Indian groups for The American Museum of Natural History in New York City.

YOUNG, Owen D., American lawyer, industrial executive, and statesman: b. Van Hornesville, Herkimer County, N.Y., Oct. 27, 1874; d. St. Augustine, Fla., July 11, 1962. He graduated from St. Lawrence University, in Canton, N.Y., in 1894 and from Boston University Law School in 1896. He then practiced law in Boston until 1912 and lectured at Boston University Law School until 1903. After fighting a case against a General Electric subsidiary in 1912, Young was invited to become general counsel of the General Electric Company in 1913 and eventually was chairman of the board (1922-1939, 1942-1944). Meanwhile, at President Woodrow Wilson's request, he had organized the Radio Corporation of America in 1919 to strengthen the position of the United States in international communications, serving as chairman of its board until 1929 and chairman of the executive committee until 1933. Young was also a director of the Federal Reserve Bank of New York (1923-1940) and of many large corporations, and a trustee of a number of leading educational institutions.

Young's greatest distinction was his service as an international statesman, especially in the liquidation of financial problems after World War I. He was coauthor with Vice President Charles G. Dawes of the so-called Dawes Plan, which fixed the amount and method of payment of German reparations at the London Reparations Conference of 1924; and as conciliator at the London Conference of Premiers that followed, he was credited with being the major influence in inducing acceptance of the plan by the Allied governments. Then, at the invitation of the European governments, but without encouragement from the United States, Young presided at the following Paris Reparations Conference in 1929. The

problem of moderating Allied demands by considering Germany's capacity to pay presented great difficulties, and the Young Plan that emerged was hailed at the time as one of the greatest diplomatic triumphs ever attained.

Young was remarkable for his capacity to analyze difficult industrial and political problems, to invent solutions, and to gain acceptance by conciliating opposing points of view. He was also noted for his modesty, illustrated by his refusal to be honored by a great reception planned for him in New York City after the acceptance of the Young Plan. After his retirement in 1939, he engaged in dairy farming in his native town. He had previously donated his collection of rare books and manuscripts, valued at more than \$1 million, to the New York Public Library.

QUINCY WRIGHT,
Professor Emeritus of Foreign Affairs, Woodrow
Wilson Department of Foreign Affairs, Uni-
versity of Virginia.

YOUNG, Rida (Johnson), American playwright and musical comedy librettist: b. Baltimore, Md., 1875; d. Stamford, Conn., May 8, 1926. After coming to New York City as an aspiring young playwright, she spent several years as a minor actress and a writer of popular song lyrics for a music publisher before completing her first satisfactory play, *Glorious Betsy*. Her first real success, *Brown of Harvard*, was produced in 1906, followed by *The Boys of Company B* (1907) and *The Lottery Man* (1909). In 1910 she prepared the book and lyrics for Victor Herbert's *Naughty Marietta*. For the popular entertainer Chauncey Olcott she wrote *Barry of Ballymore* (1911), including the words for the popular song, *Mother Machree*. This was followed by *Isle of Dreams* (1912) and *Shameen Dhu* (1913). Later she did the dramatic adaptation for Sigmund Romberg's first great success, *Maytime* (1917); the book and lyrics for Rudolf Friml's *Sometime* (1918); and other librettos. Her comedies *Captain Kidd Junior* and *Her Soldier Boy* were produced in 1916; *Little Old New York*, in 1920.

WILLIAM BRACY.

YOUNG, Robert Ralph, American financier and railway executive: b. Canadian, Texas, Feb. 14, 1897; d. Palm Beach, Fla., Jan. 25, 1958. After engaging in varied business activities through the 1920's, he emerged from the stock market crash of 1929 with a reputed \$1 million, made by selling short, and became a partner in the brokerage firm of Young, Kolbe, and Company in 1932. In 1937, with the backing of financier Allan P. Kirby, he bought heavily into the Alleghany Corporation, a railroad holding company. After a series of legal and financial battles, he took control in 1942, becoming board chairman of Alleghany and one of its assets, the Chesapeake and Ohio Railway Company. Young's vigorous attack on existing methods of railway finance and operation made him one of the most controversial figures in modern railroad history. He pioneered in the establishment of competitive bidding for railway bonds, and his innovations in railway operation included the first "through" transcontinental passenger train service.

Young's apparent overriding ambition was to establish a transcontinental system with the New York Central Railroad as its pivotal line, and he used a spectacular proxy fight in 1954 to wrest

control of the Central from New York investment banking interests. Named board chairman of the Central, he sought to end the road's financial problems and at first the stock rose. But he was unable to overcome the carrier's increasingly difficult plight, and early in 1958 the value of Central stock sank. On January 20 the Board of Directors decided against declaring the quarterly dividend. Five days later, Young took his own life with a shotgun.

YOUNG, Stark, American drama critic and novelist: b. Como, Miss., Oct. 11, 1881; d. Fairfield, Conn., Jan. 6, 1963. After studying at the University of Mississippi and Columbia (M.A., 1902), he spent almost 20 years teaching, resigning as professor of English at Amherst in 1921 to join the editorial staffs of the *New Republic* and *Theatre Arts Monthly*. As drama reviewer and essayist for these magazines during the next two and a half decades and as drama critic for the *New York Times* during the year 1924-1925, he became a vital influence in the New York theater world. He had published early poems (*The Blind Man at the Window*) and *Guinevere*, and the first of several plays, in 1906. His essays on theater art and drama are collected in *The Flower in Drama* (1923), *Glamour* (1925), *Theatre Practice* (1926), *The Theatre* (1927), and *Immortal Shadows* (1948).

During the decade 1926-1935, Young achieved prominence as a writer of historical fiction, and he was associated with the Southern agrarians as a contributor to the symposium *I'll Take My Stand* (1930). His *So Red the Rose* (1934), one of the finest and most popular of Civil War novels, depicts the tragic impact of war on the old plantation way of life in the vicinity of Natchez, Miss. *Heaven Trees* (1926), his first novel, gives an earlier glimpse at the old way of life, treating some of the same characters and their relatives in northern Mississippi during the 1850's. Two other novels, *The Torch on the Flare* (1928) and *River House* (1929), study the effects of these changing conditions on members of Young's own generation. Two volumes of short stories that followed, *The Street of the Islands* (1930) and *Feliciano* (1935), complete the series.

Young made lasting contributions to American letters both as drama critic and as novelist. Other important publications include autobiography (*The Pavilion*, 1951) and translations from Anton P. Chekhov (*Best Plays*, 1956). After retiring in 1947 as drama critic he turned his creative efforts to art and received some attention as a painter.

WILLIAM BRACY
Department of English
Beaver College

YOUNG, Thomas, English physicist and physician: b. Milverton, Somersetshire, England, June 13, 1773; d. London, May 10, 1829. Of Quaker parentage, he read fluently at the age of 2 and by 14 had mastered Latin, Greek, French, Italian, Hebrew, Persian, and Arabic. He studied medicine in London, Edinburgh, Göttingen (M.D., 1796), and Cambridge, and in 1799 established himself as a physician in London. From 1801 to 1803 he was professor of natural philosophy at the Royal Institution, publishing *A Course of Lectures on Natural Philosophy and the*

Mechanical Arts (1807), based on his courses there. In 1802 he became foreign secretary of the Royal Society, of which he had been elected a fellow in 1794, and he held this office for the remainder of his life. In 1811 he was elected physician to St. George's Hospital in London, a post he also held until death, and in 1818 he was appointed secretary to the Board of Longitude, superintending the preparation of the *Nautical Almanac*.

Young strongly supported Christian Huygens' wave theory of light, mainly by virtue of his now famous double-slit experiment (1801) demonstrating the interference of light waves (see *LIGHT—The Wave Theory*). He was the first to describe and measure astigmatism (1801). He also proposed a theory of color vision later developed by Hermann Ludwig Ferdinand von Helmholtz and known as the Young-Helmholtz theory, and made important contributions to the theories of elasticity (Young's modulus of elasticity), hemodynamics, capillarity, and tides.

Young's amazing versatility is further evidenced by the fact that he became a noted Egyptologist, being among the first to decipher Egyptian hieroglyphic inscriptions, including the Rosetta stone (1818), and to work out the hieroglyphic alphabet. Among his many important papers is *An Account of the Recent Discoveries in Hieroglyphical Literature and Egyptian Antiquities* (1823).

YOUNG, Whitney Moore, Jr. (1921-1971), American educator, social work administrator, and civil rights leader. He was born at Lincoln Ridge, Ky., on July 31, 1921, and received degrees from Kentucky State College (B.S., 1941) and the University of Minnesota (M.A., 1947). He taught at the Nebraska School of Social Work, Creighton University, and the Atlanta University School of Social Work, where he was dean from 1954 to 1961.

In 1961, Young became executive director of the National Urban League (q.v.), a biracial organization formed to secure equal opportunities for Blacks. Elements of his "domestic Marshall Plan" were incorporated into the federal antipoverty program during the 1960's. Among his writings is *To Be Equal* (1964). Young died in Lagos, Nigeria, on March 11, 1971.

C. ERIC LINCOLN
Union Theological Seminary

YOUNG IRELAND, a radical Irish political group active between 1840 and 1850. They first followed Daniel O'Connell, who worked for Catholic emancipation. The Young Ireland adherents soon became more extreme in their opinions, advocated physical force, and in 1844 separated from the more conservative Irish nationalists.

Among the party leaders were Charles Gavan Duffy, Thomas O. Davis, and John Blake Dillon, whose political journal, the *Nation*, constantly incited the Irish people to revolt. In 1848 John Mitchel, one of the leaders of the party, was arrested for treason and sent to Tasmania. The attempted insurrection which followed soon collapsed. Two other leaders, Thomas Francis Meagher and William Smith O'Brien, were transported also. Later Mitchel and Meagher and many other Young Irelanders escaped and began to organize Irish resistance overseas. See also *HOME RULE; IRELAND—History*.

YOUNG ITALY (GIOVINE ITALIA), an Italian political society formed in 1831 by Giuseppe Mazzini (q.v.), whose aims were the emancipation of Italy from domestic and foreign (chiefly Austrian) tyrannies, and the unification of the country under a republican government. Its activities declined after 1834, when Mazzini led an unsuccessful invasion of Savoy, but the society was of service in arousing Italian patriotism, and it formed the model for similar organizations elsewhere in Europe. See also ITALY-3. *History* (From the French Revolution to Unification): Restoration and Risorgimento.

YOUNG MEN'S AND YOUNG WOMEN'S HEBREW ASSOCIATION (YM-YWHA) or JEWISH COMMUNITY CENTER, a type of Jewish community organization in the United States, Canada, and other countries, providing social, cultural, physical education, and camping activities for all age groups. Its aim is to perpetuate Judaism as a positive factor in community life through recreation, health education, democratic training, and informal education in Jewish culture. Until the early 1930's, the "Y's" were primarily youth-serving agencies, although in their earlier days they played a significant role in the United States in the adjustment of immigrants to American life. As they broadened their programs to include all elements in the Jewish community, the name Jewish Community Center was more generally adopted, but a few of the oldest and some of the newest units continue to favor the older YM-YWHA designation.

The centers trace their origin to Jewish young men's literary societies established in various American cities in the 1840's. The first organization to be called the Young Men's Hebrew Association (YMHA) was formed in Baltimore, Md., in 1854. The YMHA in New York City was founded in 1874. The name Young Women's Hebrew Association (YWHA) was first applied to a woman's auxiliary of the New York organization in 1888, and the first independent YWHA was founded there in 1902. The YM and YWHA's eventually merged everywhere into single organizations.

In 1913 the National Council of Young Men's Hebrew and Kindred Associations was formed, uniting 175 YM and YWHA's throughout the United States. This, in turn, merged in 1921 with the National Jewish Welfare Board (JWB), founded in 1917 to provide for the religious needs and welfare of Jews in the United States armed forces in World War I. The JWB, with headquarters in New York City, continues to serve as the national association of Jewish community centers and "Y's" in the United States. The local centers are autonomous, but the JWB provides important aid in planning and programming; personnel recruitment, training, and placement; building planning and construction; and administrative services and publications. The parallel organization in Canada is the Canadian Council of YM-YWHA's, whose headquarters are in Toronto. The center movement has now taken root throughout the free world, particularly in western Europe and Israel. The associations in some 19 countries are linked through the World Federation of YMHA's and Jewish Community Centers, founded in 1946, with headquarters in New York City.

By the mid-1960's there were more than 300 Jewish community centers or "Y's" in over 240

cities of the United States and Canada, with a combined membership of nearly 700,000. These centers employed more than 1,500 professional social group workers and maintained, owned, or sponsored some 275 day camps and over 100 resident summer camps. Characteristic activities, covering all age groups, include arts and crafts programs, dramatics, physical and health education, music groups, concerts, hobby groups, lectures, forums, and camping. Nursery schools are maintained and special "golden age" clubs for the elderly. On a national scale, the JWB sponsors an annual Jewish Book Month, Jewish Music Festival, and Jewish Youth Week, in which the centers participate. Its Jewish Community Center World Fellowship project provides opportunities for cultural and athletic contacts between center members in the United States and their counterparts in Israel, Canada, Latin America, and Europe.

BERNARD POSTAL,

Director of Public Information, National Jewish Welfare Board, New York City.

YOUNG MEN'S CHRISTIAN ASSOCIATION (YMCA), an organization defined in the constitution of the National Council of the YMCA's in the United States as a "worldwide fellowship united by a common loyalty to Jesus Christ for the purpose of developing Christian personality and building a Christian society." The Christian orientation of the "Y" is intended to define its purposes and the influence it seeks to exert, not to exclude any who share its ideals or who wish to participate in its activities. Composition of the membership varies from country to country, according to the national pattern, whether Protestant, Roman Catholic, Orthodox Eastern, or other. In the United States the members are predominantly of Protestant affiliation or background, but include substantial numbers of Roman Catholics, members of the Orthodox Christian churches, Jews, and persons of other or no religious affiliation. Since the early 1930's the associations in the United States have accepted women and girls as members along with men and boys.

By the 1960's the more than 1,800 YMCA's in the United States had a membership of about 2,800,000, representing a growth of over 50 percent since 1950. Of this total, almost a quarter were women and girls, and about three fifths were under 25 years of age. Total world membership was about 4,000,000.

Activities and Organization.—YMCA's in American communities are usually organizations of substantial size, with specialized "Y" buildings making possible a wide variety of social, cultural, athletic, and other recreational activities. The practical working objective of these programs is to provide experience that will help members and other participants (1) to understand, accept, and respect themselves as individuals; (2) to develop a faith to live by, based on the life and teaching of Jesus; (3) to form habits of health and physical fitness; (4) to grow as responsible members of their families; (5) to accept the privileges and responsibilities of citizenship in their own groups and in community life; (6) to develop and work for interracial and intergroup understanding; (7) to develop a sense of world-mindedness; and (8) to develop and use responsibly whatever capacities for leadership they possess. To these ends the local associations present programs that include all-around interest clubs for young men and young

Group activities directed toward physical fitness and good citizenship are part of the YMCA program.

YMCA

women and for high school and grade school youth, adult education classes and groups (vocational and cultural), physical fitness classes, swimming and water safety instruction, public affairs forums, religious study groups, choruses, orchestras, youth and family camps, and educational travel opportunities.

Each local YMCA is an autonomous organization, with management in the hands of a lay board of directors, elected by the members, and related committees and councils. Program and group-activity leaders are mostly volunteers. Board, committee, council, group, and club leadership posts in the associations of the United States numbered over 400,000 by the 1960's. There were also about 4,000 full-time professional staff members, including professionally trained secretaries, youth and adult program directors, and directors of physical education, responsible for over-all direction and supervision.

Local associations in the United States are affiliated through the National Council of Young Men's Christian Associations and 17 area councils or state committees, which provide service and leadership to strengthen the local associations in program adaptation and invention, personnel recruitment and training, administration, building design, fund raising, and management. A similar national council exists in Canada. The national councils of the United States and Canada are active participants in the World Alliance of Young Men's Christian Associations, with headquarters at the John R. Mott House in Geneva, Switzerland, which federates YMCA effort in 83 countries. Under its guidance, a World Service gives aid in professional personnel and project support for the development of YMCA's all over the world. Through this agency the North American YMCA's have contributed to the development of Young Men's Christian Associations in 46 of the 83 countries where the "Y" has been established.

History.—The first Young Men's Christian Association was organized in 1844 by George Williams (q.v.), then a 22-year-old dry-goods clerk in London, England. Its stated purpose was to improve the spiritual condition of young men in the drapery and other trades. This aim was quickly expanded to cover the "spiritual and mental" interests of the participants. Religious meetings and personal counsel to young men coming into the city were primary activities, and the first center was a reading room.

Associations on the London pattern were organized in Montreal, Canada, and Boston, Mass., in 1851. In 1854 the associations in the United States and Canada formed an International Com-

mittee for mutual aid and to encourage the organization of new associations; in 1912 a separate national council was organized in Canada, and in 1924 in the United States. Meanwhile, the idea had also taken root on the European continent. In 1855 a world conference of YMCA's was convened in Paris, with representatives from Belgium, the British Isles, Canada, France, Germany, Holland, Switzerland, and the United States, and this conference established what is now known as the World Alliance of Young Men's Christian Associations.

The program characteristic of the American YMCA's got its impetus in 1886, when the association in New York City stated its objective to be the improvement of the spiritual, mental, social, and physical condition of young men. In 1869 the associations in San Francisco, Washington, D.C., and New York City constructed new buildings which included gymnasiums. In 1885 the Brooklyn Central "Y" added a swimming pool. Basketball was invented in 1891 at the YMCA's training school, Springfield College, in Massachusetts, by a staff member, James Naismith (q.v.). Volleyball was invented at Holyoke, Mass., in 1895 by the "Y" physical director, William G. Morgan. Luther Halsey Gulick (q.v.), of Springfield, stressed the concern for "wholeness" of life—spirit, mind, body—in introducing the triangle as the association's symbol.

The YMCA began to undertake service to members of the armed forces in the United States through a Christian Commission during the Civil War. It supplied many services during World War I at the request of the War Department and aided prisoners of war on both sides, working through neutrals. During World War II it was one of the six member agencies of the United Service Organizations (USO).

Associations were organized on the campuses of the state universities of Michigan and Virginia in 1858. In 1895, the leader of the college and university associations in the United States, John Raleigh Mott (q.v.), was a prime mover in bringing together student movements around the world in the World Student Christian Federation. Specialized work with boys began in 1869. A camp for boys was started in 1885 at Orange Lake, N.Y. Later came Hi-Y clubs of senior and junior high school boys (now including girls as well), Gra-Y clubs of grade school boys and girls, and a Y-Indian Guide program for fathers and sons.

A YMCA was established in Calcutta, India, in 1854, but it did not survive. Several associations started in the mid-1870's did; these and others were spurred greatly by aid from a North

American fraternal secretary beginning in 1889. In Japan and China the YMCA was introduced in missionary schools in the late 1880's, and then in the major cities, also with North American assistance. An association was organized in Cairo, Egypt, in 1892 with staff help from England. From similar beginnings the YMCA has grown throughout Asia, Africa, the Middle East, and Latin America. Stress in aid is now on self-led associations, Christian in orientation but related to nation building in the countries themselves.

YMCA's were still active in Communist China in the early 1960's, though with what freedom was not known; they had played no part in the world organization since the revolution. There were no YMCA's in the USSR or European Communist countries. Exchanges for mutual understanding, however, between the YMCA's of the United States and Communist youth organizations were growing in number.

YOUNG PRETENDER. See STUART, CHARLES EDWARD LOUIS PHILIP CASIMIR.

YOUNG WOMEN'S CHRISTIAN ASSOCIATION (YWCA), a worldwide organization designed to promote the welfare of women and girls everywhere, regardless of race, class, creed, or nationality. It was founded in England in 1855 as two separate groups: a Prayer Union, established by Emma Roberts, and the General Female Training Institute, founded by Mary Jane Kinnaird (Lady Kinnaird). The purpose of both groups, which soon united as the YWCA, was to improve the situation of women under conditions brought about by the Industrial Revolution. By 1858 the movement had spread to New York City, and in 1866 a YWCA was opened in Boston. Thereafter the movement expanded rapidly throughout the United States and other countries, becoming one of the largest and most influential world organizations of women. By the 1960's membership in the United States was more than 2,000,000.

Purpose and Organization.—From its earliest beginnings the YWCA has brought women and girls together to work on their common problems and interests, and aspirations for human welfare. All of its activities have been motivated by its deeply rooted Christian purpose, expressing itself in deeds: "To build a fellowship of women and girls devoted to the task of realizing in our common life those ideals of personal and social living to which we are committed by our faith as Christians. . . . In this endeavor we seek to understand Jesus, to share His love for all people, and to grow in the knowledge and love of God." Membership in the YWCA is open to all girls and women without subscribing to this purpose, but those who do subscribe to it have the opportunity to take part in determining the continuing program of the association and to become eligible for positions of leadership. The

isignia of the organization, an inverted triangle, symbolizes the threefold emphasis of the YWCA program—growth of body, mind, and spirit.

In the United States, YWCA's have been united since 1906 in a national association called the Young Women's Christian Association of the United States of America, whose executive body is the National Board, with headquarters in New York City. The board is chosen to carry out policies and principles adopted by the voting delegates at national conventions held every three years. The national association, in turn, is affiliated with the World YWCA, founded in 1894, with headquarters at Geneva, Switzerland, which by the 1960's united YWCA organizations in 72 countries throughout the world. In the United States there were YWCA programs in some 4,600 locations, including over 400 community YWCA's, more than 200 branches and centers, over 100 resident camps, about 300 residences, and nearly 500 student associations.

Activities.—The YWCA provides activities for groups of all ages and interests. The Y-Teen program, for girls and boys, offers recreation, education, citizenship training, service projects, and opportunities to develop social relationships. A program for young adults provides activities for married and unmarried working women, and often for men under 35. Included in the Young Adult group is the Y-Wives program of recreational and educational activities for young mothers of children under school age. The YWCA also serves an increasing number of families with hobby groups, classes, job training, gymnastics, camping, sports, and a wide variety of projects designed for the enjoyment and development of entire households and the consequent strengthening of family life. In all the principal cities of the United States, the YWCA continues to help meet an important need through its residences for young women who are beginning their work experience in new surroundings.

The college and university YWCA program, dating from 1873, offers students opportunities for freedom of inquiry and expression regarding the Christian religion. The campus groups constitute a source of leadership, not only for the YWCA, but for the communities in which these young persons work after graduation.

The YWCA places strong emphasis on its international character. As a part of the mutual service program of the World YWCA, the International Division of the YWCA in the United States offers regular aid to national associations in some 25 or 30 countries by providing advisory secretaries, program and money grants, and international leadership training. The first American advisory secretary went overseas in 1894. Such secretaries help other countries to develop YWCA's of their own, assist in leadership training, and provide general advisory services for founding, strengthening, and expanding the programs of YWCA's abroad.

In times of national emergency, the YWCA has taken a leading role. In World War I it carried on an extensive program for armed services personnel in the United States and overseas. This work, financed in cooperation with a group of other national organizations engaged in similar services, was the forerunner of the United Service Organizations (USO) of World War II. In 1940 a World Emergency Committee was formed for relief work overseas, and the following year the YWCA of the United States was one of the six

founding organizations of the United Service Organization (USO), in which it continues to participate.

Throughout its history, the YWCA has encouraged certain aspects of its program in the United States to develop into independent movements. Organizations which had their beginnings in the YWCA include the National Travelers Aid Association, the American Council for Nationalities Service, and the National Federation of Business and Professional Women's Clubs, as well as day nurseries and women's exchanges. Another prominent outgrowth of YWCA work is the expansion and intensification of the concept of group work, now a major concern of social-work teaching and practice.

LOUISA WILSON HAGER,
Director, Bureau of Communications, National Board of the Young Women's Christian Association of the United States of America, New York City.

YOUNGBERRY, a trailing blackberry, originated by Byron M. Young of Louisiana in 1905 as a hybrid between the Phenomenal and the Mayes dewberry. Also called the Young dewberry, it was introduced commercially about 1926. Because of its high flavor and productiveness it soon became an important variety in Southern and Pacific Coast states. In 1936 the Boysen dewberry (boysenberry) was introduced. It is very similar to the youngberry but has larger and tarter berries, which ripen about ten days later than the youngberry's. The boysenberry has largely replaced the youngberry on the Pacific Coast, but both are grown to some extent from the northern part of Florida to Texas and Oklahoma, and as far north as southern Missouri and southeastern Virginia. The youngberry is not fully hardy farther north, nor is the climate of central Florida cold enough for it to grow well. The berry is one of the finest flavored of the bramble fruits, wine red when ripe, but too soft to allow it to be shipped great distances. It is highly prized as a frozen product and for jam and pies. It ripens over a period of several months, just after the strawberry.

The growth and culture of the youngberry are similar to those of the boysenberry. It is not resistant to leaf spot and anthracnose, and it occasionally sports to a thornless type that is not as productive as the thorny youngberry. Several new varieties similar in growth and berry have been bred and introduced by the Oregon Agricultural Experiment Station and the United States Department of Agriculture. Among them are Cascade (finest flavor), Chehalem (black), Marion (black), Olallie (black), and Aurora (early, firm). However, these varieties are still adapted only to the growing conditions in the Pacific Coast States.

GEORGE M. DARROW
Author of "The Strawberry: History, Breeding and Physiology"

YOUNGER, Cole (1844–1916), American outlaw, who was a member of the James gang. Thomas Coleman Younger was born near Lees Summit, Jackson county, Mo., on Jan. 15, 1844. His service as a Confederate guerrilla officer during the Civil War caused his family to be persecuted by Union sympathizers, and in 1862 his father, though a Unionist, was murdered by a company

of Union guerrillas. After the war, Cole and three of his brothers joined the Jesse James gang, organized in 1866 (see **JAMES, JESSE**). Cole took a prominent part in most of its exploits until wounded and captured with his brothers James and Robert in an unsuccessful holdup of the bank in Northfield, Minn., on Sept. 7, 1876, during which two townspeople were killed. The Youngers, pleading guilty, were sentenced to life imprisonment; Robert died in prison in 1889, but in 1901 Cole and James Younger were paroled, thanks to the former Confederate officer Warren C. Bronaugh, who contended that they had become criminals because of the treatment of their family during the Civil War. Pardoned in 1903, Cole returned to Missouri. He made lecture tours and once appeared in a Wild West show. He died in Lees Summit on March 21, 1916.

YOUNGHUSBAND, Sir Francis (1863–1942), British explorer and political administrator in India, who was instrumental in opening Tibet to British trade. He was born in Murree, India (now in Pakistan), on May 31, 1863. The son of a senior officer of the British Army in India, he was trained at the Royal Military College, Sandhurst, joined the 1st Dragoon Guards in India in 1882, and in 1890 was transferred to the Indian Political Department. Meanwhile, in 1886, he had begun his explorations as a member of a government of India mission to Manchuria. He traveled through central Asia, discovered the Aghil mountains, and proved that the Great Karakoram was the water divide between India and Turkestan before returning to India from Peking via Sinkiang in 1887. The neighboring Pamirs, the "Roof of the World" (now mostly comprised in the Tadzhik Republic of the USSR), were penetrated by him in 1889, when he also made a survey of Hunza, which Russia was eyeing. Younghusband was in the Pamirs again in 1890–1891, and after the British occupation of Hunza in 1892, he was made political officer there. He subsequently served as political agent or resident in various princely states and in 1896–1897 was correspondent of the London *Times* in the Transvaal and Rhodesia.

As Russian influence in Tibet became of increasing concern to the British, Younghusband was sent as envoy to Lhasa in July 1903 with an escort of 200 Sikh pioneers. No entry permit was forthcoming from the Tibetan government, however, and London decided to send the mission in with a brigade under Col. James R. L. Macdonald. After a difficult and long advance and several minor actions, the mission and its escort marched into Lhasa on Aug. 3, 1904. A treaty signed on September 7 marked the successful accomplishment of its objective to open Tibet to British trade (see also **TIBET—History**). Younghusband was rewarded with promotion to lieutenant colonel and a knighthood. He returned to England in 1905 and lectured at Cambridge but subsequently went back to India and was a British resident in Kashmir (1906–1909). After his return to England, he became president of the Royal Geographical Society (1919) and helped to organize several of the earlier attempts to scale Mount Everest. His many books include *Heart of a Continent* (1896); *India and Tibet* (1910); *The Epic of Mount Everest* (1927); *Life in the Stars* (1928); *The Living Universe* (1933); and *The Sum of Things* (1939). He died in Lytchett Minster, Dorset, on July 31, 1942.

YOUNGSTOWN, a city in northeastern Ohio, the seat of Mahoning county, on the Mahoning River, 65 miles (105 km) southeast of Cleveland. Lying about halfway between New York and Chicago and midway between Cleveland and Pittsburgh, and situated near coalfields, Youngstown has an ideal location for manufacturing and distribution. It is a city of heavy industry and one of the leading steel-producing districts of the United States. Besides steel, its industries manufacture aluminum extrusions, asphalt pavers, automotive equipment, office furniture, cement and cement products, corrugated containers, forgings, dies and jigs, rolling-mill machinery, and other products.

Youngstown's economy was shaken in 1977-1978 when Youngstown Sheet and Tube, a big steel company, laid off 5,000 workers and merged with another steel company, forming the third-largest steel company in the nation.

The Ohio Turnpike has three interchanges to the city. Youngstown is also served by six railroads and by trucking facilities and bus lines. The Youngstown municipal airport is the home base of the largest fleet of executive planes in the country.

Recreational facilities include beautiful Mill Creek Park. It covers 2,383 acres (955 hectares) and contains 37 miles (60 km) of drives and foot trails.

Youngstown's musical activities are provided by the Monday Musical Club and the Youngstown Symphony Society. The Youngstown Playhouse conducts a year-round community drama program. The Butler Institute of American Art has paintings, casts, and sculptures. A large collection of historical objects related to the Mahoning region is in the Arms Museum of the Mahoning Valley Historical Society. An extensive public-library system serves the county and includes bookmobile services. Youngstown State University and Penn-Ohio Junior College are in the city.

Youngstown was named after John Young, who came to the area in 1797 and bought an entire township from the Connecticut Land Company. After small pockets of iron ore were discovered, Daniel and James Heaton built the first blast furnace in Ohio in 1803. Afterward, coal and limestone were discovered nearby, both of which are used in smelting iron ore, and Youngstown became a leading producer of iron. In 1895 the first steel was poured, and Youngstown converted from iron to steel production. Over the years, miles of steel plants were built along the Mahoning River.

Youngstown was organized as a township in 1802, incorporated as a town in 1848, and chartered as a city in 1867. The city's government operates under a home-rule charter and has a mayor-council form of government. The mayor and the eight council members are elected to two-year terms. Population: 95,732.

YOUNGSTOWN SHEET & TUBE CO. v. SAWYER, a 1952 ruling of the U.S. Supreme Court nullifying President Harry Truman's seizure of the steel mills. When steelworkers threatened a nationwide strike the president ordered Secretary of Commerce Charles Sawyer to seize the mills, arguing that the U.S. war effort in Korea might be crippled. In June 1952, however, the court nullified the seizure, holding in a 6-3 decision that the president had violated the principle of separation of powers.

YOUNGSTOWN STATE UNIVERSITY, a public institution of higher learning in Youngstown, Ohio. It offers associate, bachelor's, and master's degrees in chemistry, engineering, engineering technology, music, teacher education, and technical nursing. Enrollment is about 10,000.

Youngstown State University was established as the School of Law of the Youngstown Association School, with first instruction offered in 1908. It was chartered as an independent institution in 1920 and was named the Youngstown Institute of Technology the following year. It adopted its present name in 1967.

YOUTH. See ADOLESCENCE.

YOUTH, a short story by the English author Joseph Conrad, written in June 1898. It was published in *Blackwood's Magazine* in September 1898 and, together with *Heart of Darkness* and *The End of the Tether*, in the volume entitled *Youth* (1902).

The narrator Marlow, a character also used in other works, recounts what is actually an autobiographical record of Conrad's first voyage to Asia (1881-1883) aboard the *Palestine*, here named the *Judea*. The old ship, captained by an old man on his first command, has to return to dock three times for repairs. Landsmen jeer at the *Judea* and say she will never get to Bangkok, which to the 20-year-old second mate Marlow is a magic name. It is a story of youth's quest of the unknown, the romantic, the dream that is challenged by grim, unforeseen realities. When the ship leaks, her crew pumps out water, but in the Indian Ocean the cargo of coal catches fire, and they have to pump water into her. So "man is born to trouble, to leaky ships, and to ships that burn." *Youth*, noted for its narrative skill, is an early Conrad work of poetic power.

R. W. STALLMAN, *Editor of "The Art of Joseph Conrad: A Critical Symposium"*

YOUTH EMPLOYMENT AND DEMONSTRATION PROJECTS ACT, a federally funded U.S. program designed to alleviate unemployment among young people. Funded under the federal Comprehensive Employment and Training Act (CETA), the act is implemented under four overall programs.

The Young Adult Conservation Corps, modeled on the Civilian Conservation Corps of the 1930's, provides conservation-related jobs in national forests and other public lands. It complements an earlier program, the Youth Conservation Corps, that provides teenagers with summer conservation jobs. The Youth Community Conservation and Improvement Projects distribute money to states and localities to provide work renovating public buildings, improving inner-city housing, and maintaining parks and other public urban areas. Youth Incentive Entitlement Pilot Projects are designed to offer incentives to disadvantaged youths to remain in high school or to induce dropouts to return to school. The projects guarantee part-time jobs during the school year and full-time jobs during the summer. The Youth Employment and Training Program sets up work-study arrangements with school vocational departments, arranges apprenticeships, and offers academic credits. A portion of the funding of the Youth Employment and Demonstrations Projects Act is set aside for young American Indians and young members of migrant worker families.

YOUTH HOSTEL, hos'tal, a form of low-cost accommodation for travelers, particularly young people on hiking, bicycling, and horseback-riding trips. Persons who use hostels are called hostelers, and traveling between hostels is called hosteling. The idea for hostels first occurred to the German teacher Richard Schirrmann in 1909, and by 1911 he had 17 hostels operating in Germany. Youth hostels were introduced in the United States in 1934 by Isobel and Monroe Smith at Northfield, Mass.

More than 60 nations throughout the world have youth hostels affiliated with the International Youth Hostel Federation. The number of hostels in each country varies from fewer than 10 in Iceland to more than 950 in Poland. Japan has more than 500, many in scenic tourist areas. Large numbers of hostels are located in western Europe and the British Isles, as well as in the eastern European nations of Poland, Czechoslovakia, Hungary, Bulgaria, and Yugoslavia. Hostels can also be found in Latin America, Africa, India, Australia, and the Philippines.

The United States has more than 300 hostels, with the densest concentrations in the Northeast, the Great Lakes area, the Rocky Mountains, and the Northwest. Most of these hostels are privately owned and often operated by the owners as a part-time hobby or as a source of supplementary income. Hostelers pay modest fees. Maximum stay at a hostel is three nights, except by special arrangement. Alcohol and drugs are not permitted, and smoking is allowed only in designated areas.

In the United States and Canada, a hostel may be located in a college dormitory, a converted church, a mountain lodge, or, as in Ottawa, in an old city jail. In other parts of the world hostels can be found in medieval castles, old mills, or former railway stations. In Sweden, a three-masted sailing vessel moored in Stockholm harbor serves as a hostel.

Membership in American Youth Hostels, Inc. (AYH) is open to everyone, and there is no age limit. Membership in AYH has grown steadily from about 11,500 in 1954 to more than 90,000. The AYH pass is valid at any of the more than 5,000 hostels in the world. In addition to individual passes, AYH offers a family pass, which is honored only in the United States and Canada. Families anticipating travel abroad need to buy individual passes for each member of the family. Some hostels have family quarters available, but most often hosting families have to conform to dormitory-style arrangements. Passes are issued for the calendar year and are good through December of the year of issue.

Hostels are often located 10 to 15 miles (16-24 km) apart, in loops or circuits, so that hostellers can hike in a day from one to another. Since the emphasis is on physical exercise, public or motor transportation is ordinarily used only to reach the start of a hostel circuit.

Hostelers are expected to do simple chores, such as cleaning up after themselves, making beds, doing dishes, sweeping floors, and the like. The basic premise of hosteling is to leave a place better than one found it. In the United States hostels are supervised by "houseparents." Outside the United States custodians are generally paid, and the hostels are usually owned by the hostel organizations themselves, with or without subsidies from local or national governments, or private philanthropies.

Many schools in the United States have organized hostel clubs. The AYH sponsors bicycling and camping trips of 4 to 11 weeks in the United States and abroad. Local councils sponsor hiking, cycling, canoeing, and skiing trips for one day to four weeks.

Commenting on his hosteling experience, President Franklin D. Roosevelt, honorary president of the AYH in 1936, said: "I was brought up on this sort of thing and realize the need for hosteling. From the time I was 9 until I was 17, I spent most of my holidays bicycling on the Continent. This was the best education I ever had; far better than schools. The more one circulates in his travels, the better citizen he becomes, not only for his own country, but of the world."

National headquarters of American Youth Hostels, Inc., are in Washington, D.C. 20005. Hostel locations and specific information can be found in the *AYH Handbook*, which comes free with the AYH pass. The *International Handbook*, which may be purchased from AYH, contains information about the 5,000 hostels in the International Youth Hostel Federation.

THOMAS L. NEWMAN
American Youth Hostels, Inc.

YOUTHFUL OFFENDER, the legal status granted in the United States to a young person, generally 16 to 19 years of age, who has committed a crime not punishable by death or life imprisonment and has not previously been convicted of a felony. Such a person, on application to the court, can be given the status of youthful offender. This ensures that all proceedings will be kept secret, the young person's name will be protected, and rehabilitation will be encouraged. The adjudication of the case is not legally considered a conviction.

YPRES, è'prä, a town in Belgium, in West Flanders province, 30 miles (48 km) southwest of Bruges. In the Middle Ages, Ypres (Dutch, Ieper) was one of the most powerful and prosperous cities in Flanders, mainly because of its textile production, which remains its main industry and market. During the 13th and 14th centuries it must have had a population of 80,000, although a document by Pope Innocent IV, dated 1247, mentions 200,000. The city was repeatedly attacked, and a siege by the English in 1383, during the Hundred Years' War, put an end to its prosperity. Testimony to the former greatness of Ypres is the 13th century Halles (market), which is an impressive Gothic building partially destroyed in World War I and reconstructed. The Halles now houses a museum and city government offices.

Of the numerous patrician houses that Ypres once contained, only the Biebuyck House (16th century) remains. The Belle Hospital, now a museum, was built in the 13th century. St. Martin's Cathedral (13th century) and the medieval Butchers' House, now a municipal and war museum, have been reconstructed, as have many of the old houses in the center of the town.

Around Ypres are large cemeteries for Allied soldiers killed in World War I, and in the town itself the Menin Gate commemorates the British dead. During the war the Allies suffered 300,000 casualties in defense of the town, and in the Second Battle of Ypres (1915) the German Army used poison gas as a weapon for the first time. Population: (1980) 34,446.

YPRES, Battles of, ē'pra, three battles fought in or near the Belgian town of Ypres during World War I. In the first two battles (1914, 1915) the Allied forces held Ypres despite heavy attacks by the Germans. In the third (1917), a successful British offensive resulted in the capture of the village of Passchendaele. See also **WORLD WAR I—Concluding Operations of 1914; Operations in 1915; Operations in 1917.**

YPSILANTI, ip-sə-lan'tē, a city in southeastern Michigan, in Washtenaw county. It is situated on the Huron River, 30 miles (48 km) west-southwest of Detroit. A residential and industrial center, Ypsilanti manufactures automobiles and automotive parts, paper, ladders, plastics, and sheet-metal machinery. The plant at Willow Run, which now produces automatic transmissions, was famous during World War II as the production center for B-24 bombers. Willow Run Airport, serving the Detroit metropolitan area, has an aeronautical research center operated by the University of Michigan. The city is the home of Eastern Michigan University, which was founded in 1849 as Michigan State Normal School (later College), and Cleary College, established in 1883.

Ypsilanti was settled in its present location in 1823 and was named for the Greek patriot Gen. Demetrios Ypsilanti. It was incorporated as a village in 1832 and chartered as a city in 1858. The city has a council-manager form of government. Population: 24,846.

YSAÏE, ē-zā-ē', Eugène (1858–1931), Belgian violinist. He was born in Liège on July 16, 1858. After studying the violin with his father, he entered the Liège Conservatory when he was seven. In 1868 he won a first prize in violin and chamber music. After further studies under Henryk Wieniawski and Henri Vieuxtemps, he began an international concert career, playing on the Continent and in Britain. In 1886 he organized the Ysaÿe Quartet, which became world famous. From 1886 to 1898 he also taught at the Brussels Conservatory.

In 1894, Ysaÿe played the Beethoven violin concerto with the New York Philharmonic Orchestra, the first of many American appearances. He also became active as a conductor. He formed the Société des Concerts Ysaÿe in Brussels and served as conductor of the Cincinnati (Ohio) Symphony Orchestra from 1918 to 1922. He died in Brussels on May 12, 1931.

Ysaÿe wrote numerous compositions, but they were not performed much. Among them is the opera *Piër li houïeu* (*Peter the Collier*), with a libretto in the Walloon dialect. Written after Ysaÿe's 70th year, it was first performed in Liège in 1931. In 1937, Queen Elizabeth of the Belgians instituted an international violin competition, with the prize named in Ysaÿe's honor. The first winner was David Oistrakh.

YSER RIVER, ē-zār', a river in northern France and western Belgium, about 48 miles (77 km) long. It rises northeast of St.-Omer, France, and flows into the North Sea 2 miles (3 km) below Newport (Nieuport), Belgium. In October 1914 the Allies halted the German offensive against the Channel ports by opening the dikes of the Yser and flooding the countryside.

YTTERBIUM, i-tûr'bē-əm (symbol Yb), a scarce, soft, silver-colored metallic element with atomic number 70 and valence +2 or +3. Ytterbium is the next-to-last member of the rare-earth, or lanthanide, group. It was first identified as a distinct element in 1907 by Georges Urbain in France, and, independently and nearly simultaneously, by Carl Auer von Welsbach in Austria. The element is made up of 7 stable isotopes with mass numbers 168 and 170 through 175, and has an atomic weight of 173.04, a density of 6.997 grams per cubic centimeter, and a melting point of 824°C (1515°F). It is found in several minerals, including monazite, gadolinite, and xenotime, and forms a number of divalent and trivalent compounds, including the white oxide Yb₂O₃ (ytterbia). Ytterbium is obtained by extraction from monazite and other minerals. See also **RARE EARTH.**

YTTRIUM, it'rē-əm (symbol Y), a grayish black trivalent metallic element with atomic number 39. Yttrium in nature is always found together with one or more of the rare-earth, or lanthanide, elements (those with atomic numbers 58 through 71), and aqueous solutions of its salts exhibit chemical properties closely similar to those exhibited by aqueous solutions of rare-earth salts; for these reasons yttrium often has been classified as a rare earth. Yttrium oxide (Y₂O₃, yttria) was discovered in 1794 by the Finnish chemist Johan Gadolin as a constituent of the mineral gadolinite, formerly called ytterbite because it was first found at Ytterby, Sweden. (The elements yttrium, erbium, terbium, and ytterbium are all named after this Swedish village.) Elemental yttrium was first obtained in a relatively pure form by the Swedish chemist Carl Gustav Mosander in 1843.

Yttrium has an atomic weight of 88.92, the stable isotope Y⁸⁹ making up 100% of the naturally occurring element. It has a density of 4.478 grams per cubic centimeter and a melting point of 1509°C (2748°F). The element has a crustal abundance of 28 parts per million, which ranks it somewhat below copper, nickel, and zinc, and slightly above lead and lithium. Yttrium-containing minerals include monazite, gadolinite, euxenite, xenotime, and samarskite. Yttrium is extracted commercially from monazite.

Yttrium is used mainly for making europium-activated phosphors for the color video screens used in television sets and computer monitors. In this application the phosphors give off a brilliant clean red light when excited by electrons. Yttrium-iron garnets (Y₃Fe₅O₁₂) are used in some communications equipment because of their ability to transmit high-frequency energy with low losses. Yttrium is used in the metal industries as an alloying element and as a getter for removing impurities from other metals. Yttrium alloys are potentially valuable as nuclear-reactor moderators.

YÜAN DYNASTY, yü-an', the line of Mongol rulers in China. The nomadic Mongols had already conquered most of the non-Chinese world known to them and had dominated part of China for more than 40 years when in 1271 the fourth khan of khans, Kublai or Khubilai (reigned 1260–1294), proclaimed a Chinese-style Yüan dynasty at Khanbalik (Peking). In 1279 his forces finally exterminated the native Sung dynasty in the south and made him the first foreign conqueror

to rule all China. Kublai's armies also attacked Japan (1274, 1281), Vietnam (1281-1287), Burma (1287), and Java (1292) without incorporating these areas into the Yüan domain.

The Mongols perpetuated China's traditional "Confucian" form of government, but they exploited, humiliated, and discriminated against the Chinese, who consequently have considered the Yüan era a dark age in their history. Yet it was a notable age in many ways. Cotton and sorghum were introduced into Chinese agriculture. Great advances took place in sea transport and naval warfare. There were also important Chinese writers and painters, and novels and dramatic operas emerged as new forms of popular literature. The Pax Mongolica (Mongol Peace) that spread from the Yellow Sea to the Mediterranean permitted Sino-Western exchanges of persons and influences as never before. The Venetian Marco Polo lived in China from 1275 to 1292 and subsequently wrote descriptions of its great cities, vast wealth, and other marvels that astonished generations of European readers. Among other notable European visitors in Yüan China was John of Montecorvino (Giovanni da Montecorvino), who reached Khanbalik in 1294 and served as Roman Catholic archbishop there from 1307 until his death in 1328.

Kublai Khan's 13 Mongol successors on the Chinese throne were not strong rulers, and from the 1320's onward Mongol groups feuded interminably with one another. Their neglect of governmental responsibilities, a long sequence of natural calamities, and the accumulated effects of inflationary issuances of paper money facilitated the rise of Chinese rebels in the 1350's and 1360's. One of these, Chu Yüan-chang, established the Ming dynasty in 1368.

Author of "China: A Critical Bibliography"

YÜAN SHIH-K'AI, yü-an' shir' kī' (1859-1916), Chinese military leader, who became the first president of the Republic of China. He was born in Siangcheng, Honan province, and rose to prominence as the protégé of Li Hung-chang, who virtually dominated North China during the last decades of the 19th century. From about 1885, Yüan served as Li's agent in Korea, where his efforts to check the spread of Japanese influence provoked the Sino-Japanese War of 1894-1895. Although China suffered defeat, Yüan was protected by Li, who gave him the job of training troops in North China. Yüan armed his troops with modern weapons and introduced Western training techniques, with the result that his Peiyang or North Sea Army rapidly became the most powerful military force in China. Consequently, in 1898, when Chinese reformers led by Emperor Kuang Hsü plotted to seize control of the imperial government, they requested Yüan's assistance. Yüan probably exposed their plot to supporters of the Empress Dowager Tz'u Hsi, who routed the reformers and imprisoned the young emperor until his death in 1908.

When the xenophobic Boxer movement engulfed much of North China in 1900, Yüan won considerable support among foreigners by suppressing the insurgents in Shantung, where he had been appointed governor. Thereafter his power grew so quickly that in 1908 the dynasty dismissed him from his command, supposedly in order to avenge the dead Kuang Hsü, but in reality because the Manchus feared Yüan and

wished to reassert imperial control over his troops. Yüan, however, retained the loyalty of his army, which refused to defend the dynasty against the revolution of 1911 until he was reinstated. He persuaded the frightened Manchus to abdicate (Feb. 12, 1912), at the same time using his superior military power to overawe the revolutionaries, led by Sun Yat-sen. The result was a compromise, in the form of a republic with Yüan Shih-k'ai as its president (inaugurated March 10, 1912) agreeing to share power with a popularly elected legislature dominated by the followers of Sun Yat-sen.

In 1913, Sun's revolutionaries tried to overthrow Yüan's increasingly dictatorial regime but were defeated: in addition to possessing the most powerful army in China, Yüan enjoyed the support of foreign bankers, who in return were given a virtual stranglehold on much of China's economy. After destroying the republic, Yüan attempted to make himself emperor. He was frustrated by centrifugal forces generated in large part by his own policy of allowing his commanders to set themselves up as provincial warlords. Most were in rebellion against him at the time of his death in Peking on June 6, 1916.

DONALD G. GILLIN, *Vassar College*

YUBA CITY, yōō'ba, a city in north central California, the seat of Sutter county, on the Feather River, about 40 miles (64 km) north of Sacramento. Its name is derived from that of a Maidu Indian tribe that inhabited the area. A trade, shipping, and processing center for the surrounding agricultural region, which is noted for its peaches, prunes, and nuts, Yuba City has processing plants for feeds and nuts, fruit canneries, and packing plants for frozen fruits and vegetables. Beale Air Force Base is located 10 miles (16 km) to the east.

Yuba City was laid out in 1849 and incorporated in 1908. It has a council-manager form of government. Population: 27,437.

YUCATÁN, yōō-kā-tān', a state in Mexico, at the northern end of the Yucatan Peninsula, with a coastline on the Gulf of Mexico. The state has an area of 16,749 square miles (43,379 sq km) and a population (1980) of 1,063,733.

Except for a range of hills along the southwestern border, Yucatán consists of a sparsely inhabited plain formed of a chalky crustacean deposit. The meager topsoil is often covered by low trees and dense thickets. Rainfall, which is limited and occurs from May to September, seeps through the surface and is collected in underground rivers and in pools, from which it is raised by windmills for irrigation.

Outside of the Mérida-Progreso urban zone, most of the people are rural Maya. Some 40% of the state's population lives in Mérida, the capital, which was linked with Mexico City by rail only in 1950 and by highway only in 1961. Mérida is an important air junction. Progreso, the state's chief port, is 22 miles (35 km) north of the capital.

The chief source of wealth is henequen, from which sisal hemp is obtained. The most important industry is the manufacture of cordage, bags, shoes, hats, and other elaborations of sisal, a native product named for the small port of Sisal, west of Progreso. Sugar and maize are grown in Yucatán, and fishing is conducted off the coast. Good-quality honey, royal jelly, tropical fruits,

and beer also are produced. Tourism is a major source of income, and excellent hotels have been built at the site of the ancient Maya ruins of Chichén Itzá and Uxmal. Other archaeological sites include Mayapán, Yaxuná, Dzibilchaltún, Kabah, Sayil, and Labná.

Author of "Conquest of Mexico"

YUCATAN PENINSULA, yōō-kə-tan', a projection of the North American continent between the Gulf of Campeche on the west, the Gulf of Mexico on the north, and the Caribbean Sea on the east. Its area of about 70,000 square miles (180,000 sq km) comprises the Mexican states of Campeche, Yucatán, and Quintana Roo, part of Petén department in northern Guatemala, and all of Belize.

The extreme southerly portion of the peninsula rises to about 500 feet (150 meters) and is covered by tropical rain forest containing such commercially important trees as mahogany, ebony, red cedar, logwood, and the chicle-producing chicozapote (sapodilla). A chain of low hills, nowhere more than 300 feet (90 meters) in elevation, crosses from the city of Campeche to Che-tumal Bay. The northern part of the peninsula is a dry, stony plain formed by crustacean deposits and subject to rising and sinking. This plain, drained mostly by underground rivers and caverns, supports mesquite, cactus, and the cultivated henequen (sisal), which is the major crop.

The population of the Yucatan Peninsula consists mainly of Maya, descendants of the peoples whose civilization flourished throughout this area long before the Spanish conquest. The civilization of the Classic Period was centered in the southern part of the peninsula between 300 and 800 A.D. Afterward, for reasons not entirely understood, the principal centers of habitation were moved northward to the cities of Chichén Itzá, Mayapán, and Uxmal, which are now important archaeological sites.

The first Europeans to land in Yucatan appear to have been two Spaniards shipwrecked in 1512, although some earlier maps that seem to show a distorted Yucatan coastline would put the peninsula's discovery before 1503. Francisco Fernández de Córdoba explored the coast in 1517 and was followed by Juan de Grijalva the next year. The period of conquest extended from 1519, when Hernán Cortés anchored off Cozumel Island, to 1540, when the Maya were finally subdued by the two Francisco Montejos, father and son. By 1542 the Spaniards had founded Mérida on the site of the Mayan city of T'ho. However, the Maya were not finally subdued until the beginning of the 20th century, by the Mexican government.

YUCCA, yuk'a, a genus of trees and shrubs belonging to the agave family (Agavaceae) and characterized by stiff, evergreen, sword-shaped leaves crowded on a stout trunk. The white or greenish flowers are borne in a dense terminal panicle that faintly resembles a candle. This counts for the common name Our Lord's candle—frequently applied to *Yucca whipplei* of the southwestern desert areas of the United States. Forty species of yucca exist, mostly confined to the arid portions of North America. Spanish

Yucca baccata, commonly called Spanish bayonet, with the dense terminal flowerhead characteristic of yuccas.

bayonet, *Y. baccata*, and other species were a source of fiber for the construction of ropes, sandals, and cloth by the Indians. The roots containing saponin were a source of soap, while the green pods were cooked and eaten by both Indians and early Californians. The Joshua tree, *Y. brevifolia*, attains an average height of 20 to 30 feet (6–9 meters) and is common at the base of desert mountains, with 8 to 10 inches (20–25 cm) of rain, in southern California and adjacent states. A dense forest of these trees in the Mojave Desert was set aside as the Joshua Tree National Monument in 1936.

Yuccas are entirely dependent on various species of nocturnal moths (*Tegeticula*) for pollination of the flowers. Each variety of yucca moth is adapted to a single species of yucca. See also YUCCA MOTH.

HUGH N. MOZINGO, *University of Nevada*

YUCCA MOTH, yuk'a, a moth of the genus *Tegeticula* belonging to the family Incurvariidae. Four species are known. The female gathers a ball of pollen from the stamens of one yucca flower with the help of specialized mouthparts. She then carries this ball to a second plant, and after depositing one or more eggs in the ovary with her long ovipositor, she climbs to the top of the pistil and packs the pollen ball into the depression formed by the stigma. The seeds will then mature, and some of them will serve as food for the moth larva.

The yucca plant seems to be absolutely dependent on the moth for this pollination. The larva, when fully grown, eats its way out of the seedpod and hibernates in or on the ground in a tough cocoon. In the spring the larva pupates, emerging as an adult during the blooming season of the yucca. See also YUCCA.

YUGOSLAVIA, yŏŏ-gŏ-slă'vĕ-ə, a country in south-eastern Europe, in the western half of the Balkan Peninsula. Excluding the Soviet Union, it is second in eastern Europe only to Poland in area and population. Created in 1918 as a centralized, unitary state, Yugoslavia in 1945 became a federation of six republics: Bosnia-Herzegovina, Croatia, Macedonia, Montenegro, Serbia, and Slovenia. The six "nations" (peoples) that these republics were created to represent speak three languages and profess three major religions. Yugoslavia also contains various "nationalities" (minorities), and it is bordered by seven foreign countries. These unusual circumstances of its national life created problems for Yugoslavia that were faced by few other sovereign states.

The complexity and diversity of Yugoslavia's situation can best be understood in the light of history. Ancient Greece had little contact with most of this mountainous area, although some Greek colonies were established along the coast and on the islands of southern Illyria, as the

region came to be called in the ancient world. Several centuries later Rome established a protectorate over the region following its two Illyrian wars, which were fought late in the 3d century B.C. in order to end the Illyrian threat to Roman shipping. In the next two centuries the hinterland of Illyria was brought under Roman control. During the imperial period Illyria served as a source of military manpower, and, in the late 3d century A.D., even of emperors. The emperors Claudius Gothicus, Aurelian, Probus, and Diocletian (whose palace at Split survives), were all of Illyrian origin.

The Roman Empire was divided into two halves, Western and Eastern, after the death of Theodosius the Great in 395 A.D. The lands to the east of a line that followed the Drina River, then cut across what is today eastern Bosnia and through the middle of present Montenegro, became part of the Eastern empire, the lands to

INFORMATION HIGHLIGHTS

Total Area (land and inland water): 98,766 square miles (255,804 sq km).
Boundaries: North, Austria and Hungary; east, Romania and Bulgaria; south, Greece and Albania; west, Adriatic Sea and Italy.
Elevations: Highest—Triglav (9,394 feet, or 2,863 meters); lowest—sea level.
Population: (1981 census) 22,424,687; (1990) 23,842,000.
Capital and Largest City: Belgrade (Beograd).
Major Languages: Serbo-Croatian, Slovene, and Macedonian (all official).
Major Religious Groups: Eastern Orthodox Christians, Roman Catholics, and Muslims.
 For Yugoslavia's flag, see under FLAG, both illustration and text.

the west of the line became part of the Western empire.

From the 3d century on, the Balkan Peninsula was raided repeatedly by barbarian tribes. Slavic invaders first appeared in the peninsula in the 6th century and in the next two centuries succeeded in establishing themselves there. These Slavs, known as South Slavs, were soon divided by geography and historical events. The Croats and Slovenes settled in the north of what became Yugoslavia, and the Serbs in the south. In time the Croats and Slovenes were oriented toward the West and were won to the Western form of Christianity. The Serbs fell under the influence of Byzantine culture and became part of Eastern, or Orthodox, Christianity.

The Serbs, Croats, and Bosnians (the area of Bosnia was settled by South Slavs beginning in the 7th century) all established kingdoms in the medieval period. But with the weakening of these states, the Ottoman Turks were able to win control over most of the region following their victory over the Balkan allied forces on the plain, or *polje*, of Kosovo in 1389. The Ottoman Empire left a lasting mark on the cultures and lives of the peoples under its domination. A large percentage of the Slavic population of Bosnia even converted to Islam.

Ultimately only a few areas in the region escaped Ottoman hegemony. One of these was Slovenia, which in the Middle Ages had become part of the German kingdom and then had passed to the Habsburgs in the late 13th century. Within the Habsburg empire the Slovenes formed 90% of the population of the Austrian province of Carniola and a significant proportion of Styria, Carinthia, and Görz (Gorizia) and Gradisca. Most of Croatia, united with Hungary through the person of a common monarch since 1102, fell to the Ottomans after the Turks had defeated the Hungarians at the Battle of Mohács in 1526. But northern Croatia, including Zagreb, passed in the next year under Habsburg rule.

At the end of the 17th century, the European powers began successfully to challenge the Ottoman control of Christian populations. The Habsburg monarchy, playing the leading role in the western Balkans, occupied most of the rest of Croatia and Slavonia up to the Sava River. The territory was formally ceded to the Habsburg empire by the Treaty of Karlowitz in 1699. Although the same treaty gave Dalmatia to Venice, Dalmatia ultimately passed to the Austrian Empire in 1815.

Serbian revolutionary action began with the outbreak of a revolt in 1804. Serbia first achieved autonomy; then, by a treaty that was concluded at the Congress of Berlin in 1878, it gained its independence. The Congress also negotiated the independence of the principality of Montenegro and granted Austria-Hungary the right to occupy and administer Bosnia and Herzegovina. The Dual Monarchy annexed those provinces in 1908. The part of Macedonia that eventually made up the Yugoslav republic of Macedonia was the last area of Yugoslavia to be separated from the Ottoman Empire. That event occurred in 1913, when Serbia received most of northern Macedonia by the Treaty of Bucharest, which ended the Second Balkan War.

In 1918 these various areas that once had formed part of the Ottoman and Austro-Hungarian empires were merged into the new Yugoslav ("South Slav") state. Yugoslavia also gained the

lands constituting Vojvodina from Hungary. But the present Yugoslav-Italian boundary was not achieved until after World War II.

The complex history of the Yugoslav region is reflected in the basic ethnic and cultural composition of the six republics. The Slovenes and Croats are Roman Catholics, and their system of writing is the Latin alphabet. On the other hand, the Serbs, Montenegrins, and Macedonians are Orthodox Christians, and their writing system is the Cyrillic alphabet. The population of Bosnia-Herzegovina is composed of Bosnian Muslims, who are recognized as a separate people, as well as of Serbs and Croats. Two autonomous provinces were created within Serbia: Kosovo in the south, because of its Albanian majority; and Vojvodina in the north, because of its mixed population reflecting the area's long association with the multinational monarchy of the Habsburgs.

From its birth in 1918, Yugoslavia has had to confront the problems posed by its own multinational composition. Its first government, a centralized regime under firm Serbian control, was not able to win the support of the other peoples; nor could it make significant headway in improving the economy of this impoverished land. The country's post-World War II Communist government sought to solve the multinational problem by decentralizing authority and making a major effort to reconcile the six major peoples and the minorities. At the same time, it tried to improve the economy by expanding and modernizing the industrial sector. The economic system that Yugoslavia's Communist leaders introduced differed from both that of the West and that of the Eastern-bloc countries. In foreign policy as well, Communist Yugoslavia avoided joining either of the Great Power blocs, led by the United States and the Soviet Union. Instead, it made efforts to build and maintain a nonaligned, neutral camp, composed chiefly of Asian and African countries.

Seeking to solve difficult problems in new ways, the Communist Yugoslav government allowed a great deal of experimentation and freedom of action. That characteristic distanced it from other Communist states.

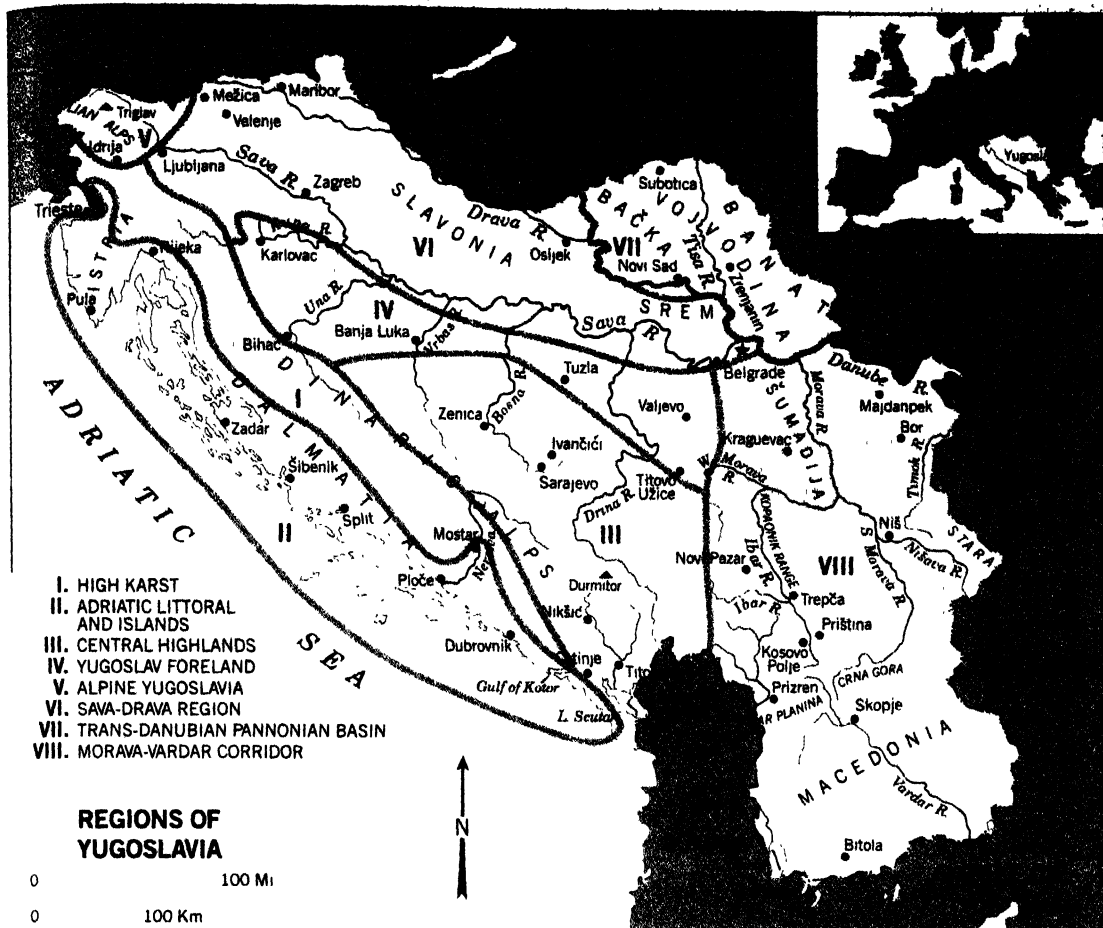

GEOGRAPHY AND PEOPLE

1. The Land and Natural Resources

For a country of its size, Yugoslavia has a surprisingly varied terrain. In general terms the land can be divided into mountainous and high hilly regions, composing three quarters of the total area, and low hill country and plains.

The rugged mountainous areas have impeded communications among the peoples of Yugoslavia. They have perpetuated divisions among them and contributed to the spirit of isolation, separatism, and parochialism. In modern times they have acted as a barrier to the development of roads and railroads for the movement of goods, and have hindered the integration of the more inaccessible areas into the country's economy. It is true that the least accessible parts have served as places of refuge in times of trouble and have resisted conquest. But the lack of fertile soil and the alternation of droughts and floods in many of these harsh regions have not favored agricultural development.

Geological fault lines in the more mountain-

ous regions of the country and in the neighborhood of the Adriatic coast have caused severe earthquakes from time to time. In recent decades Skopje was virtually destroyed, in 1963, and had to be rebuilt. Banja Luka, in northern Bosnia, was devastated by an earthquake in 1969, and earthquakes along the southern Adriatic coast in 1979 did great damage.

The Regions of Yugoslavia. Dominating the physical map of Yugoslavia is the long stretch of the Dinaric Alps between the Julian Alps in Slovenia in the northwest and Albania in the south. This rugged limestone backbone consisting of both broad and narrow ridges and plateaus that are separated by basins and long valleys is the geographic "heartland" of Yugoslavia. Following the Adriatic coast, the Dinarics also fan out to a width of well over 100 miles (160 km) as they reach southward. They occupy about one quarter of Yugoslavia and average 4,000 to 6,000 feet (1,200–1,800 meters) in elevation.

The mountain chain, the axis of which parallels the coast, runs so close to the sea that it restricts the Adriatic littoral to no more than a narrow ribbon of land for most of its length and, lacking transverse valleys across the ranges, blocks the country's coast from the interior.

The High Karst plateau occupies the western section of the Dinarics. To the east and south-east of the High Karst are the Yugoslav Central Highlands. From the Highlands the land descends through the transitional zone of the Yugoslav Foreland to reach the Sava and Morava river basins.

The eastward-flowing Sava and Drava rivers rise in Alpine Yugoslavia in the northwest corner of the country and ultimately join the Danube River. To the north of the Danube River is the fertile Pannonian Basin, which Yugoslavia shares with Hungary and Romania.

Joining the Danube from the south is the Morava River, which with the southward-flowing Vardar River drains a large region embracing most of Serbia and Macedonia. Highlands on Yugoslavia's eastern borders are related to the major mountain systems of Romania and Bulgaria.

The River Network. Like the mountainous regions, the rivers have not served to unify the country because the three major river systems lead in opposite directions. The largest system, the Danubian, ultimately empties into the Black Sea. Most of Yugoslavia's rivers, draining about three quarters of the country, flow into this system. The Danube's major right-bank tributaries in Yugoslavia are the Drava, Sava, and Morava; its major left-bank tributary is the Tisa. The Sava and the Danube into which it flows have historically formed part of a major corridor between the Adriatic and the Black Sea, with access from the Adriatic to the headwaters of the Sava reached through Peartree Pass (Postojna) between Trieste and Ljubljana.

Yugoslavia's only major river emptying into the Adriatic is the Neretva, which cuts through the Dinaric Alps. And the region's outlet to the Aegean Sea is through the Vardar River, which rises in Macedonia and flows southeast through

southern Yugoslavia and Greece to discharge into the Aegean near Salonika. The corridor formed by the Vardar-Morava rivers has provided throughout the centuries the region's major route from the Aegean to the Pannonian Basin via the Danube.

In the lowlands associated with Yugoslavia's major river systems are found the densest population concentrations, the best agricultural lands, the most extensive transportation networks, and the greatest concentration of industry.

Climate. Yugoslavia's Adriatic coast and islands and southern Macedonia near the Aegean Sea have Mediterranean climates, with mild winters and hot summers. The January average is 45°F (7°C); the summer average is 75°F (24°C). At the other extreme the mountain areas have cold winters and short summers with cool temperatures. The other regions have a continental climate with cold winters and hot summers, averaging 30°F (-1°C) in winter and 75°F to 80°F (24°C-27°C) in summer.

Rainfall averages vary widely. The agricultural plains of the northeast receive an average of 25 to 40 inches (635-1,015 mm) and the coast from 25 to 30 inches (635-760 mm). Rainfall is particularly important for the Danubian plain, for a drought there can reduce crop yields dramatically. Macedonia has inadequate rain, and the Vardar Basin is the driest area in the country.

Yugoslavia's climate is also affected by its winds. The *bura* (bora) is a cold wind of great force that in winter descends on the Adriatic coast from the mountainous interior. The *sirocco*, crossing the Mediterranean from Africa, brings warm, moist air to the southern part of the coast, also in the winter. The *vardarac*, a cold wind blowing from the north, modifies Macedonia's winter temperature.

THE REGIONS

The High Karst. Its name derived from Slavic *kras*, and originally applied to a bleak, stony region in the hinterland of Trieste, the Karst of the Dinaric Alps is a region of rugged highlands and plateaus of parallel clefts and ridges. The High Karst, which forms the western part of the Dinaric range, extends for about 350 miles (565 km) from Slovenia in the north through western Croatia, western Bosnia, and Hercegovina. Its greatest width is no more than 50 miles (80 km). On its western flank it drops sharply to the plains along the Adriatic coast. It is breached by only one long river, the Neretva, which reaches the Adriatic through deep gorges. The river's rapid descent has been utilized for the production of hydroelectric power.

Composed of porous limestone, the karstic landscape is honeycombed with sinkholes and caves created by rain eroding the limestone, which is highly soluble in water. Subterranean rivers, fed by water seeping through the crevices in the limestone, run through underground channels in the dissolving limestone. Hollows are formed as the caves collapse with further dissolution of the calcareous rock. The smaller, rounder hollows are called *doline* and the larger, elongated ones *uvale* and *polja* (fields; singular, *polje*). The *polja*, typically surrounded by higher ground, can reach 50 miles (80 km) in length, though they are only a few miles wide.

Until the trees on the High Karst were felled centuries ago for shipbuilding among other purposes, these western flanks of the Dinarics were

well forested. Today the High Karst is an area of glaring white limestone. What soil exists consists of alluvial deposits washed down into the narrow valleys from the highlands when their forest cover was removed, and of thin layers of residual *terra rossa* (red earth) on the floors of the karstic depressions. The latter consists of the less soluble part of the limestone and is fairly fertile.

Subsistence farming is possible in those *polja* where the soil is sufficient and the conditions are generally favorable. But farming them is difficult because they tend to flood when snows melt on neighboring peaks or when rains are heavy, and when the water evaporates in the summer heat, the depressions often turn into dusty, cracked fields.

The Adriatic Littoral and Offshore Islands. Yugoslavia's heavily indented coastline, or littoral, is in most places confined by the Dinaric Alps to no more than a narrow zone of land. Paralleling the Dalmatian coast are many long, narrow islands, the summits of karstic limestone mountains that were submerged as waters rose in the postglacial "drowning" of the coast.

Since most of the rivers flowing down from the High Karst are subterranean, or surface for only brief stretches, the amount of silt that has accumulated on the coastal plains is limited. The one exception is the area around the Neretva, where the river's silt has created a substantial delta. The lack of arable soil and the climatic pattern restrict agricultural development. However, south of Split, wheat, grapes, figs, olives, citrus fruits, and almonds are grown. In northern Dalmatia the major crops are corn, tobacco, and market-garden produce.

Bauxite is mined at various places along the coast. Calcium rock, from which cement is made, is mined near Split and in Istria. The latter is also the source of quartzite sands, zinc, lead, and some coal.

There is some commercial fishing, but shipping activities are of more economic significance, even though access to the interior is hampered by the difficult terrain of the High Karst and its lack of transverse valleys. The best port is Rijeka (formerly Fiume), which is linked to Ljubljana and Zagreb by rail. Of lesser importance are Split, Šibenik at the mouth of the Krka River, Ploče on the Neretva's delta, and Dubrovnik's port of Gruž. The two naval bases on the Adriatic are at Istria's port of Pula and at the port of Tivat on the spacious Gulf of Kotor.

Shipbuilding, food processing, the working of minerals mined nearby, such as the processing of aluminum from bauxite, and the manufacture of products from both local and imported raw materials are the chief industries.

The government promotes tourism along the Dalmatian coast, building both improved highways and modern hotels. The area is famous for its spectacular scenery, for resorts like Opatija near Rijeka, and for its cities of historical interest: Dubrovnik (Ragusa), once a great trading republic; Split (Spalato), with Diocletian's palace; Zadar (Zara), Šibenik, Trogir, and Kotor, which, along with Split, reflect Venetian cultural influences.

Central Highlands. Extending over much of Bosnia, a small part of western Serbia, and Montenegro, these highlands are east and southeast of the High Karst. An area of irregular rugged plateaus, they reach their greatest heights in

Dalmatia's popular beaches, backed against the Dinarics, alternate with rocky headlands along the Adriatic coast.

Montenegro, whose massif Durmitor rises to 8,275 feet (2,522 meters); Mt. Lovćen, between Montenegro's former capital, Cetinje, and the Adriatic, reaches 5,738 feet (1,749 meters).

Although limestone karst dominates the Montenegro uplands, in the rest of the Central Highlands, it gives way to schists, serpentines, shales, and sandstones. Because these rocks, unlike limestone, are impermeable, river systems have developed above ground. Three major rivers, the Vrbas, the Bosna, and the Drina, rise in the Central Highlands, cutting their way across the grain of the highland folds on their descent to the Sava River. Their own tributaries, however, generally flow in valleys paralleling the axis of the folds. The Bosna and Neretva rivers form a natural corridor between the Sava River and the Adriatic Sea coast inasmuch as the headwaters of one can be reached from the other by the Ivan Pass, a route used by ancient Romans, the Ottomans, and by railway builders in modern times.

The only rivers in the highlands not forming part of the Sava drainage system are Montenegro's Morača and its tributary the Zeta, which rises near Nikšić. The two rivers join at Titograd, Montenegro's modern capital, and ultimately flow into Lake Scutari.

Unlike the High Karst, most of the highlands are thickly forested, giving rise—where the forests are accessible—to a substantial lumber industry. Stockbreeding has been traditional in the region's high pastures, at least where the impermeable rock assures an adequate surface water supply. Farming is conducted chiefly in the region's basins.

The Central Highlands are fairly rich in mineral resources, and over the years the government has located industries there near local resources in an attempt to upgrade the economy of this underdeveloped section of Yugoslavia. For

example, in the Sarajevo basin the iron-and-steel complexes at Zenica and Ivančici are based on iron ore mined in the area. Similarly, in Montenegro, steelworks have been developed in Nikšić, based on local iron ore.

The Yugoslav Foreland. An area of gently rolling land lying between the Central Highlands and the Sava River basin, the Yugoslav Foreland reaches from the Kupa River on the northwest to the Šumadija region south of Belgrade. This piedmont occupies a small part of Croatia, northern Bosnia, and the western part of central Serbia. The major tributaries of the Sava that rise in the High Karst and the Central Highlands—the Una, Vrbas, Bosna, and Drina—emerge from their deeply incised gorges to flow across the foreland before reaching the Sava.

Karlovac, the industrial center, is the chief Croatian city in the region. Banja Luka on the Vrbas and Tuzla near the Majevica massif are the region's two major Bosnian cities. A chemical industry has developed around the extensive salt deposits in the Tuzla Basin, aluminum is processed in nearby Zvornik from local bauxite deposits, and iron is mined in the vicinity of Ljubija in northwestern Bosnia. Valjevo, in a fruit-growing area, and Titovo Užice, the center of a stockraising and mining region, are the foreland's chief Serbian cities.

Alpine Yugoslavia. Two ranges of the Alps extend into Slovenia in the northwest corner of Yugoslavia: the Karawanken range, which straddles the Austrian frontier, and the rugged Julian Alps, which are shared by Italy and Yugoslavia. The ranges are separated by the northern arm of the Sava River, the Sava Dolinka. The Karawanken range reaches about 6,000 feet (1,800 meters), declining on the east toward the Drava Valley in the vicinity of Maribor. The highest peak in Yugoslavia is the three-headed limestone mountain Triglav (9,394 feet, or 2,863 meters) in

© J. HEWERDINE/BRUCE COLEMAN INC.

The walled city of Dubrovnik (Ragusa) draws thousands of tourists each year in search of the city's proud past.

the Julian Alps. Southeast of Triglav is Lake Bohinj, the source of the other arm of the Sava, the Sava Bohinjka. The two branches of the river join at the resort lake of Bled near the Austrian border.

The thickly wooded hills and cultivated valleys of the region have the look of neighboring Austria. One of the country's oldest mercury mines is located at Idrija near the border with Italy.

The Sava-Drava Region. Emerging from Alpine Yugoslavia, the Sava on the south and the Drava on the north descend through the Slovenian hill country to the plains, ultimately converging on the Danube. Before leaving Slovenia, the Sava passes close to that republic's thriving capital, Ljubljana. Ljubljana's wealth and that of many other towns of Slovenia can be traced to the industrialization of the region, a development that was at least partially dependent on minerals that are extracted nearby: iron mined near Ljubljana, lead and zinc at Mežica, and lignite at Velenje.

Soon after entering Croatia, the Sava flows past Zagreb, the republic's capital and industrial center. The Sava and the approximately parallel course of the Drava to the north then enclose the plains of Slavonia. Farther to the east the Danube, which is joined by the Drava east of Osijek, and the Sava frame the region of Srem. These fertile alluvial plains form one of Yugoslavia's main agricultural areas. Remnants of the ancient Pannonian platform appear as outcrops and ranges, forming an interfluvial divide paralleling the river.

The region is Yugoslavia's main transportation corridor for both roads and railroads. This dense transportation network links the three major cities of Ljubljana, Zagreb, and Belgrade

(which lies at the eastern end of the region) and serves these and other important industrial cities along its route. Belgrade, at the confluence of the Sava and the Danube, is the capital of the country and of the republic of Serbia. It is also Yugoslavia's major manufacturing center and the hub of its communications network. Due to the region's natural advantages and historic importance, Yugoslavia's population is concentrated in the territory running generally from Zagreb to Belgrade.

The Trans-Danubian Pannonian Basin. The land of the Pannonian basin, lying to the east and north of the Danube River and comprising all of Vojvodina, is an extension of the Great Hungarian Plain, or Alföld. It is traversed from north to south by the Tisa (Hungarian, Tisza) River, a tributary of the Danube. The region known as the Bačka is to the west of the Tisa; the Yugoslav part of the Banat, to the east of the Tisa.

This region contains Yugoslavia's richest agricultural lands. It produces half the country's bread grains, half the corn, 85% of its sugar beets, and over 80% of its vegetable oils.

The fertile soil of the area includes rich alluvium deposited by rivers, loess borne by winds from the Alföld to the north, sediment from what were once lakes, and humus created by decaying grasses. In places where extensive sand dunes have developed in the drier areas, trees and grasses have established themselves. Marshlands in the floodplains have been drained to expand areas under cultivation and dikes built to check flooding. Canals are used for both barge traffic and irrigation.

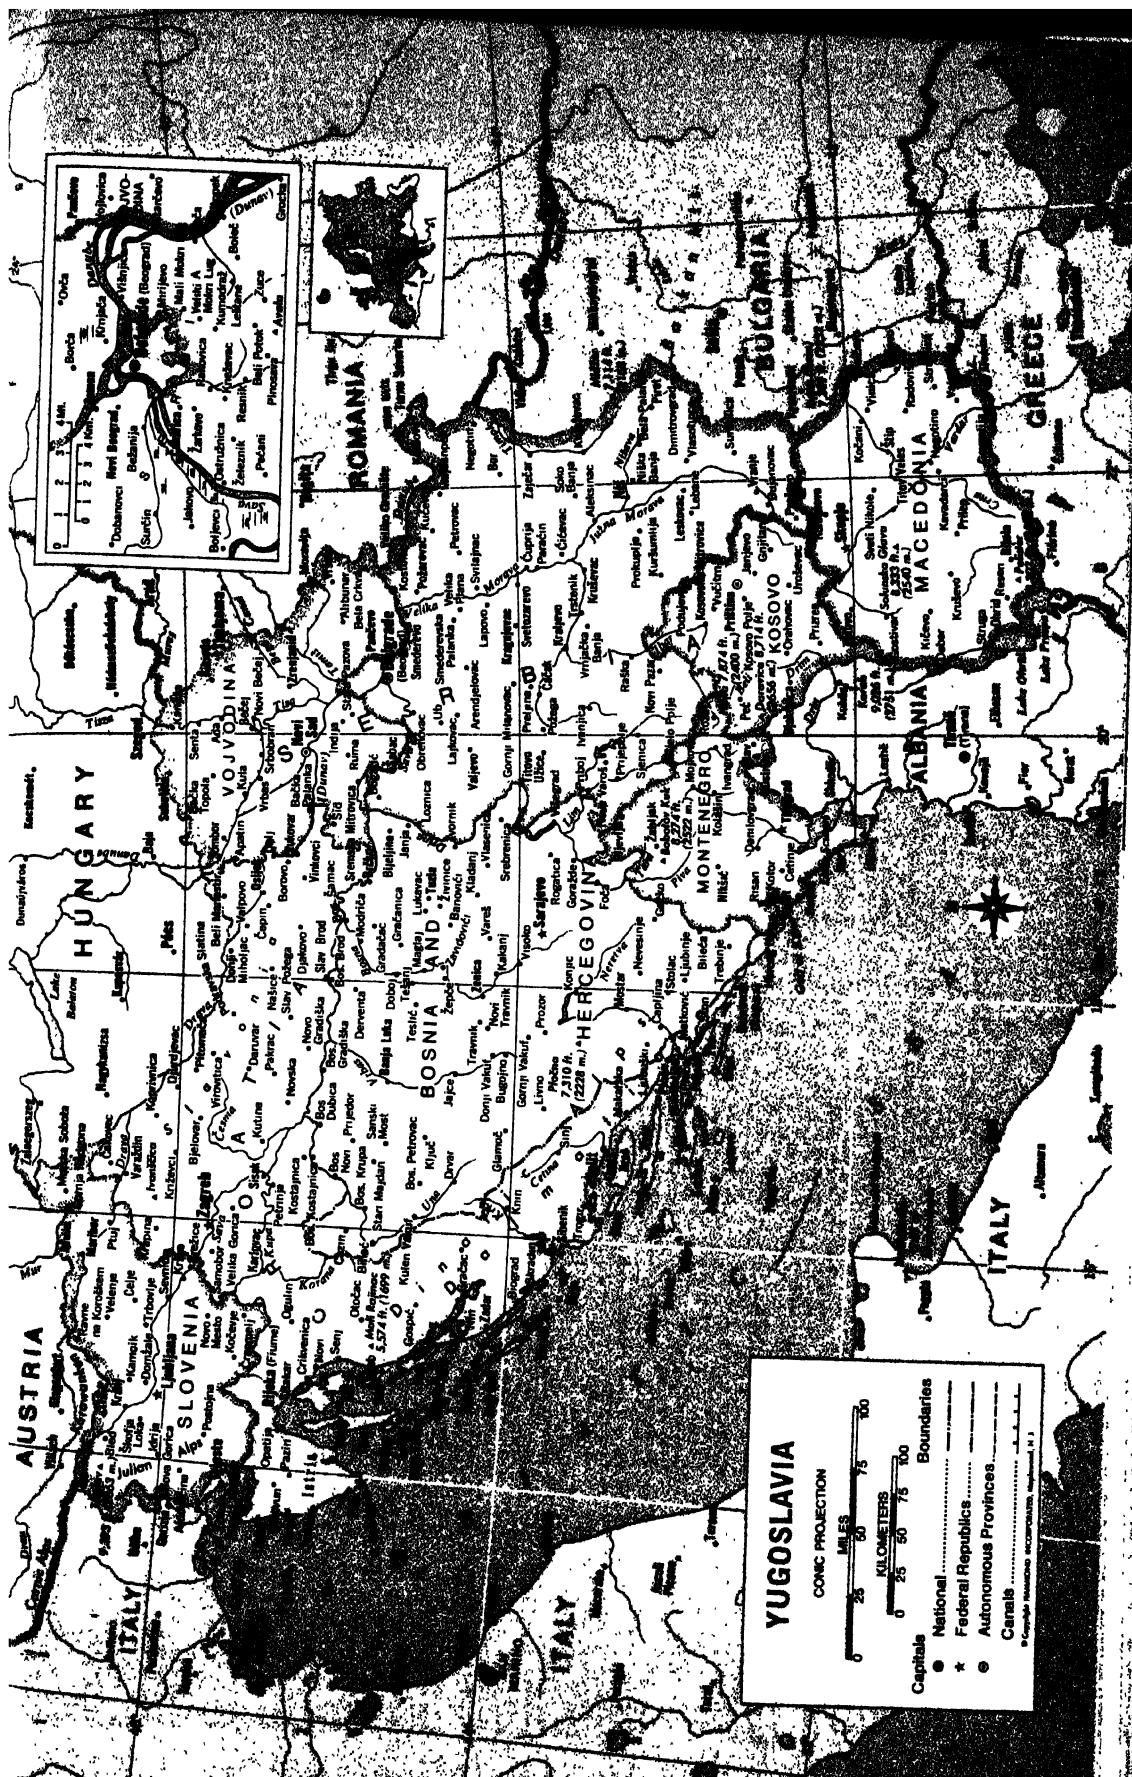

The processing of the agricultural products of the region and the manufacture of farm machinery are major industrial activities of the region's major cities—Novi Sad (the capital of Vojvodina), Subotica, and Zrenjanin.

Explorations beginning in the late 1950's also located substantial reserves of petroleum and natural gas in the Pannonian basin. When the fields were put into production, Novi Sad was made the center of production, and oil-related industries have been developed there.

The Morava-Vardar Corridor. The Morava River, formed by the junction of its two branches, the Western Morava and the Southern Morava, flows northward through central Serbia and discharges into the Danube east of Belgrade. The Vardar River flows southeastward through Yugoslav Macedonia before entering Greece on its way to the Aegean near Salonika. The Southern Morava and the Vardar rise only a few miles apart, near Skopje, Macedonia's capital, and their headwaters are separated by a relatively low watershed.

To the east of the Morava is an arc of mountains, part of the Balkan Mountain (Stara Planina) system. To the northeast, across the border in Romania, are the Transylvanian Alps. The Danube forces its way between these mountain systems in several narrow gorges. In 1972 a dam built by Yugoslavia and Romania was completed at the lowest defile, known as the Iron Gate. Copper is mined in the Balkan Mountain area near Majdanpek and Bor; Bor has one of the greatest copper reserves in Europe. Lignite is mined in the upper Timok Valley.

Just south of the curve of mountains as they enter Bulgaria is the city of Niš, standing athwart a natural corridor between Sofia, Bulgaria, and

the Morava Valley. Used in the past by migrating peoples and invaders moving between Anatolia and the Danube, this route is now followed by a major rail line between Istanbul and Belgrade.

Niš is located on the Nišava, a tributary of the Southern Morava. It is this southern branch of the Morava that forms the main corridor with the Vardar.

The region to the west of the Morava and extending south from Belgrade is known as Šumadija. In the early 19th century, Šumadija and its principal town, Kragujevac, was the center of Serbian nationalism. Šumadija is almost as densely populated as the Morava Valley region between Belgrade and the basin of Niš. These fertile areas, hot in the summer, are generally planted with corn and wheat. They are particularly famous for their plums and plum brandy (*sljivovica*). The whole of the Morava Valley is also being industrialized, and the location of industries is determined in part by the region's mineral resources.

The Šumadija is bounded on the south by the Western Morava. The Western Morava's major tributary, the Ibar River, joins it from the south, after flowing between the Kopaonik massif on the east and the Raška district (the core of the medieval state of the Nemanya dynasty) and its chief town, Novi Pazar, on the west. Further upstream on the Ibar, at the southern foot of the Kopaonik massif, is Yugoslavia's largest lead mine at Trepča.

The Ibar rises in the Mokra Planina, which forms the northwest boundary of the largely Albanian-settled area known as Kosovo. There are two major basins in Kosovo: the *polje* of Kosovo near Pristina and that of Metohija near Prizren. The Kosovo *polje*, which provides an alternative Vardar-Morava route between the Aegean and Belgrade by linking the two river valleys via the Ibar and the Western Morava, was the setting for two great Ottoman victories (1389 and 1448).

The boundary between Kosovo and Macedonia is marked by two massifs, the Šar Planina and the Crna Gora. But Yugoslav Macedonia's most rugged terrain and highest mountains are found near its border with Bulgaria on the east and Albania on the west. The major basins in the republic are those of Skopje, Tetovo, to the west of Skopje, and Bitola in the south. Lakes have formed in the basins of Prespa on the border with Greece and Albania, and Ohrid on the border with Albania.

The Vardar River begins its southeastward course at Skopje, cutting its way through the crystalline rock in deep valleys. The land it drains receives less rain than central Serbia, and irrigation is necessary for the cultivation of rice, cotton, and tobacco. Grapes, figs, and almonds are grown in the more Mediterranean areas of the southeastern section of the republic. But agricultural possibilities have been limited because of widespread erosion that has resulted from earlier clearing of the forests and overgrazing.

The mineral resources of Macedonia include lead and zinc in the northeast, chromium in the north near Skopje, and iron ore in the west central part. Iron and steel, metallurgical, chemical, engineering, and textile industries are concentrated in the Skopje basin. The building of iron and steel plants in the region of Skopje is an example of modern attempts to disperse industry to poorer areas.

2. The People

After its birth as a multinational state in 1918, Yugoslavia had to confront conflicts and antagonisms among its constituent national groups. And after World War II the people themselves were changed in fundamental ways as a result of the rapid industrialization and urbanization of the country. In addition, the structure of Yugoslav society was profoundly altered by the replacement of the monarchy with a one-party Communist state.

National Diversity. A federation of peoples, Yugoslavia contains no "Yugoslav nation" as such, although it is possible to declare oneself a Yugoslav in the census. The country defines national identity by language, religion, ethnic affiliation, and history.

The state recognizes six major "nations," or peoples, of Yugoslavia—Bosnian Muslims (9% of the total population), Croats (20%), Macedonians (6%), Montenegrins (2.5%), Serbs (36%), and Slovenes (8%). These are all South Slavs. The "nationalities," or minorities, of Yugoslavia consist of Albanians, Bulgarians, Czechs, Hungarians, Italians, Romanians, Ruthenians, Slovaks, and Turks, all of whom enjoy certain recognized national rights. There are also Austrians, Germans, Greeks, Gypsies, Jews, Poles, Russians, Ukrainians, and Vlachs in Yugoslavia.

When established in 1918, the first Yugoslav state was called the Kingdom of the Serbs, Croats, and Slovenes, with only these three peoples receiving full recognition. The inhabitants of Macedonia were treated as Serbs, as were, with greater justice, the Montenegrins.

The Serbs have played the leading political role in Yugoslavia but one that often has been bitterly contested by the other peoples. The Serbs have a strong historical tradition of independent existence. In the 12th to 14th centuries, before succumbing to the Ottomans, they had a powerful kingdom that controlled large areas of the Balkans. Falling under Ottoman hegemony after the Battle of Kosovo in 1389, they were ruled through the Orthodox Church and by their own notables. During the Ottoman period many Serbs emigrated to lands in the Habsburg empire. Thus, by 1918 the Serbs formed a portion of the population of Dalmatia, Croatia, Slavonia, and of the lands that later were to constitute Vojvodina.

The Croats have a similar history of autonomous or independent existence. Living mostly in Croatia, Dalmatia, and Slavonia, they orga-

nized an independent kingdom in the 9th century. Joined with Hungary from 1102 until 1526, when Hungary was crushed by the Ottoman armies, the Croatian kingdom subsequently came under Habsburg rule.

The national development of the Slovenes occurred within the Habsburg empire. A prosperous peasant people, they had a generally higher standard of living than other South Slavs. Their language, not readily intelligible to Serbo-Croatian speakers, separated them from that majority of Yugoslavs.

Whereas the first Yugoslav government based its political structure on these three peoples, the postwar Communist government recognized the unique historical and national characteristics of five other groups—in Bosnia-Herzegovina, Macedonia, Montenegro, Kosovo, and Vojvodina. Of these, Bosnia-Herzegovina is the most complex area. Although inhabited by Serbo-Croatian-speaking South Slavs, the republic is divided on religious and cultural grounds. Bosnian Muslims, considered a separate "nation" after 1945, form about 40% of the population of the republic; Serbian Orthodox, over 30%, and Croatian Catholics, nearly 20%.

Macedonia, which the interwar government had attempted to treat as Serbian, was organized on its own national basis in 1945. Contesting the control of the area with Bulgaria, the Yugoslav government recognized a separate Macedonian language, which became standardized, and attempted to define a Macedonian historical and literary tradition apart from that of either Serbia or Bulgaria.

Although Montenegro also had been regarded as Serbian, the Montenegrin population was recognized as a separate "nation" in 1945. The Montenegrins had retained a consciousness of their distinctive political identity, based on their history and their existence in an independent state after 1878. Their special status was also related to Montenegro's importance as a center of

resistance to Italy and Germany during World War II and to its role in the Communists' victory during the civil war after the Axis occupation.

The two autonomous regions of Serbia were created after World War II as a means of dealing with the problems associated with the Hungarian and Albanian minorities in Serbia. Of more than 20 ethnic groups living in Vojvodina, Serbs form a slight majority of the population; Hungarians, nearly 20%; and Croats, Slovaks, Romanians, Montenegrins, and Ruthenes, each between 6% and 1%. To deal with the area's multinational complexity, and especially to meet Hungarian grievances, five languages were recognized—Serbo-Croatian, Hungarian, Slovak, Romanian, and Ruthenian. These became the languages of major journals and newspapers, of radio and television stations, and of schools for classroom instruction. Although conflicts did occur, the linguistic policy in Vojvodina was generally considered a success.

Matters were quite different in Kosovo. There, Albanians—a Muslim group with the highest birthrate in Yugoslavia—form about 90% of the population. Most of the rest of the inhabitants are Serbs or Montenegrins. The majority of Yugoslav Albanians live in Kosovo, but some reside in Macedonia and Montenegro. Since many have been attracted to neighboring Albania, a state that in most of the postwar period was strongly opposed to Yugoslavia, the problem of the Albanian minority has been a matter of serious concern for the Yugoslav government.

Although great efforts were made to deal with ethnic antagonisms through the organization of the republics and the recognition of national rights, basic cleavages remained. The religious and cultural traditions of the Croats and Slovenes

differ from those of the Serbs, Montenegrins, and Macedonians. The Muslims in Bosnia-Herzegovina, Macedonia, and Kosovo have yet another religious and cultural orientation. It should be noted that among the Muslims only Serbo-Croatian-speaking Bosnian Muslims, not Albanian or other Muslims, were recognized as a separate people. In addition, past events had caused distrust between certain groups, in particular the Serbs and the Croats. A further disturbing factor was the extreme contrast in economic development between the poor, underdeveloped republics of Macedonia, Montenegro, and Bosnia-Herzegovina and the relatively prosperous republics of Slovenia and Croatia. After 1945, national passions and jealousies continued to play a major role in Yugoslav life, with each national group asserting its rights.

The problems associated with national diversity and a heritage of historic antagonisms were recognized by the postwar Communist government. Even though in Marxist doctrine nationalism was a passing historical phase, Socialist theory called for an initial period of national self-expression. Therefore, although the government emphasized socialism as the chief unifying force, it also acknowledged the many positive values of nationalism. Throughout the country the various peoples and minorities had their own newspapers, societies, theaters, orchestras, and, usually, the opportunity for education in their own language and for jobs in which their language could be used. But when the government deemed a nationalist manifestation to be a danger to the unity of the country or to control by the Communist party, it intervened. Such was the case with national demonstrations by the majority group in Serbia in the late 1960s, in Cro-

atia the early 1970s, and in Kosovo in the 1980s.

National Integration. During the period following World War II, forces for unity were strengthened at the expense of those for diversity by way of the modernization of the economy and the increasing movement of people within the country and in travel abroad. Before 1945 the regions of Yugoslavia, particularly in the rural areas, differed in dress, cooking, and manner of life. Afterward, although contrasts remained, urbanization, modernization, and industrialization leveled the way the majority lived and worked. Communist economic planning meant standardization in clothing, furniture, and housing. The new housing for the urban working population reflected styles found throughout the industrial world in the familiar pattern of massive block buildings and congested suburbs. Some attention was given to the preservation of historic buildings, both to maintain national heritages and to attract tourists, but a growing uniformity of appearance became apparent.

A large section of the population also either traveled or worked abroad and thus was well aware of cultural change and fashions in the rest of the world. The young in particular were taken by Western styles, especially in clothes and pop music. Thus, blue jeans and rock music, not peasant costumes and traditional songs, characterized the tastes of the rising generation. In addition, theater, domestic and foreign movies, and, in particular, television promoted uniformity and similarity.

Social Structure. From 1918 until after World War II, the Yugoslav state had a predominantly agricultural population: 79% of the total in 1921, 75% in 1938. Even though new industrial enterprises were established in the interwar period, the basic nature of the agrarian state was not changed. After 1945, as the Communist leadership devoted its energies to rapid industrialization, the agricultural sector was neglected. Yugoslavia underwent a social revolution marked

by a sharp decline in the strength and influence of farming. Whereas the agricultural population in 1945 was still more than 70% of the total Yugoslavian population, this figure had plummeted to 29% by 1980.

In the interwar years the state was controlled by a small group that was closely associated with the royal court, with business, or with the army, or who were among the wealthier members of the business community and the professions. The dictatorial nature of the regimes in power excluded the great majority of workers and peasants of all national groups from participation in the political life of the country.

Marxist theory, on the other hand, promised a classless society—but at some time in the future. The Communist government, while effectively excluding those who enjoyed economic and political power before 1945, created its own hierarchy of social and political influence. At the same time, though, it greatly widened and increased the numbers of active and direct participants in the governing of the country.

The new social stratification within Yugoslavia reflected the political realities of Communist Party rule and the economic hierarchy. At the top could be found a small minority who held the major administrative positions in the state; the party, and the chief economic enterprises. The most important decisions in political and economic life were made by them. They enjoyed special privileges and a high standard of living. Below this group but still in the upper ranks were those who held lesser positions in the same areas. Also with high status was a professional middle class of doctors, lawyers, engineers, teachers, and others, some employed in state enterprises and some having private offices. Next on the scale were the skilled workers and the successful farmers, and below them were the unskilled workers. As before, the lowest position of all was occupied by the peasants and agricultural laborers.

Social Welfare. The Communist Party program called for the creation of a society of equal citizens provided with basic social services. Differences in income were indeed often considerable, but certain benefits were guaranteed to all. Each citizen was given health, disability, and unemployment insurance, and was also guaranteed a pension. This program was administered by the republics and by local administrations. Employees' wages, hours, and vacations were set by the enterprises or institutions for which they worked. Under the principles of workers' self-management, the individual was meant to play some part in making the decisions connected with such matters.

Although each citizen did enjoy these social benefits, criticism was leveled at many parts of the program. Among the major defects singled out were the low level of retirement benefits and the poor quality of health care in public institutions.

Population Changes. Yugoslavia's population decreased dramatically in the 1940s as a result of enormous wartime losses, estimated at between 2 million and 3.25 million. Immediately after the war the population total was further reduced when members of certain groups—including Germans, Austrians, Italians, and Turks—were compelled to emigrate because of their wartime activities. Afterward, however, the population showed a marked rise.

© DR. HANS KRAMARZ

Such groups as this national youth brigade draw together Yugoslavs from all of the republics.

The improved health services introduced by the Communist regime caused a conspicuous drop in the mortality rate, but the birthrate fell even more rapidly. The result was a declining rate of natural increase, from an average of 2.8% a year in 1948–1953 to 0.9% a year in 1971–1981. Natural increase, varying widely among the republics and national groups, was lowest in economically advanced areas such as Slovenia and Croatia, and highest in impoverished areas such as Kosovo and Macedonia. Considerable attention was paid to the relative numerical strength of the national groups. Thus the 24% population increase for Kosovo between the 1971 and 1981 censuses had strong political repercussions.

Postwar Yugoslavia was characterized by large movements both within the country and to other countries. The most important internal migration was the shift from the countryside to the cities. In addition, workers from the poorer sections of the country migrated to the richer areas—for example, from Bosnia-Herzegovina to Slovenia and Croatia. Usually without specialized training, they were hired chiefly as unskilled labor.

Most of the emigrants from Yugoslavia left to work in the expanding and prosperous industrial areas of Western Europe, in particular West Germany. Unlike previous emigrations, this new wave came for the most part from the wealthier republics and was composed of skilled and highly motivated workers or professionals, who sought economic and social advancement. But, except for those who emigrated permanently, many of the workers who had left the country began to return in the late 1970s as worldwide recession forced a general economic contraction in all the host countries.

3. Education

The regions that were joined together in a unitary state in 1918 varied widely in the extent and quality of their educational systems. A major problem for the new country was the degree of illiteracy, more than 51% in 1921. Regional

differences were most apparent: only 9% of the Slovenes were illiterate, contrasted with 84% of the Macedonians. The interwar government made an effort to correct this state of affairs and also to provide better schools for the country. In 1940, nevertheless, the overall illiteracy rate was still about 40%.

Recognizing the vital importance of an educated population for a modern industrialized society, the government after 1945 attempted to improve matters. Education was made compulsory for eight years, for children between the ages of 7 and 15. For older students, various institutions of secondary education became available, including technical schools, teacher training schools, and classical gymnasia with studies designed to prepare students for entrance to a university. The major universities came to be those in the republican and provincial capitals—Belgrade, Zagreb, Ljubljana, Sarajevo, Skopje, Titograd, Novi Sad, and Priština. In 1950 the administration of educational institutions was decentralized.

Despite major efforts at raising the educational level, 15% of the population was still illiterate in 1971. The rate of illiteracy ranged from 1% in Slovenia to 32% in Kosovo. Adult-education programs were developed to spread reading ability and to teach additional skills to workers. By the 1981 census, illiteracy had declined to 9.5%.

A characteristic of the Yugoslav system was the inclusion of multilingual education, which, however, continued to provoke controversy and complaint. Classes were taught in the dominant language of the republic; but where a minority formed a large percentage of the population, teaching was conducted in the minority's language, and courses were offered on its history and cultural heritage. Vojvodina, with its five languages, was the best example of this principle in operation. However, a mastery of Serbo-Croatian was necessary for advancement to high-level positions in the state, party, and economic enterprises.

The palace of the Roman emperor Diocletian made Split a major cultural center of Yugoslavia.

4. Culture

Just as there has been no historic Yugoslav nationality, so there has been no single cultural tradition. The land thus reflects, on the one hand, the influence of the differing religions and cultures introduced through foreign occupation, and, on the other, the unique folk traditions of the individual regions. The heritage of Islam and Ottoman occupation is apparent in cities such as Bosnia's Sarajevo and Hercegovina's Mostar and in buildings such as the fortress of Kalemegdan, now a park in Belgrade. The Catholic-Habsburg past is mirrored in the baroque architecture in Slovenia's Ljubljana and Croatia's Zagreb. The spirit of Serbian Orthodoxy is seen in the monasteries and churches of Serbia and in sections of the older part of its cities. Along the Adriatic, Roman and Venetian rule are repeatedly recalled by the architecture of the port cities and of ruins such as that of Diocletian's palace in Split.

Although the peasant culture is fast disappearing, regional differences can still be seen in domestic architecture (particularly in the countryside), in the food, and sometimes in the dress. Attempts have been made to preserve some of the handicrafts. Ethnographic museums collect and display examples of this work, especially embroidery and wood carving, and folk music has been recorded to assure its preservation as part of the heritage of each national group. Buildings of historical significance, such as churches, mosques, and monasteries, have likewise been restored.

Literature has a particular significance for the Yugoslav national groups because of its role in shaping the individual cultures and in promoting the national revivals of the 18th and 19th centuries. Of major importance for each movement was the development of a standard literary language. Previously, Church Slavonic was the standard language for the Orthodox, and Latin for the Catholics. Since many of the clergy were trained in Russia, a Serbian literary language

emerged, known as Serbian-Slavic, which had a large percentage of Russian words. Writing in the early 19th century, two scholars, Dositej Obradović and Vuk Karadžić, challenged the use of this artificial form and proposed that the spoken language should be the basis of the literary language. Selecting as a standard a Hercegovinian dialect, Karadžić wrote a grammar and a dictionary.

Croatian writers were faced with a similar decision, though their difficulties were greater because their spoken language had three dialects. In the 1830s and 1840s the Illyrian movement in Croatia stressed the cultural and linguistic unity of the South Slavs. The movement's chief spokesperson, Ljudevit Gaj, proposed the adoption of the Hercegovinian dialect spoken by the majority of Croats. Hercegovinian was also the dialect chosen by Karadžić for the Serbs. The groundwork was thus laid for a standard Serbo-Croatian literary language, which would be used by Croats and Serbs in the Habsburg empire and by Serbs in Serbia and Montenegro. The language was, of course, written in the Cyrillic alphabet by Serbs and in the Latin alphabet by Croats.

In this same period the greatest Slovene poet, France Prešeren, and the prose writer Fran Levstik were influential in establishing standard Slovenian. This language is distinct from Serbo-Croatian but close to a dialect spoken in northern Croatia.

These authors were part of the Romantic school that dominated writing throughout Europe in this period. The Romantic movement fitted in well with rising Balkan nationalism. Among the Serbs the greatest writer was the poet prince-bishop of Montenegro, Petar Petrović Njegoš (Peter II), whose major work *Gorski Vijenac* (*The Mountain Wreath*) is a masterpiece of Serbian poetry. In Croatia the major writer was August Senoa, whose best-known work is *Seljačka Buna* (*The Peasant Uprising*). Another author, Ivan Mažuranić, wrote the epic poem

Smrt Small-age Čengića (The Death of Small Age Čengić).

Realism in European literature was also reflected in the South Slav lands. Svetozar Marković, a major realist, was in addition the founder of Serbian Socialism. Historical writing, too, was important in this period. The Serbian Slobodan Jovanović and the Croatian Ferdo Šišić composed major works on the history of their people.

Painters and sculptors, like the writers, followed European trends closely. Many studied in Paris, Munich, or Vienna. Among the artists, special mention should be made of Ivan Meštrović, a sculptor trained in Vienna, who worked in Yugoslavia in the interwar period but emigrated to the United States after World War II.

Among post-World War II writers, three in particular attracted international attention. Milovan Djilas, repeatedly imprisoned because of his bitter criticisms of the Communist regime (as in *Nova Klasa*, translated into English as *The New Class*), also wrote about his homeland, Montenegro, in such books as *Besudna Zemlja (Without Justice)* and *Njegoš (Njegoš: Poet, Prince, Bishop)*. In 1961 the Bosnian writer Ivo Andrić won the Nobel Prize for literature. He is best known for his descriptions of life in Bosnia, in such works as *Na Drini Čuprija (Bridge on the Drina)* and *Travnička Kronika (The Chronicles of Travnik)*. The major figure in Croatia was Miroslav Krleža, a prolific writer of plays, essays, novels, and short stories. Of his works that have been translated into English, the best known is *Povratak Filipa Latinovicza (The Return of Philip Latinovicz)*.

Yugoslavia's Communist government supported the expansion and development of the theater, opera, and ballet. The republics devoted much attention to the production of radio and television programs and to the making of movies. Documentary and feature films were produced, and animated films made in Zagreb achieved a worldwide reputation.

5. The Economy

Since the founding of the Yugoslav state, all parties and leaders have sought to resolve the economic problems of the country through industrialization and modernization. But they have differed radically on the best means to achieve these goals.

The first task after 1918 was to rebuild the part of the country that had been devastated by World War I. Immediate attention also had to be given to the peasants' demand for land reform. Thus the large estates were divided, particularly in the former Habsburg lands, where they were often in the possession of enemy nationals.

In the interwar years Yugoslavia was a land of small peasant farmers, with about 75% of the population directly dependent on agriculture. Most of the farms provided only a bare subsistence for their owners, and the countryside was impoverished and backward.

The royalist government used subsidies and tariffs to advance the country's industrialization. It also owned certain enterprises; ran the telephone, telegraph, and radio networks; and held monopolies on salt and tobacco. The major industries in the interwar period were those closely related to agriculture, such as milling, sugar refining, alcohol distilling, and food processing. The textile, timber, woodworking, metallurgy,

and chemical industries were also important. The Bor copper mine and the Treptča lead and zinc mines were exploited. In foreign trade the chief exports were wheat, maize, hogs, lead, zinc, copper, timber, and hemp. After 1936, Germany was Yugoslavia's major trading partner.

World War II and Yugoslavia's civil war once again caused tremendous devastation. Not only did extensive areas need rebuilding, but with the victory of the Communist Party, plans were made to reorganize the economy along radically different lines. Following the precepts of Marxism-Leninism and, at first, adhering to the Soviet model, the new Communist government gave top priority to rapid industrialization. The factory workers in the highly industrialized state that was envisaged were to supply the basic support for the new regime.

From 1946 to 1948 a Stalinist pattern of economic organization and development was followed, with the chief emphasis on heavy industry and centralized planning. But after breaking with the Soviet Union in 1948, Yugoslavia's leaders adopted policies that were unique in the Communist world. Contending that there were different roads to socialism, they attempted to introduce patterns of organization that better fitted the character of their state and that allowed a greater degree of decentralization in the national economy.

In June 1950 the National Assembly passed a law that was to have the greatest significance for the future. Entitled "Management of State Economic Enterprises and Higher Economic Associations by Workers' Collectives," this measure introduced the idea of workers' self-management, an original contribution by Yugoslavia to socialism. In theory the state did not control the factories and other means of production. These were considered "social property." Each firm was to be run by workers' councils, elected by the employees of that firm. The director or manager of the firm, with whom the management board of the workers' council was supposed to work closely, was chosen by a commission with state and party representation.

A federal planning bureau continued to draw up a national economic plan, as did the individual republics and the lesser administrative units. These plans, however, were intended to be only advisory in nature.

Beginning in the mid-1960s, the government embarked on a policy of economic decentralization, with due attention given to market forces. Basic decisions were meant to be made by the individual enterprises, which were supposed to make a profit. Wages were to a degree dependent on profits. However, a struggle continued between those who favored a return to a more centralized economy and those who preferred the situation as it was or who called for even further decentralization.

Agriculture. Despite the postwar government's increasing emphasis on industrialization, agriculture continued to play a major role in the economy. Much of the country had a daunting terrain, and yet 58% of the land was used either for crops or for pasture.

The Communist regime modified the Soviet model of agricultural organization and differed with the Soviet Union on the basic issue of land ownership. However, immediately after World War II, the government attempted to force the peasants into collectives and state farms. Peas-

ant resistance then led to the abandonment of forced collectivization and the breakup of most of the collectives. After 1953 the small, independently owned farm was reinstated, with a limit of 24.7 acres (10 hectares) placed on individual holdings except in mountainous or hilly country.

A serious effort was made to modernize agricultural techniques, increase mechanization and the use of fertilizers, and introduce improved seeds and livestock feed. The establishment of cooperatives gave individual farmers the advantages that were usually associated with large agricultural enterprises. Also, the cooperation between the state and private agriculture was considerable.

The one sixth of the farmland that was not in private hands was organized into *kombinats*, which functioned under the same principles of self-management as those adopted by industry. The large size of the *kombinats* (60% of the socialized land was organized into units of more than 12,350 acres, or 5,000 hectares) made possible the efficient use of machinery and technological advances.

Agricultural production expanded, but farming suffered from the emphasis placed on industrial development. One result was a lack of investment in the private farms that was needed to increase their efficiency. Moreover, many young men moved to the cities, leaving behind an aging and diminishing peasant population. Bad organization of the agricultural sector also resulted in unbalanced pricing and uneven distribution.

The major crops were maize (corn), wheat, sugar beets, sunflower seeds, fruit, rice, potatoes, tobacco, cotton, and soybeans. But the wheat grown was insufficient to satisfy domestic needs and had to be supplemented by imports. Of the fruit crop, apples and plums were particularly significant in both the domestic and foreign markets.

Meat figured even more prominently than crops in the country's agricultural exports. More often than not, livestock were fed on fodder rather than pastured on grazing lands, which were freed for conversion to other, more profitable agricultural uses.

Lumbering. With more than 30% of its area in forest, Yugoslavia ranked just after the Scandinavian lands and Austria as the most heavily forested country in Europe. Almost three quarters of the standing timber was hardwood, primarily oak and beech. Because the hardwoods were less suited to industrial processing than the softwoods, the state increased softwood plantings. It also aimed at reducing felling to a point below annual increments in the tree stands. In addition, it opened remote areas for logging in order to spare the more accessible forests that had been severely overlogged. The fact remained, however, that many forests were inaccessible, making it impossible to get the lumber out.

Mining. Yugoslavia's mountainous terrain has endowed it with a variety of mineral resources, and at least in nonferrous metals the country has been one of Europe's leading producers. In percentage of world production, the most important minerals after World War II were magnesite, lead, bauxite, antimony, copper, and zinc. The extraction of nickel, chromium, and mercury was also significant. Industrialization, however, was hampered by inadequate supplies of iron ore and by the low iron content of the ore that existed.

Consequently, Yugoslavia had to continue to import iron ore.

The primary fuel produced was coal, chiefly in the form of lignite, although brown coal also was mined. The production of crude oil and natural gas became significant after World War II, and exploration for new reserves was carried out in the Pannonian Basin and on and off the Adriatic coast.

Energy. Because Yugoslavia was intent on industrialization, shortages in energy resources presented a fundamental problem for its postwar economic planners. The country did not have a sufficient supply of high-grade coal suitable for steel production. Furthermore, Yugoslavia produced only a small percentage of the petroleum and natural gas it needed. Therefore, it had to import both bituminous coal and crude oil, which combined made up a large percentage of its mineral imports. Natural gas was brought in by pipeline from the USSR.

With domestic energy resources insufficient, hydroelectric power was developed. One project was a hydroelectric station at the Iron Gate gorge on the Danube. The major hydroelectric plants were, however, situated in the mountainous regions of Serbia and Bosnia-Herzegovina, relatively far from industrial centers. Moreover, an energy system based on water could be no more dependable than the source of the water, namely rainfall, which in Yugoslavia varies greatly from year to year. Droughts have led to a loss of electric power that has affected industrial production and living standards.

Manufacturing. Yugoslavia's primary economic goal after World War II was more rapid and extensive industrialization, with the introduction of modern technology throughout the industrial sector. The manufacture of metal products—particularly motor vehicles and various types of engines—came to be one of the country's chief industries. Shipbuilding also formed an important element in this sector. The textile industry, though dependent on imported raw materials and operating with outdated machinery, contributed significantly to Yugoslavia's exports. The chemical industry grew at a faster rate than any of the other industrial sectors; and as domestic crude oil was extracted, the development of petrochemicals was given a high priority. Food processing profited from the gradual modernization of facilities and equipment. Electrical industries grew rapidly as the needs of both industry and consumers for electricity and electrical equipment increased. The expansion of the wood industry fluctuated with changes in consumer buying power, particularly in such branches as furniture veneer, joinery, and lumber. Nevertheless, its long-term growth was fairly steady.

Both ferrous and nonferrous metallurgy made impressive gains because of the attention given to capital-goods industries. Yet domestic steel and copper production fell short of demand, with the result that these metals had to be imported. The output of most nonmetallic mineral products, such as tiles, bricks, asbestos goods, and rock salt, was sufficient to meet the country's needs, but cement production frequently did not keep up with demand.

In advancing the industrialization of the country, the state was under pressure from the poorer republics, such as Macedonia, Montenegro, and Bosnia, to introduce more heavy indus-

try in their areas. In trying to satisfy these demands, the Communist government built "political factories" in the backward regions—factories that made little economic sense because they did not improve either a particular industry or the overall economy.

Labor. As a heritage from its impoverished past, post-World War II Yugoslavia suffered from an oversupply of unskilled labor with no tradition of disciplined factory work. Skilled workers were in short supply; yet it was precisely this group that tended to emigrate, in particular to West Germany, where wages were higher and working conditions were better. At one time, close to 20 out of every 100 workers held jobs outside the country.

Because of the importance of workers to the economy and the political system, both the Communist Party and the government were concerned with the workers' well-being. Although the single labor organization, the Confederation of Trade Unions of Yugoslavia, was dominated by the party, Yugoslav workers did strike; and, in contrast to other Communist countries, the government tolerated these actions.

Despite the attention to their needs, Yugoslav workers suffered along with the rest of the nation whenever there was a general decline in the economy. In periods of inflation, wages did not keep pace with rising prices.

A significant number of Yugoslavs worked outside the state-controlled section of the economy, contributing to a "second economy." It was not uncommon for an individual to hold two jobs, one in a state enterprise and another in the private sector. The Communist government allowed small private enterprises employing up to five persons or staffed by family members. Thus many restaurants, bars, and barber shops were privately owned. Artisans, such as makers of shoes or handbags, often owned their shops. Plumbers, electricians, and mechanics also found private employment; in addition, professionals, such as lawyers, doctors, and dentists, could have private practices.

Transportation. Yugoslavia's railroad network was rebuilt and expanded after World War II. However, development of the system was hampered by the great cost of building new track through the difficult terrain. The major line runs southeast from the Austrian border near Jesenice to Belgrade, via Ljubljana and Zagreb. From Belgrade it continues south to Skopje and Greece, with a branch from near Niš traveling southeast to Bulgaria and Turkey. Belgrade and Zagreb are also connected by rail to Hungary, and Belgrade to Romania. Other lines serve the Adriatic coast. A railroad with feeders from Ljubljana and Zagreb connects Italy with the ports of Rijeka and Split. Another line runs from the Zagreb-Belgrade trunk route to Sarajevo, then through the Neretva Valley to the port of Ploče. A railroad also links Belgrade with the Adriatic seaport of Bar.

In general, the major highways parallel the railroad lines. The vast increase in the use of trucks for shipping goods and in the quantity of automobile traffic confronted the government with the need to improve the road network. Priority was given to industrial and tourist areas. Even though an ambitious nationwide program was adopted and foreign loans were obtained for some of the construction, Yugoslav highways remained inadequate to handle the heavy interna-

Rijeka became Yugoslavia's leading port partly because of its superior land connections with the interior.

tional traffic that passed through the country—particularly from central Europe through Belgrade to Istanbul, in Turkey.

Yugoslav Air Transport (JAT) was developed as the principal Yugoslav airline, with both domestic and foreign service.

The Danube is navigable for its entire length within Yugoslavia, and its major tributaries—the Sava, Drava, and Tisa—are navigable for at least part of their lengths. Therefore, they have played a major role in internal transportation. With the exception of the Neretva, which is navigable for a short distance from Metkovic to the sea, the Dalmatian and Macedonian rivers cannot be used for transport.

Foreign Trade. In attempting to industrialize and modernize the economy rapidly, Yugoslavia had to import technology and capital goods, as well as basic raw materials and energy resources that it lacked. As a poor country, it needed outside assistance, particularly loans. After its break with the Soviet Union in 1948, Yugoslavia turned to the Western powers. The United States and the European Communities (EC) gave the needed aid, at least in part, in order to ensure that Yugoslavia maintained its independence of the USSR. After 1955, relations with the Soviet bloc improved. In 1964, Yugoslavia began to participate in the activities of the bloc's economic association, the Council for Mutual Economic Assistance (Comecon), but it did not become a full member. Credits were also obtained from this source. Despite efforts to improve trade, Yugoslavia ran up a large debt and suffered a chronically unfavorable balance of payments. In

the 1980s, service on its foreign debt absorbed 25% of the country's foreign exchange.

In the early 1980s, Yugoslavia's trade was primarily with the EC, particularly with West Germany and Italy. Slightly over a third was with Comecon countries, and somewhat under a fifth was with Third World countries.

Tourism. Beginning in the 1960s the Yugoslav government made a determined effort to promote tourism. This sector of the economy not only earned foreign exchange that the country needed but also provided work for the unskilled unemployed. The relative openness of Yugoslavia's society allowed foreign visitors to travel freely.

The Adriatic coast, with its mild climate and long series of beaches, was the main area developed for tourism. The Adriatic highway permitted cars to travel on a modern road from Italy almost to the Albanian border. Modern hotel complexes were built, and rooms in private homes became available.

Slovenia's Alpine areas also attracted tourists. And in 1984, Yugoslavia held the Winter Olympic Games in Bosnia's capital, Sarajevo, in an attempt to develop this area for tourism.

HISTORY AND GOVERNMENT

The Yugoslav state formed in December 1918 was composed of the territories of prewar Serbia and Montenegro, both of which had been independent states, and of Bosnia, Hercegovina, Dalmatia, Croatia, Slavonia (including Srem), Bačka, a small part of Baranja, and part of the Banat, all of which had belonged to Austria-Hungary. In addition, lands inhabited by Slovenes were annexed; Austria also claimed some of these lands, and in the final settlement that followed a plebiscite, Austria kept the Klagenfurt area. The bitterest conflict, however, came over Yugoslavia's border with Italy. That state was able to annex from Austria-Hungary the Küstenland (Görz-Gradisca, Trieste, and Istria), with a large South Slav population, in addition to some Dalmatian islands, the Dalmatian mainland city of Zara (Zadar), and later the major port of Fiume (Rijeka).

The joining of the South Slavs of the Habsburg monarchy with those of Serbia and Monte-

negro was made possible by the Allied victory in World War I. It was also the expression of the desires of those who supported the "Yugoslav Idea"—that the Serbs, Croats, and Slovenes were one people, who should form a single state. Although supported by only a minority, chiefly students and intellectuals, this concept became a reality largely because of the particular conditions prevailing at the end of the war. During the conflict a Yugoslav Committee, composed of émigré politicians from the Habsburg empire, had entered into negotiations with the Serbian government-in-exile on the Greek island of Corfu. In July 1917 a declaration was issued asserting the intention of creating a state composed of Serbs, Croats, and Slovenes, organized on a federal basis, with the Serbian Karadjordjević (Karageorgevich) dynasty at its head.

In the last months of the war, as the Habsburg empire collapsed into its national components, a National Council of Slovenes, Croats, and Serbs was formed in Zagreb. In November 1918 it declared its intention of uniting with Serbia. The Habsburg South Slavs feared that if they did not act, Italy would annex large sections of their territory. In the same month a Montenegrin national assembly also voted to join a union. On December 1, in Belgrade, representatives of the Habsburg South Slavs requested Serbian Prince Regent Alexander, acting for Serbia's King Peter, to proclaim the union. A new state, officially entitled the "Kingdom of the Serbs, Croats, and Slovenes," thus came into being.

6. Monarchical Yugoslavia

In order to administer the state until a constitutional assembly could be convened, a provisional government representing the various national groups and political parties was formed. In elections held in November 1920, two Serbian parties received the most votes: the Radical Party, which had been the prewar ruling party in Serbia, and the Democratic Party, which contained not only Serbs from Serbia but also former Habsburg Serbs and Croats who favored a centralized state. The Croatian Peasant Party, which was now the dominant Croatian party, and the new Communist Party both showed strength in the polls.

During the drafting of the constitution, considerable controversy was aroused by the government's insistence on a centralized administration. Before the final vote was taken, many delegates, including those of the Croatian Peasant and Communist parties, had withdrawn. Thus, in the final count only 258 out of 419 delegates voted, and of these only 223, representing a minority of the electorate, approved the final document. The constitution, adopted on June 28, 1921, established a constitutional monarchy. A unicameral legislature was to be elected by universal manhood suffrage. Under a highly centralized administration, the country was divided into 33 districts.

Parliamentary Government: 1921-1929. These troubled beginnings were to set the tone for the first years of the new state. Alexander, who became king in 1921, worked closely with Nikola Pašić, the major Serbian political figure from the prewar era, to maintain the centralized and Serbian-dominated regime. The task was not easy because the country was so divided: 43% Serbian, 23% Croatian, 8.5% Slovenian, 6% Bosnian Muslim, 5% Macedonian Slav, and 3.6%

Albanian, besides mixed minorities of other groups. Pašić attempted to solve his political problem by cooperating with the Radicals and Democrats and also by winning ^{political} support of two other groups: the Bosnian Muslims, represented by the Yugoslav Muslim Organization, and the Slovenes, through their major political organization, the Slovenian People's Party, which reflected the interests of this strongly Catholic and peasant people.

The major opposition came from the Croatian Peasant Party. Under the erratic leadership of Stjepan Radić, it continued to win the strong endorsement of the Croatian electorate. The Serbo-Croatian antagonism dominated the political scene and made orderly government almost impossible. The government met the situation by outlawing the Croatian Peasant Party; Radić and other leaders were given prison terms. In March 1925, in a reversal of position, the party announced that it would cooperate with the government. The leaders were then let out of prison. Some received ministerial appointments, and their representatives took their seats in the assembly.

The death of Pašić in December 1926 removed the major Serbian political figure from the scene. The political situation broke down entirely in June 1928, when a Radical Party delegate from Montenegro shot five representatives of the Croatian Peasant Party. Among these was Radić, who subsequently died of his wounds. Facing a period of extreme internal crisis, Alexander on Jan. 6, 1929, abrogated the constitution, abolished the political parties, and dissolved the assembly. His personal dictatorship was to last until his death.

The Royal Dictatorship: 1929-1934. Alexander had taken full control of the country. He was in command of the army, he chose the highest officials, and he kept political life under tight police power. Radically revising the administration, he also changed the name of the state from the Kingdom of the Serbs, Croats, and Slovenes to Yugoslavia. In an attempt to weaken national loyalties, he reorganized the country into nine districts (*banovine*), whose boundaries did not conform to the historic regions. Although he justified his actions as an attempt to generate a Yugoslav national feeling, the government in fact continued to be controlled by Serbs from Serbia.

In September 1931 a new constitution was issued that provided a political framework for the dictatorship. A bicameral legislature was created, with half the members of the upper house appointed by the king. The lower house was to be elected by universal manhood suffrage and by open ballot. The party receiving a plurality was given more than two thirds of the seats. Since parties representing national groups and regions were forbidden, the government's Yugoslav National Party, with police assistance, won all the seats in the assembly in 1931.

The civil liberties of all the national groups, including the Serbs, were deeply infringed by these actions. Many party leaders were sent to jail, including Vladko Maček, the new head of the Croatian Peasant Party; others went into exile. Especially significant for the future was the activity of Ante Pavelić. In January 1929 this Croat went to Italy, where, with the support of the Italian Fascist leader Benito Mussolini, he founded the Ustaša (Insurgent) movement. It

advocated the achievement of Croatian independence—if necessary, by violent means. The organization cooperated with the Internal Macedonian Revolutionary Organization (IMRO), which aimed at ending Serbian domination in Macedonia. In October 1934 a Macedonian assassinated Alexander and the French foreign minister, Louis Barthou, in Marseille. This action had great consequences for Yugoslav foreign and domestic policies.

The Regency: 1934-1941. Because Alexander's son, Peter II, was only 11 years old, a three-man regency, headed by Prince Paul, was established. Paul not only faced continuing internal controversies but also a worsening general European situation and a weakening of Yugoslavia's system of alliances. In 1920 and 1921, defensive alliances had been concluded with Czechoslovakia and Romania. The three states together formed the Little Entente, which was aimed at those neighboring countries that had lost territory to them in the peace settlements after World War I. The Little Entente developed in close association with France, with which Yugoslavia signed a treaty of friendship in November 1927. But French diplomatic hegemony in eastern Europe was soon challenged by Italy's Mussolini. Dissatisfied with the Italian world position, Mussolini set in motion plans to organize the states injured in the peace settlements—namely, Austria, Hungary, Bulgaria, and Albania, all Yugoslavia's neighbors.

After June 1935, when Milan Stojadinović became premier, Yugoslav foreign policy began to shift. Although Prince Paul was personally inclined to the West, he recognized that, given his uneasy domestic situation, he would have to come to an agreement with his restless neighbors. In January 1937 a treaty of friendship was signed with Bulgaria, and in March a nonaggression and arbitration pact was concluded with Italy. These understandings broke the letter and the spirit of the agreements with France and the Little Entente states. Yugoslav foreign policy was also profoundly affected by the German absorption of Austria in March 1938, an action that gave Yugoslavia a militant new neighbor, and by the dissolution of Czechoslovakia in March 1939.

The Stojadinović government also tried a new direction in domestic policy. Some civil rights were restored, and many political prisoners were released. The premier based his government on a new official party, the Yugoslav Radical Union, which was composed of the Serbian Radical Party, the Bosnian Muslims, and the Slovene People's Party. Although attempts were made to conciliate the Croats, very little was done to modify the Serbian-dominated centralist nature of the regime.

In December 1938 elections were held that marked what was in fact a defeat for the government. Despite police interference the opposition parties, which included not only the Croatian Peasant Party but also others that wanted a better national representation or more political rights, gained 44.9% of the votes to the government's 54.1%. The increasing tensions in international affairs, combined with the internal situation, made a radical change necessary. In February 1939, Stojadinović was dismissed.

The new premier, Dragiša Cvetković, a member of the Serbian Radical Party, was expressly instructed to come to an understanding with the

Croatian Peasant Party. With Prince Paul closely involved, government representatives carried on negotiations with the Croatian party's leader, Vladko Maček. Shortly before the outbreak of World War II, the discussions came to a successful conclusion with the signing of the Sporazum Agreement of August 1939. In this document Croatia received the autonomous position that its leaders had consistently demanded. Included in the lands under Croatian control were Dalmatia, Croatia, Slavonia, and some Bosnian and Hercegovinian territory with a Croatian population. Of the 4.4 million inhabitants, however, 866,000 were Serbs.

Croatia was now to have its own assembly; the chief executive official, the *ban*, was to be appointed by the king. In such matters as defense, foreign affairs, and communications, Croatia continued to be associated with the rest of the country. Ivan Subašić became the *ban*, Maček was appointed vice premier of Yugoslavia, and four members of his party received ministerial posts. This settlement, while meeting the major Croatian desires, caused resentment among the Serbs and demands from other national groups for similar concessions.

The Axis Conquest. Although an advance had been made toward easing domestic tensions, the international situation became increasingly dangerous. In April 1939, Italy occupied Albania. Germany's signing of a pact with the Soviet Union in August 1939, followed in September by the invasion of Poland and the declaration of war by France and Britain, inaugurated another long period of continental warfare. The defeat of France in June 1940, just after Italy entered the war, appeared to assure Axis domination of Europe. However, in October 1940, when Italy tried to invade Greece from Albania, the Italians were stopped by the Greek Army.

Although the German government had previously conceded to Italy the principal influence in Yugoslavia, a new situation developed that necessitated more direct German involvement. Since Germany was preparing to invade the Soviet Union and to assist Italy against Greece, the German leaders wished Yugoslavia to sign the Axis Tripartite Pact as an assurance of its benevolent attitude. On March 25, Cvetković and the foreign minister, Aleksandar Cincar-Marković, duly signed the document.

In protest, on the night of March 27, a group of officers carried out a successful coup. Gen. Dušan Simović became premier; Peter was declared of age, and Prince Paul resigned. Although the new regime did not denounce the Tripartite Pact, Hitler could take no chances in the Balkans. On April 6, Germany and Italy invaded Yugoslavia. They were aided by Hungarian troops, who entered Vojvodina; Bulgarian soldiers eventually occupied Macedonia. The war lasted only a short time, for an armistice was signed in Belgrade on April 17. The king and his ministers formed a government-in-exile in London. On June 22, Germany invaded the Soviet Union.

7. The Rise and Ascendancy of Tito

With German, Italian, Albanian, Bulgarian, and Hungarian troops in occupation and with puppet regimes in control in Belgrade, Zagreb, and Cetina, resistance movements soon gained strength. The first to win attention was the "Croatian" detachment of the Yugoslav Army,

formed by Col. Draža Mihailović and a group of Serbian officers after the surrender. The Chetniks, closely associated with the government-in-exile and King Peter, supported an eventual return to the Serbian-dominated centralist regime and the prewar social and political structure. The second resistance force, the Partisans, was led by the Communist Party and its head, Tito (Josip Broz), although it attempted to attract to its ranks all the national groups and the parties that opposed the occupation. The Partisans were particularly successful in their operations in the remote mountain areas, where tactics of guerrilla warfare could be successfully employed. The two resistance armies, representing opposite political orientations, soon came into open conflict. By the end of 1943 the Allies, judging that Tito was fighting more effectively against the enemy, decided to provide the major aid to the Partisans.

Whenever the Partisans gained control of a region, they also set up an administration. In November 1942, at a conference held in Bihać, the leadership established a central body called the Anti-Fascist Council for the National Liberation of Yugoslavia (AVNOJ). In November 1943 at Jajce, AVNOJ was declared to be the government of Yugoslavia, in effect repudiating the government-in-exile. Britain, desiring to bring the two together, arranged for a meeting on the island of Vis in June 1944 between Ivan Subašić, the premier of the London regime, and Tito. Here it was agreed that AVNOJ would be the recognized political authority, but that members of the London government should join it. Subašić was to be postwar foreign minister.

Once the fighting had ceased, the victors proceeded with the partition of Yugoslavia. Germany annexed part of Slovenia and took control of the Banat, which had a large German population. Italy gained the rest of Slovenia and most of Dalmatia. Albania, now an Italian puppet state, was given the Kosovo area and some Montenegrin and Macedonian land. Hungary received Bačka and Baranja. Bulgaria, having occupied Macedonia, hoped that it would keep that area. The rest of the country was returned to its historic divisions. Serbia, assigned the boundaries it had had before the Balkan Wars of 1912-1913, was controlled by Germany with a government under Gen. Milan Nedić. Italy established a puppet government in Montenegro.

The most controversial political events, however, occurred in Croatia, which was placed under the control of Ante Pavelić and his Ustaša forces. In theory an independent state, Croatia was assigned Bosnia-Hercegovina as well as the historic lands of Croatia and Slavonia, and, after the surrender of Italy in 1943, Dalmatia. These territories contained a population of 6.5 million, of which only 3.4 million were Croats. The Ustaša regime organized a campaign of forced conversion or annihilation of the Serbian Orthodox. A condition of chaos and internal civil war soon developed, with open conflict between the Serbs and Croats resulting in high casualties.

On Oct. 20, 1944, Partisan and Soviet forces took Belgrade. As the fighting came to an end, the Partisans were in military control of the country. Tito then moved to crush any remaining resistance. When the representatives of the London government attempted to assume office they found their position untenable. The prewar Yugoslav parties were prevented from carrying

on political activities. Major parties therefore refused to participate in the elections held in November 1945 for a constitutional assembly, and the voters had only the official Popular Front list before them. In a highly controlled election, 90% of the voters endorsed the government candidates. In 1946, Mihailović was captured and executed.

Tito in Power. In November 1945 the constitutional assembly abolished the monarchy and proclaimed the Federal People's Republic of Yugoslavia. Once firmly established, the government introduced Communist political and economic institutions. In 1963 the official name of the country was changed to the Socialist Federal Republic of Yugoslavia.

In the immediate postwar years, relations with the Soviet Union were good. A treaty of friendship and cooperation had been signed in April 1945. In contrast, conflict with the Western powers, particularly the United States, arose over ideological issues, the downing of two American aircraft in Yugoslavia, and Tito's dissatisfaction with the boundary settlement with Italy, in particular the failure to gain Trieste, which became a free territory. Yugoslavia did, however, win from Italy most of the rest of Istria, the city of Zadar (Zara), and Dalmatian islands.

By 1948, Tito's attempt to follow an independent foreign policy brought him into conflict with Stalin. In March 1948, Soviet military and civilian advisers were recalled. On June 28 the Cominform, the Soviet-dominated organization of Eastern European states, expelled Yugoslavia.

Finding itself isolated and in need of economic assistance, Yugoslavia then turned toward the Western powers. Despite their anti-Communist stance, the United States and other Western governments gave Tito both economic and military assistance. Relations were improved with neighboring non-Communist Greece, Italy, and Turkey. In 1954, Yugoslavia and Italy signed an agreement finally settling their boundaries. By its terms the Free Territory of Trieste was divided, with Italy receiving the city and a seacoast connection to it but with Yugoslavia taking the major portion of the territory.

After the death of Stalin in March 1953, diplomatic relations with the Soviet Union and the Communist bloc gradually improved. In May 1955, Nikita Khrushchev and other Soviet leaders came to Yugoslavia; in June 1956, Tito returned the visit. Yugoslavia did not, however, rejoin the Communist alignment. Instead Tito attempted to establish a third camp of neutral, or nonaligned, nations. In this endeavor he cooperated with other leaders of newly independent states or of those states that had refused to join either of the Great Power blocs. Relations with the Soviet Union cooled after the Soviet invasion of Hungary in 1956 and especially after the occupation of Czechoslovakia in 1968. Although a visit by Soviet leader Leonid Brezhnev in 1971 marked an improvement in the atmosphere, Tito maintained his independent attitude until his death.

The Collective Presidency. The constitution of 1974 called for a collective presidency consisting of a president and one representative from each of the six republics and the two autonomous provinces. The members of the presidency were elected for a period of five years by the Assembly

Tito (Josip Broz; at right) with members of his staff at Partisan headquarters during World War II.

of the Socialist Federal Republic of Yugoslavia (SFRY), the highest body of the government. In 1974, Tito was made president of the country for life, and by virtue of this position, he became president of the collective presidency. The office of vice president rotated on an annual basis among members of the collective presidency.

When Tito died in May 1980, the vice president for that year succeeded him as president of the collective presidency. When the new president's annual term ended, the next in line under the system of rotation replaced him as the president for the succeeding year. Afterward the system of rotation continued to function as intended.

8. Yugoslavia After Tito

Marshal Tito had stage-managed his succession in the form of an elaborate power-sharing arrangement that replaced his own charismatic authority. Post-Tito politicians rotated rapidly in the collective leaderships of the Communist party and the state. Within the party—officially the League of Communists of Yugoslavia (LCY)—were ten key political organizations: the federal party, the eight regional parties, and the party organization of the Yugoslav armed forces. Most federal political jobs, including those in the foreign ministry and the diplomatic corps, were apportioned on the bases of regional identity (the home republic or autonomous province) and ethnic identity within the region (reflecting the Muslim, Serb, and Croat composition of Bosnia-Herzegovina). A consensus of the six republics and two provinces served as the standard basis of decision making. This complex quota system had a logical continuity with the fundamentals of Yugoslav self-management: democratization, decentralization, debureaucratization (less bureaucracy), and deprofessionalism (bringing citizens into the political process through self-managing institutions in local government, such as "people's councils" and numerous commissions).

© THE BETTMANN ARCHIVE

Marshal Tito, who became president of Yugoslavia for life in 1974, lies in state after his death in 1980.

In view of the affection for Tito and insecurity over his passing, power sharing was legitimized by its being Tito's own political legacy. Yet in the context of an already highly decentralized federalism, in which the federal government retained control over only foreign policy, national defense, and an ambiguously defined "united market," the linking of political position to regional and ethnic identity undermined national integration and therefore national unity. The dizzying speed of political rotation limited opportunities to build a name with public recognition. And decision making by consensus gave the leaders of the republics and autonomous provinces what amounted to veto power.

The difficulties of Tito's successors were exacerbated by the country's Western debt, which was estimated at \$20 billion in 1980. Politically the new leaders needed the afterglow of the Tito personality cult. Their legitimacy was a corollary of their commitment to "guarding Tito's way." At the same time, they were uncomfortably saddled with blame for his economic mismanagement. By 1983 the Krajger Commission on Economic Stabilization had recommended a long-range program to repair the economy under the supervision of the International Monetary Fund (IMF).

It soon became apparent, however, that the government did not have the power to push these measures through without the cooperation

of the regional politicians. But, as with the campaign for market socialism in the 1960s, the political leaders of the republics and provinces could not agree on the distribution of the benefits and burdens of reform.

Throughout the 1980s the Yugoslav economy reeled under the burden of debt servicing. The IMF and Western financial circles would re-schedule debts only at the price of imposing another painful austerity program. Unemployment rose. Inflation galloped forward, topping 2,000% in 1989, while the standard of living for ordinary Yugoslavs declined. Notwithstanding the commitment to the nonaligned movement, symbolized by hosting the movement's 1989 summit in Belgrade, the imperatives of debt servicing and of relating to the 1992 economic integration of the European Community (EC) dominated post-Tito foreign policy.

While Tito's memory dwarfed his successors, the economic crisis that he left them ruled out economic performance as a source of their legitimacy. Yet their perceived right to govern depended on their delivering on the promises of a smoothly functioning welfare state in which the standard of living improved steadily. The post-Tito "parcelization" of power slowed the ability of the government to act. When Premier Branko Mikulić resigned in December 1988, he insisted that blame for the economic crisis went far beyond the federal center, for regional Communist politicians were infected with economic as well as political nationalism.

The populist tactics of Serbian strongman Slobadan Milošević succeeded in partially reintegrating the autonomous provinces of Kosovo and Vojvodina into Serbia, at the cost of strikes, riots, and deepening distrust among Kosovar Albanians. Criticism by Slovenes of what they saw as Serbian ambitions to gain hegemony in Yugoslavia widened the circle of conflict. Slovenes rewrote their constitution to claim sovereignty explicitly and reiterated their federal right of secession. The escalating polemics, which soon expanded to Croatia, contributed to 1990 election victories of the united Slovene opposition (DEMOS) and the Croatian Democratic Union (CDU). Political parties proliferated in Serbia as well.

The LCY, which had given up its monopoly of power in January 1990, withered away. Asserting that Yugoslavia would function with or without the LCY, Premier Ante Marković set up his own Alliance of Reform Forces in support of the government's agenda. His anti-inflation program had slowed price increases to a crawl; and he had already reduced the Western debt to roughly \$16 billion, while cutting back the ratio of foreign currency tied up in debt servicing from 45% to 16%. More important, Marković had created the legal infrastructure needed to move forward on economic reform.

By midsummer, Yugoslav economic reforms had far outstripped the Polish road to capitalism. Politically, however, Marković's reform party was no match for Serbian president Milošević's Socialist Party of Serbia (former Communists) or nationalist parties in Bosnia-Herzegovina and Macedonia. As 1990 ended, multiparty elections in the six republics had brought to power center-right coalition governments in Slovenia and Croatia, nationalist-dominated coalitions in Bosnia-Herzegovina and Macedonia, Milošević's renamed Communists in Serbia, and the Con

munist Party of Montenegro. Divided over the federal or confederative nature of the country's future political system, these republic politicians could not agree on procedures for conducting the promised federal elections.

In the meantime, new players joined in the struggle between the imperatives of economic reform and national self-determination. By changing the Croatian constitution, Franjo Tudjman's CDU responded to pressure by Croatian voters to deal with what many Croats had come to feel was second-class citizenship in their own republic. Memories of World War II atrocities intensified fears of the roughly 600,000 Serbs in Croatia (about 12% of the republic population). There were violent incidents, a referendum demanding Serbian autonomy in Croatia, and appeals to Serbia and the Yugoslav army for protection. The Croatian government refused to recognize the self-proclaimed Serbian autonomous region of Krajina, established a republic militia to deal with "criminals" barricading the main road to the Dalmatian coast, and blamed Serbian President Milošević for manipulating the fears of the Serbian minority. Serbs, in turn, were more and more convinced that Tudjman's government was intent on subjugating Croatia's Serbian minority.

Ethnic tensions escalated following a financial scandal brought about by the Serbian parliament's decision to issue \$1.8 billion in new money without informing the federal govern-

ment. Faced with a World Bank warning that credit to Yugoslavia would be cut off if the premier's market-based reform program was abandoned, Serbia agreed to some restitution, but its economic credibility never recovered. Milošević's reputation suffered at home and abroad. By March 1991 massive demonstrations against the Serbian president's heavy-handed political tactics as well as his economic mismanagement appeared to have weakened his control within Serbia itself.

In an abrupt role reversal, Borisav Jović, the Serbian president of the state presidency, resigned. Milošević refused to recognize the authority of the federal presidency, while the "sovereign" republics of Slovenia and Croatia came to the defense of Yugoslav unity with calls for a meeting to preserve the federation. The European parliament reiterated its concern for Yugoslav integrity, pledging a \$1.1 billion loan and promising to open negotiations on associate membership for Yugoslavia to the European Community.

This window of opportunity slammed shut, though, with a subsequent Serbian-Montenegrin move to block Stipe Mesić, a Croatian, from rotating into the office of president of the presidency on schedule. Slovenia and Croatia declared "independence" at the end of June. Shooting began when the Yugoslav army tried to reestablish the federal customs presence on Slovenia's international borders. Although an EC-brokered cease-fire monitored by Community observers in Slovenia held, by August the violence rapidly escalated in the Krajina region of Croatia. Local Serbian authorities, who had served warning that they would not live in a Croatia outside of Yugoslavia, declared that they were uniting with Bosanska Krajina in Bosnia-Herzegovina to form a "greater Serbian community."

Political dialogue among republic leaders now collapsed into polarized confrontation. The Serbian agenda shifted to that of a rump Yugoslavia minus Slovenia and Croatia. Hardliners within the Yugoslav armed forces more and more openly supported Serbian irregulars battling Croatian militia in what appeared to be a Serbian land grab. Macedonia stated that it was unwilling to coexist in any such greater Serbia and declared its own "independence"; Bosnia-Herzegovina soon did so as well. The Croatian leadership desperately attempted to "provoke" Germany into following through on its threat to recognize Croatia if Serbian insurgents and their supporters did not stop fighting. Slovenia struggled to consolidate the gains of early summer. As Germany, Italy, Austria, and Hungary recognized Croatian and Slovene passports, Yugoslavia ceased de facto to exist.

YUKAWA HIDEKI, yōō-kā-wā hē-de-kē (1907–1981), Japanese physicist, who won the 1949 Nobel Prize in physics for his work on mesons. He was born in Tokyo on Jan. 23, 1907, and graduated from the University of Kyoto in 1929. Attracted to theoretical atomic physics, he did intensive work from 1929 to 1935 on the theory of elementary particles. During those years the picture of the atom was undergoing radical and rapid change. In 1911, Ernest Rutherford had proposed a model of the atom which closely resembled the solar system, with electrons orbiting about a central, positively charged nucleus. The study of radioactive substances had shown that the nucleus itself was a highly structured body containing alpha and beta particles. The discovery of the neutron by James Chadwick in 1932 added another nucleon whose presence in the nucleus had to be accounted for by theory. It was becoming increasingly clear that the simple gravitational and electromagnetic forces of macrophysics were not sufficient to explain how nucleons were bound together into a stable body. Attempts were made to reduce nuclear forces to the forces associated with the known nuclear particles, but the calculated values were always much too small.

To fill this gap, Yukawa introduced the idea of the meson field and in 1935 predicted the existence of still another particle, the meson. In 1937 particles intermediate in mass between the electron and proton were discovered in cosmic rays. This discovery confirmed Yukawa's prediction and gave great impetus to the development of nuclear theory. Yukawa received the 1949 Nobel Prize in physics for this work.

In 1939, Yukawa became professor of theoretical physics at the University of Kyoto. He was visiting professor at Columbia University in 1949–1953 and then returned to Japan as director of the Research Institute for Fundamental Physics at Kyoto from 1953 to 1970. He died in Kyoto on Sept. 8, 1981.

YUKON RIVER, yōō'kon, one of the longest rivers in North America. It is located mainly in Yukon Territory, Canada, and the U.S. state of Alaska. The river drains an area of about 360,000 square miles (930,000 sq km), of which some 127,000 square miles (330,000 sq km) are in Canada. The Yukon rises from one of its principal sources only 15 miles (24 km) from the Pacific Ocean in northern British Columbia. It pursues a tortuous route of over 1,900 miles (3,057 km), generally north and west, before terminating in Norton Sound, an arm of the Bering Sea, on the west coast of Alaska. Its course through Alaska extends 1,265 miles (2,035 km).

Small steamships formerly operated along the upper Yukon (then known in this sector as the Lewes River) for a distance of 100 miles (160 km) between Bennett Lake, on the British Columbia-Yukon Territory border, and the dangerous waters of Miles Canyon and Whitehorse Rapids in Yukon Territory. Below these impediments large sternwheeler steamships and tugboats once plied the river's waters during a five-month navigational season from the city of Whitehorse all the way to the sea, 1,777 miles (2,860 km) downstream. From Whitehorse the river continues northward in Yukon Territory through Lake Laberge to a junction with the Teslin River, then

with the Big Salmon River and the Pelly River, its principal tributary in Canada. From there the Yukon flows northwest with many windings, being joined in succession by the White, Stewart, and Sixtymile rivers, and (at Dawson) by the Klondike, a river celebrated for the gold rush in the years after 1896 (see KLONDIKE). After receiving the Fortymile River, locale of another gold discovery, the Yukon enters Alaska, maintaining its northwesterly route as far as Fort Yukon on the Arctic Circle, where the river is joined by the Porcupine from the northeast. Thereafter the Yukon follows a southwesterly course across Alaska to its mouth, the chief tributaries being the Tanana and Koyukuk rivers.

In its lengthy course the Yukon passes through many sorts of terrain. Its headwaters in the Stikine, St. Elias, and Coast mountains are characterized by scenic valleys, rocky gorges, and long, finger-shaped lakes. Below Whitehorse the Yukon system has worn deeply terraced valleys as it flows through the elevated Yukon Plateau. After entering Alaska the river meanders in innumerable channels through the Yukon Flats, a region of shifting sandbars and low wooded islands. Below the mouth of the Tanana the Yukon becomes a huge, muddy stream flowing through a broad spruce-covered plain and finally terminates in a marshy delta.

From 1866, when the first small steamer ascended the Yukon, the river became the principal means of transportation and communication for interior Alaska and the Yukon Territory, and traffic attained considerable volume following the discovery of gold in the Klondike region. Railways, roads, and air services have displaced the river, and only private vessels and tour boats still use the mighty waterway. Proposals to develop the enormous hydroelectric potential of the Yukon system include reversing some of its headwaters to flow directly to the Pacific Ocean by way of the Taku River, or damming the main river at the Ramparts, 100 miles (160 km) northwest of Fairbanks, Alaska. But except for a small hydroelectric plant above Whitehorse, the Yukon remains unharnessed and little traveled, flowing in almost primitive solitude, alongside or through national wildlife ranges for most of its length in Alaska.

Kaskaulsh Glacier in the Yukon's St. Elias Mountains, in which rise Canada's seven highest peaks.

YUKON TERRITORY, yōō'kon, a region of Canada, established as a separate territory in 1898. It was named for the Yukon River, called *Yu-kun-ah* ("great river") by the Indians. Comprising the wedge-shaped northwestern part of the Canadian mainland, the Yukon is bounded on the north by the Beaufort Sea, on the east by the Northwest Territories, on the south by British Columbia, and on the southwest and west by the state of Alaska. With an area of 186,300 square miles (482,515 sq km), equal to 4.9% of Canada's total, but with a population of only 23,153 (1981 census), the Yukon is one of the most sparsely settled regions of the world. Whitehorse is the capital and largest city (population, 14,814).

The Yukon probably still is best known for the Klondike gold rush in the late 19th century, an event whose drama and romance is celebrated in the short stories of Jack London and the poems of Robert Service. Nowadays, the gold rush is remembered by two major celebrations: Discovery Day, in Dawson on August 17, commemorating the great Klondike gold strike of 1896, and the Sourdough Rendezvous, in Whitehorse in February, honoring the prospectors, called "sourdoughs," who braved the wilderness in search of riches. See **KLONDIKE**.

The Land. Mountain chains stretch across the Yukon in a northwesterly direction. The lofty, scenic, icefield-encrusted St. Elias Mountains in the southwest include Canada's seven highest peaks, headed by Mt. Logan at 19,524 feet (5,951 meters). Northern extensions of the Rocky Mountain chain form part of the eastern border, then swing west across the Yukon in the Ogilvie Mountains.

Most of the territory is rugged, rolling, elevated plateau, intersected by precipitous rivers that have incised deep valleys. They include the headwaters of the eastward-flowing Liard River and the numerous tributaries of the mighty Yukon River, notably the Teslin, Pelly, Stewart, and White rivers. In the north are the basins of the Peel and Porcupine rivers and the Richardson and British mountains.

Climate. The Yukon's climate is extreme northern because of its Arctic-subarctic location and high elevation, and because the Coast Ranges bar mild Pacific winds from the territory. Winters are long and severe, with January tem-

peratures averaging -18°F (-28°C), while summers are short, with about three months (June–August) between the last and first freezing temperatures. The lengthened summer days quickly bring forth a rich profusion of colorful wildflowers, including the fireweed (*Epilobium angustifolium*), the floral emblem of the Yukon. Annual precipitation is in the range of 9–13 inches (230–330 mm), comparable with the most arid parts of Canada's prairie provinces.

The climate and elevation slow the growth of the Yukon's forests. Also, these factors, as well as limited suitable soil areas, sharply reduce opportunities for successful farming.

Dawson, the thriving center of the Klondike gold rush, is now a quiet village on the banks of the Yukon River.

Resources and Economy. Only two of the Yukon's natural resources—fur and minerals—have given rise to industries that direct their products to export markets. Timber finds local uses as fuel and building material but is not yet a commodity of external trade. Hydroelectric power, which has enormous potential in the Liard and Yukon river basins, has been developed only to meet local needs. Similarly, the produce of the territory's few small farms and ranches is consumed locally.

Wildlife. Fur-bearing animals, including muskrat, lynx, mink, marten, and beaver, provided the source of the Yukon's first and longest-lasting export industry—the fur trade. Game animals, such as mountain sheep and goats, caribou and moose, and grizzly and black bears, furnish food and skins for the population and attract visiting hunters. Among other edible wildlife are hares, ducks and geese, and salmon and other kinds of fish.

Minerals. Gold mining was the Yukon's leading industry until the 1950's. The large Klondike operation closed in 1966, but small operators, encouraged by the high price of gold since 1970, continue to mine with bulldozing equipment at many creeks. Between 1920 and the 1970's there was a major silver-lead operation in the Mayo district. Three new mining operations went into production in the mid-1960's—a large lead-zinc mine at Faro in the Ross River section, a copper mine near Whitehorse, and an asbestos mine at Clinton Creek near Dawson. Small tonnages of low-quality coal also have been mined at Carmacks for local customers. Prospecting for gas and oil began in the 1950's, but there have been no major finds.

While mineral resources can provide relatively high-income employment, such employment is uncertain because of ore exhaustion or of closings resulting from unfavorable markets. "Boom and bust" characterizes the Yukon's mining-based economy, with growth in certain periods, as during the Klondike gold rush and the 1960's, and decline in others, such as 1982–1983, when the territory's metal mines were closed, with great damage to the economy.

Tourism. In the Yukon, tourism is a major source of revenue, with about 325,000 visitors each year. The territory's scenic beauty, dramatic history, and contiguity with Alaska have drawn tourists since the early 20th century. Early visitors traveled to Whitehorse from Skagway, Alaska, by train and on to Dawson and farther up the Yukon River by steamer. Today visitors arrive by air or by automobile and tour the Yukon and Alaska by road. Government aid to tourism includes advertising campaigns, incentives to improve facilities, and historical reconstructions, particularly at Dawson.

Transportation and Communications. The Yukon River and its major tributaries furnished the principal means of transportation until World War II. In response to the Klondike gold rush, the narrow-gauge, 110-mile (177 km) White Pass and Yukon Railway was built to connect Whitehorse with Skagway as an opening to the Pacific. Also in the wake of the gold rush, telegraphic communication was established between Dawson and Ashcroft, British Columbia. Wireless communication has replaced the largely unserviceable 1,200-mile (1,900-km) telegraph line, and the railway has faced hard times, especially since 1982.

During World War II the United States built the graveled Alaska Highway from Dawson Creek, British Columbia, to Fairbanks, Alaska, passing through the southern Yukon; a 160-mile (265-km) road from the highway in the Yukon to the seaport of Haines, Alaska; a Canol Road southwestward from the Northwest Territories to the Alaska Highway; and an oil refinery at Whitehorse and oil pipelines along most of the roads. Also, airfields at Watson Lake and Whitehorse were improved. After the war the refinery and most pipelines were removed, and the Canol Road was abandoned. However, the other facilities remained, and additional roads and airfields have been built.

The Yukon's roads total about 2,775 miles (4,465 km). Modern highways have been constructed from Whitehorse to Dawson; from the Alaska Highway to the mining centers of Faro in the Yukon and Tungsten in the Northwest Terri-

tories; and from Dawson to Fort McPherson and Inuvik in the Northwest Territories—the Dempster Highway, which nearly reaches to the Beaufort Sea.

Whitehorse is served by major air services and is the main center for regional air carriers engaged in such activities as local transportation, surveying, and prospecting.

Radio and television service are provided by the Canadian Broadcasting Corporation and private stations, and Canadian National Telecommunications link the Yukon by telephone to the outside world.

Government. The Yukon Act, which established the territory in 1898, provided for a federally appointed commissioner and a territorial council to enact local ordinances that the federal cabinet could disallow. At first the council was comprised of federal officials, but by 1909 it consisted of 10 elected members. A small territorial civil service was set up to handle such local concerns as schools, roads, and municipal affairs.

Council membership was reduced to three in 1919 because of a sharp decrease in population, but after activity quickened during World War II, membership was increased, reaching 16 in 1978. In 1961 the council received greater responsibility when three members began serving on a financial advisory committee. In 1970 two councillors (three, beginning in 1974) were appointed to an executive committee to participate with the commissioner and deputy commissioner in departmental administration. Since 1978 the council, renamed the legislative assembly in 1974, functions along party lines, under a government leader and a five-member cabinet drawn from the majority party. The commissioner approves all legislation and is responsible to the federal government.

The assembly has endeavored to gain control of certain fields under federal jurisdiction and aims toward eventual provincial status. The federal government has been unresponsive, contending that the territory's small population and reliance on federal financial aid argue against full self-government and provincial control of the region's natural wealth.

Since 1902 the Yukon has been represented in the House of Commons by one member. Fol-

lowing many years of direct management by the territorial government certain population centers now have elective municipal offices. A judge presides over the territorial supreme court, and 32 appointed justices of the peace handle local judicial matters. The Royal Canadian Mounted Police serve under contract as the police force.

Social Services and Education. Yukoners receive about the same aids and services as other Canadians. These include family allowances and pensions; free hospitalization and medical service under the national health program; facilities for senior citizens and other special groups; unemployment insurance and workmen's compensation; loans for public utilities and housing; and subsidized housing for low-income families.

Enrollment in the territory's some two dozen schools, including Roman Catholic schools in Whitehorse, is about 5,000. The system includes kindergartens and elementary and secondary schools, all of which follow the curriculum of British Columbia; a technical and vocational training institute; and adult-education programs. A Yukon college has been established to administer all postsecondary programs, but for a university education students still must travel outside the territory.

History. Since the Yukon Territory lies athwart the migration path from Asia to the Americas, human occupation of the area may have begun as early as 30,000 years ago. In historical time the Yukon was inhabited by nomadic hunting and fishing Athapaskan Indian peoples—in the north, in the Yukon River basin, and in the mountainous southeast. Tlingit Indians from the Pacific coast lived in the southwest. A small Inuit (Eskimo) population was found in the Arctic region.

Fur traders of the Hudson's Bay Company were the earliest white men to explore the present Yukon Territory. In 1840, Robert Campbell reached the Pelly River, which he descended in 1843 to its mouth in the Lewes River, as he called the upper Yukon. There he built Fort Selkirk in 1848. In 1851, Campbell followed the Lewes downstream, arriving at Fort Yukon in Alaska, thus discovering that the Lewes was the upriver extension of the Yukon. The entire river was named the Yukon in 1949.

LIBRARY OF CONGRESS

A Klondike merchant used a tent to serve his customers during the gold rush in the 1890's. Thousands of prospectors, called sourdoughs, braved the discomforts of the Yukon wilderness in search of riches.

The Hudson's Bay Company found the upper Yukon region too difficult to supply for extensive trade and soon abandoned the area. However, an increasing number of free traders and gold seekers moved in from Alaska via the Yukon River. Beginning in the early 1880's travelers also made their way to the Yukon from newly established ports on Lynn Canal in Alaska, climbing the steep passes of the coastal mountains to reach the navigable headwaters of the Yukon River. In 1894 changing conditions in the Yukon prompted the Canadian government to send a North-West Mounted Police officer to study the situation. The next year a detachment of police was moved there to keep order and to represent federal departments, and the Yukon became a district of the Northwest Territories.

In mid-August 1896, George W. Carmack and two Indian companions made a stunning gold strike on Bonanza Creek, a tributary of the Klondike River. The gold rush that followed brought world fame to the Yukon and was the highlight of its history.

Shortly after the find thousands of people headed for the goldfield. Steamboats plied the Yukon River, and the White Pass and Yukon Railway was completed in 1900. Near the confluence of the Yukon and Klondike rivers, the city of Dawson was built. It became a thriving frontier town, known as the Paris of the North, with a population that reached 25,000 in 1898. That year the Yukon was created a separate territory, with its capital at Dawson.

The Yukon appeared to be on the verge of a brilliant future, as the gold rush reached its peak in 1898-1899. But the richest placers were being worked out, few new discoveries were made, and other industries failed to develop. The gold operation was taken over by large companies able to work leaner gravels profitably by introducing cost-cutting methods, such as the use of hydroelectric power, high-pressure hoses, and huge dredges. Although gold production increased for a time, profits went to outside investors, rather than to developing the Yukon, and the territory slipped into a prolonged decline. In 1931 the census recorded 4,230 Yukoners, down from 27,219 in 1901. Once-booming Dawson, which lost its capital status to Whitehorse in 1953, had only 819 inhabitants.

During World War II, mainly as a result of construction of the Alaska Highway and oil pipelines, the Yukon saw another large influx of people, up to 35,000 military personnel and civilians in 1942-1943. Following the war, the population declined, to 9,096 in the 1951 census. Since then, however, with the expansion of economic activity and government employment, the population has increased fairly consistently among both whites and native inhabitants. Aided by such factors as improved health services and greater economic opportunities, the native residents number about 7,000, or nearly 30% of the Yukon's people.

YUMA, yōō'mə, a city in Arizona, the seat of Yuma county. Situated on the Colorado River, in the extreme southwest part of the state, Yuma is 160 miles (258 km) southwest of Phoenix. It derives its name from the Yuma Indians, whose reservation is nearby. Yuma is an important agricultural center in an area of irrigated farms producing lettuce, citrus fruits, dates, melons, and alfalfa. Also important to the economy are extensive livestock-feeding operations, tourism, and light manufacturing. The Yuma Test Station, a major hot-weather testing point for Army matériel, is 28 miles (47 km) north of the city, and a Marine Corps air station is on the outskirts.

Places of interest include the Yuma Territorial Prison State Park, a museum housing many relics of Yuma's lively history; the Century House Museum, with exhibits from Arizona's territorial period; the Custom House, a military supply center in the 1870's; and St. Thomas Mission, an adobe structure on the reservation Martinez Lake, on the Colorado River, 35 miles (56 km) north of Yuma, provides recreational facilities, and a rodeo is held each February.

Hernando de Alarcón, who sailed up the Colorado River in 1540, probably was the first white explorer of the region. Father Francisco Garcé established a mission in 1779, but it was abandoned in 1781 when he was killed by Indians. The town of Colorado City sprang up in 1854 at the ferry crossing of the Colorado River, after the discovery of gold in California. Its name was changed to Arizona City in 1858. In 1862 this settlement was destroyed by a flood, and a new community was formed on higher ground. It was renamed Yuma and incorporated in 1873. Yuma has a council-manager form of government. Population: 42,433.

MILDRED C. LUDECKI
Librarian, Yuma City County Library

YUMA INDIANS, yōō'mə, one of the major tribes of the Yuman branch of the Hokan linguistic stock. They originally lived on both sides of the lower Colorado River, around the site of the present city of Yuma, Ariz. Encountered by Hernando de Alarcón in 1540, they were first mentioned by name by Eusebio Francisco Kino in 1702 and were in frequent contact with subsequent explorers and travelers. The meaning of the name is unknown; it may be an error in understanding *yamayo*, "a chief's son." The people call themselves Kuchiana; current usage substitutes Quechan as the name for this tribe.

The traditional culture of the Yuma is similar to that of their congeners, the Mojave. They believed in a creator, Kwikumut, who made all things. Religious customs included a strong belief in dreams and great annual public mourning ceremonies. The tribe was divided into settlements of several hundred people each. Food was gathered and cultivated, and hunting was minimal. The Yuma were somewhat warlike and made effective use of a short "potato masher" club in hand-to-hand combat. The men often went naked, and the women wore short bark-cloth aprons, decorating their bodies with paint. Yuma art was not highly developed; functional pottery and, occasionally, simply modeled clay effigy figures were made. The tribe lives on Fort Yuma Reservation in California, across the Colorado River from the city of Yuma.

Author of "Great North American Indians"

YUNG LO, yōng'lo, the era name ("Perpetual Happiness") of the third emperor of the Ming dynasty in China. His personal name was Chu Ti; his dynastic name, Ch'eng Tsu.

Chu Ti was born in Nanking on May 2, 1360. As prince of Yen, with a large personal following in the region of modern Peking, he forcibly took the Ming throne from a nephew in 1402. The Yung Lo (Yongle) emperor ruthlessly punished officials who had opposed his insurrection, centralized authority firmly in his own hands, and in 1421 transferred the capital to Peking, a newly rebuilt imperial city at the site of the Mongols' Khanbalik. He repeatedly campaigned in person against the resurgent Mongols to the north, incorporated Annam (northern Vietnam) into the Ming Empire, and from 1405 dispatched a series of great armadas, chiefly under the eunuch admiral Cheng Ho, to bring back tribute from as far away as Java, India, the Persian Gulf, and East Africa.

Under Yung Lo's imperial sponsorship, scholars completed the *Yung-lo ta-tien*, a monumental edition of extant literary, historical, and philosophical writings. The emperor died in August 1424 while returning from one of his expeditions into Mongolia.

University of Michigan

YÜNNAN, yün'nán', a province of southwestern China, bounded on the south by Vietnam and Laos and on the west by Burma. The province covers 152,000 square miles (394,000 sq km). A fourth of Yünnan's population is made up of some 30 non-Chinese nationality groups. They live for the most part in self-administered areas, chiefly in the west and south. Yünnan's total population was reported in the 1982 census as 32,553,817.

Kunming, the provincial capital, lies in the more densely settled eastern part of the province. It is Yünnan's chief industrial center and only large city, with a population (1980 est.) of 1,950,000. Three other cities have municipality status: Koku, a tin-mining center in the southeast, near the Vietnam border; Tungchwan, a copper-mining center in the northeast; and Siakwan, a regional transportation hub in the west, on the Yünnan-Burma Road, near Tali, a town famous for its marble quarries.

Physical Features. Yünnan can be divided into two distinct regions. The land east of the Red (Yüan) River is an integral part of the broad Yünnan-Kweichow Plateau. This eastern region contains many lakes. Elevations average 3,000 to 6,000 feet (900–1,800 meters) and are generally about 2,000 feet (600 meters) higher than the Kweichow portion of the plateau, which is farther east.

The mountainous western part of Yünnan is an extension of the Tibetan Highlands. It includes several parallel mountain chains that run generally from north to south, with elevations decreasing southward from 12,000 feet (3,650 meters) to 6,000 feet (1,800 meters). These mountain chains, collectively referred to as the Hengtwan Mountain Range, delimit the courses of major rivers that flow southward through sharply etched canyons. The Salween (Nu), Mekong (Lantsang), and Red rivers continue into Southeast Asia, but the Yangtze turns eastward and marks part Yünnan's northern border on its way through the center of China.

The name Yünnan means "south of the clouds," a reference to the Yünlíng Shan, or Cloudy Mountains, in the northwest. The province has a nearly uniform climate in the east, but temperatures vary markedly in the west, chiefly because of the sharp contrast of high mountains and steep canyons. The average temperature at Kunming ranges from 48° F (9° C) in January to 73° F (23° C) in July. At Tengchung, in western Yünnan, the January temperature averages 27° F (–3° C) as against 69° F (21° C) in July.

Agriculture and Forest Resources. On Yünnan's eastern plateau grains are grown on small upland plains, on terraced hillsides, and in river valleys. Rice, maize, millet, and barley are the major summer crops; wheat and oilseed are produced during the winter. Other important crops include sugarcane, which is grown in the Nanpan River valley of southeastern Yünnan, and sweet potatoes, which are planted throughout the eastern agricultural area. The province produces significant quantities of soybeans and lesser amounts of tobacco, fruits, and nuts. Puerh, a county in the southwestern corner of Yünnan, exports to other parts of China a highly regarded black tea.

Western Yünnan, where coniferous trees thrive in the acidic dark-gray soils, has extensive but largely unexploited timber stands. The inadequacy of that area's transportation facilities retards the growth of forest industries.

Mining. Yünnan is noted for its great variety of minerals, particularly nonferrous metals. Its tin deposits rank among the world's largest, and the output of the leading tin center, Koku, accounts for a major part of China's production of that metal. Modernized and expanded mining of copper, lead, and zinc takes place in the Hweishan area of the northeast. The copper mine at nearby Tungchwan has been important since the 17th century. Other significant mining production is carried on near Kunming: coal at Ippling to the west and iron at Imen to the south.

Yünnan also produces antimony, tungsten, mercury, phosphorus, manganese, silver, gold, phosphates, and salt.

Manufacturing. Modern manufacturing is concentrated in Kunming. The city has copper and iron smelters and factories that turn out steel, machine tools, trucks, mining and agricultural machinery, electrical equipment, precision instruments, chemicals, textiles, and foodstuffs. Dozens of hydroelectric power plants have been built in the vicinity.

Transportation. Prior to 1949 the only significant rail line in Yünnan was the single-track Kunming-Hokow section of the Yünnan-Indochina Railway. Thereafter, new rail lines were constructed to link Kunming with Kweichow province to the west and Szechwan province to the north. The capital is also the Chinese terminus of the Yünnan-Burma Road, built during World War II. The city's airport handles domestic and international flights.

History. Although the Yünnan area had been under nominal Chinese suzerainty since the advent of the Chinese Empire in 221 B.C., the area's remoteness and the loyalties of the peoples to their local leaders prevented the Chinese from exercising any effective control over the area until Ch'ing times (1644–1912 A.D.). With the rise of the Ming dynasty in 1368, military-supported Chinese colonization was encouraged in eastern Yünnan, but the territory was

still administered by local leaders who were responsible to the central government. This *t'u-su* system of indirect rule was formalized during the Ming dynasty, but the Yunnan region was not thoroughly integrated into the Chinese administrative hierarchy until 1681. During World War II, Yunnan was a vital link in the communications between Chungking, Chengtu, Kweiyang, and Burma. In 1941 an Anglo-Chinese agreement was signed delimiting the Sino-Burmese border, and construction was begun on a railway between Kunming and Lashio, Burma. After occupying Lashio and closing the Burma Road in 1942, the Japanese advanced further into Yunnan Province to the headwaters of the Salween River and assumed control of Tengchung.

On Oct. 1, 1960, a boundary treaty, delimiting the Yunnan-Burma border, was signed by Burma and China, followed by a protocol signed in Peking on Oct. 13, 1961, which further defined the frontier agreed on in the 1960 treaty.

YUPANQUI PACHACUTI, *yō-pāng'kē pā'chā-kōō-tē'*, or **YUPANQUI PACHACUTEC**, *yō-pāng'kē pā'chā-kōō-tēk'*, ninth Inca sovereign: r. 1438-1471. Second son of the Inca Viracocha, he saved his small nation from being overwhelmed by the Chancas and, having seized power from his brother Urco, founded an empire that he enlarged to include nearly all the present territory of Peru. His adopted title Pachacuti means "cataclysm" or "he who changes the world." Yupanqui was an able administrator, one of his most effective innovations being the transplantation of colonists (*mitimaes*) from one conquered province to another to prevent rebellion. He was the founder of the Inca state religion and developed a system of paternalistic government that kept his empire intact for almost 100 years. See also INCA.

YURACARÉ INDIANS or **YURAKARÉ INDIANS**, *yō-rā-kā-rā'*, a people living at the headwaters of the western tributaries of the Mamoré River, north of Cochabamba, Bolivia. They number close to 1,000. The Yuracaré are tropical-forest farmers who supplement their diet by hunting and fishing. Both men and women dress in bark-cloth tunics; the men's reach below the knee and are decorated with elaborate patterns applied with carved wooden stamps.

The Yuracaré are divided into two major bands, each consisting of a number of small independent family groups. They are predominantly monogamous, and marriage is within the local group. Social control is effected by formal duels, fought with arrows fitted with special points that wound but do not pierce deeply enough to kill. The Yuracaré language is not known to be related to any other.

JOHN HOWLAND ROWE.

YUROK INDIANS, *yō'rōk* (from Karok word for "downstream"), a large and important North American Indian tribe of the Weitspekan linguistic family, living along the lower Klamath River and coastal California. They call themselves *Olekwo'l*, meaning "persons," a term used by many Indian tribes in referring to themselves. Until the entry of gold seekers about 1850, these

people had almost no contact with whites; at that time they numbered about 2,500. They were fortunate in living in an area that the whites did not particularly covet, and probably for this reason they have remained virtually unmolested even to the present time.

In stature, the Yurok are among the tallest of the California tribes; they are physically well built and have developed a culture pattern somewhat beyond that of their immediate neighbors. Together with the Karok and the Hupa, they seem to form a distinct ethnographic group, yet the three do not appear to be linguistically related. The Yurok lived off fish, primarily salmon and lamprey, supplemented by acorns and small game. Clothing was scanty, save for ceremonial costumes, which had elaborate feather ornamentation. Living in the midst of the great redwoods, the Yurok made extensive use of this resource for the construction of their plank houses and their one-piece canoes.

The Yurok were essentially a peaceful people, and such wars as are known were usually the result of individual clashes or occasional raids to avenge a wrong. The women, who tattooed themselves in the custom common to many parts of California, were excellent basketmakers and wove a wide variety of beautiful containers. One of the more characteristic articles was the woman's basketry cap, worn to protect the head against the tumpline of a burden basket. The Yurok were one of the more artistic of northern California peoples and developed ceremonialism to a high art, their decorations being effected by means of such articles as woodpecker feathers, abalone shells, wood, bones, and obsidian. Obsidian and dentalium shells constituted the Yurok currency, which had a standard of value widely understood and accepted. Purses for holding shell currency were made from elk antlers. Tobacco was grown for smoking, and a peculiar straight pipe, with steatite bowl, was used by the men.

Yurok religious beliefs were complex; basically, they centered around an annual ceremony designed to renew the world—a sort of New Year rite. Other ceremonies were the Jumping Dance and the White Deerskin Dance, during which great obsidian blades were brought out from safekeeping and displayed for all to see. This was an extremely impressive event, somewhat equivalent to the modern custom of promenading at a formal dance, wearing all of one's most precious jewelry. Curative powers were vested in female shamans. There are fewer than 500 Yurok surviving today, most of them full bloods.

Foundation, New York City.

YVES OF BRITTANY, *ēv, brī't'an-ē*, SAINT (sometimes IVES; Lat., *Ivo*), French lawyer and cleric, patron saint of lawyers: b. Kermartin, near Tréguier, Côtes-du-Nord, France, Oct. 17, 1253; d. Louannec, May 19, 1303. Son of Hélor, lord of the manor of Kermartin, he was educated in civil and canon law and in 1280 was appointed "official" (ecclesiastical judge) at Rennes. There he came to the attention of the bishop of Tréguier, who had him ordained priest in 1284, after which he was assigned to the rectories of Trédrez (1285) and Louannec (1292). A zealous defender and benefactor of the poor, he was canonized by Pope Clement VI in 1347. His feast day is May 19.

Z	EARLY NORTH SEMITIC	PHOENICIAN	EARLY HEBREW (GEZER)					CLASSICAL LATIN
	I	I	𐤆					Z
	CURSIVE MAJUSCULE (ROMAN)	CURSIVE MINUSCULE (ROMAN)				VENETIAN MINUSCULE (ITALIC)	MODERN ROMAN	
	Ź	z				z	z	

A. C. SYLVESTER, CAMBRIDGE, ENGLAND

The development of the letter Z is illustrated in the chart above, beginning with the early north Semitic letter. The evolution of the majuscule (capital) is shown at top; that of the minuscule (lowercase) at bottom.

Z, zē, Brit. zēd, the last letter of the English alphabet. Its prototype exists in the earliest Semitic scripts—Phoenician (c. 1200 B.C.), proto-Sinaitic (c. 1700 B.C.), the pseudohieroglyphic of Byblos (some three centuries earlier still) and in the Ras Shamra cuneiform of about 1500 B.C. It has not been identified in Egyptian hieroglyphic, although the much later Meroitic inscriptions (2d to 4th centuries A.D.) have a sign that is read z, but it has no relation to the Semitic signs. From the latter, called *zayin* in Hebrew, a name doubtfully interpreted as "weapon" (by others as "olive" or "balance"), came the Greek *zēta*, confused with *xei* (ξ) in some places, much as Greek *xenodochium* is sometimes now written in English with z instead of x. In Greek the symbol preserves its original numerical value (seven), and also in the Cyrillic (Slavonic) alphabet. The name of the letter, probably not from Semitic *sādē* (a different sound), seems to have been modeled on those of the two following letters, *eta* and *theta*.

Latin had no z-sound, except briefly from s between vowels on its way to becoming r, and therefore dropped z, putting the newly invented G (see that article) in its place. But Z existed in Etruscan and Italic scripts (in Oscan and Umbrian with the value ts). Oscan had the sound z, written at first s, but, following Latin in usage, later on as z; for example, *zicolom*, "day" (with z from *di*; compare Latin *dies*, also "day"). Greek ζ was properly dz, not zd or z. In fact, z was usually written s, as in *μίσγω*, "mix," or in *Smyrna*. When z was reintroduced into Latin, in the 1st century B.C., it was restricted to Greek words (for example, *zona*, previously written *sona*), and in some old borrowings z never prevailed (for example, *μάζα* written *massa*, whence French *masse*, English *mass*).

The Latin name of the letter is given as *zēta* by Ausonius, and this appears in Old French as *zēde* or *zé*, of which the former is still in use and has been borrowed into English (sometimes in the corrupt form *izzard*), though *zee* (from *zé*) has now become the usual name in the United States. Old English has z rarely, in late loan-words and with the value ts; the sound did exist but was written s (for example, *bosm*, "bosom," *nosu*, "nose," precisely like modern English spelling). In late Latin, both *gi* and *di* became z by the end of the Empire and thus became confused both with one another and also with i between vowels, and we get *oze* for *hodie*, "to-day," and *zaconus* (*diaconus*), *zunior* (*junior*), and even contrariwise *baptidare* for *baptizare*. This evidence indicates two pronunciations, a

popular y-sound and a cultured dz-sound. Different stages in the development appear in English in such spellings as *ielous* and *gelows* in John Wycliffe, now *jealous*, in contrast with the much later learned form *zealous*, with a different meaning, from late Latin *zelosus*. Further, z is used for the voiced form of s (*sh*), for example in *seizure*—a sound also written s (*leisure*); *si* (*decision*); *ti* (*position*); *xi* (*crucifixion*, *genuflexion*) where the Latin supine had x (*fixum*, *flexum*), *cti* otherwise (*restriction*, from Latin *strictum*), now common in *connection*, and even *g* (*rouge*). The French *cedilla* (*cédille*), as its name "little z" indicates was originally z (Z), now conventionalized as ç but pronounced s (for example, *façade*, *reçu*). The use of 3 in the meaning "ounce" in apothecaries' measure, like the modern abbreviation *oz*, comes from the 15th century Italian *onza* (and this from Latin *uncia*), written *ōz*.

ZAANDAM, zān-dām', city, the Netherlands, in North Holland Province, on the Zaan River near its junction with the North Sea Canal, six miles north-northwest of Amsterdam. It is the center of the Zaanstreek industrial area and has lumber and dye industries. The picturesque Zaan district is intersected by narrow canals with individual boat docks attached to most of the houses. Emperor Peter I the Great of Russia worked here in 1697 in the shipyards, which at that time were a major industry in Zaandam. Pop. (1970) 63,500.

ZAB RIVER, Great, zāb (anc. Lycus), rivē, Turkey and Iraq, rising in the Hakāri Mountains in Turkish Kurdistan. Its upper course is southeast for 115 miles in Turkey, after which it crosses into Iraq and continues south for 150 miles, entering the Tigris 25 miles south of Mosul.

The LITTLE ZAB RIVER (anc. CAPRUS) rises in Azerbaijan, Iran, and flows 250 miles southwest, joining the Tigris 75 miles southeast of Mosul.

ZABRZE, zāb'zhē, city, Poland, in Katowice Province, 11 miles west-northwest of Katowice. Situated in the rich coal and iron area of Silesia, it is a rail, coal-mining, and steel-milling center. Manufacturers include machinery, chemicals, and glass. Zabrze was founded in the 13th century and incorporated into Prussia in 1742. It was renamed Hindenburg in 1915 in honor of Field Marshal Paul von Hindenburg. The city was returned to Poland in 1945. Pop. (1970) 197,200.

ZACAPA, sā-cā'pā, department, Guatemala, 1,039 square miles in area, in the eastern part of the country, on the Honduras border, in the Motagua River valley between the Sierra de las Minas on the north and the highlands in the south. It is an agricultural area, with corn, yucca, coffee, sugarcane, and tobacco as the chief products. The city of Zacapa (pop. (1964), 30,187) is the capital and chief commercial center of the department. Pop. (1968) 107,000.

ZACATECAS, sā-kā-tā'kās, state, Mexico, on the great central plateau, about 28,122 square miles in area, bounded north by Coahuila, east by San Luis Potosí, south by Aguascalientes, south and west by Jalisco, and west by Durango. The Sierra Madre Occidental runs diagonally northwest to southeast across the state, giving it an average altitude of 7,500 feet. There are plains in the north, and temperate, moderately rainy valleys in the south. Much of the land is desert where only mesquite, maguay, and cacti can grow. The southern forests have been overexploited except in inaccessible regions still covered with ilex, copal, and other timber. Most of the rivers are tributaries of the Río Grande of Santiago, which empties into the Pacific Ocean. Mining has been important since colonial times, the chief riches being silver, gold, copper, and lead; the main mining centers are Zacatecas, the capital; and Fresnillo, Mazapil, Concepción del Oro, Sombrerete, and Ojocaliente. Cattle and sheep are also raised, and Zacatecan mules are famous for their endurance. Pop. (1970) 951,462.

IRENE NICHOLSON

ZACATECAS, city, Mexico, capital of the State of Zacatecas (see ZACATECAS, state), situated in a ravine 8,050 feet above sea level, in the midst of the rugged Sierra Madre Occidental. The town is built in typical highland fashion with steep, narrow streets, often with flights of stone steps. It is surrounded by six spectacular peaks, including El Grillo and La Bufa, the latter with a rock escarpment slashed in brilliant colors.

Zacatecas was founded in 1548 by Juan de Tolosa, who had discovered rich silver deposits nearby on land inhabited by the Zacateco Indians. Tolosa was joined by Cristóbal de Oñate, Diego de Ibarra, and Baltazar Termino de Bañuelos, and the four became perhaps the richest men in Mexico. The city received its royal charter in 1588. By 1832 the rich silver mines had produced bullion valued at 667 million pesos; but as the importance of silver diminished, the city also declined. It has, however, remained of strategic importance. In 1914 Francisco (Pancho) Villa won a battle here, celebrated in the popular *Marcha Zacatecas*.

Zacatecas has many fine colonial buildings, including the Municipal Palace and Law Courts; the Cathedral (begun in 1612) with its beautiful churriqueresque portico and life-size figures of Christ and the Apostles; and the Church of Santo Domingo (begun in 1746), a fine example of Spanish baroque. On La Bufa is located the Chapel of Los Remedios, a pilgrimage shrine of the Huichol Indians of the district. Pop. (1970) 50,251.

IRENE NICHOLSON

ZACCHEUS, zā-kē'as, in the New Testament, the chief publican (tax collector) of Jericho, and the subject of an incident related in Luke 19: 1-10.

In order to see Jesus, who was surrounded by a great throng, Zaccheus climbed a sycamore tree. Jesus bade him "... come down; for today I must abide at thy house." This evoked murmurs from the crowd that Jesus had gone in to lodge with a "sinner." Tradition states that Zaccheus gave up his riches, became a companion of the Apostle Peter, and eventually was appointed bishop of Caesarea.

ZACHARIÄ VON LINGENTHAL, tsä-KHä-rē'ä fön līng'än-täl, Karl Salomo, German legal scholar: b. Meissen, Germany, Sept. 14, 1769; d. Heidelberg, March 27, 1843. After studying jurisprudence at Leipzig and Wittenberg, he was appointed professor of law at the latter university, where he taught from 1798 to 1807, and held the same position at Heidelberg from 1807 until his death. He was active politically as a conservative member of the Baden Parliament from 1820 to 1829. His writings cover practically every branch of jurisprudence, dealing with Roman canon, German, English, and French law, and opened up new fields in legal literature.

KARL EDUARD ZACHARIÄ VON LINGENTHAL (1812-1894), his son, was also a prominent legal scholar, who traveled widely in Europe and the East, making exhaustive researches in Roman and Byzantine law. He was the author of *Jus Graeco-Romanum* (1856-84), a seven-volume work on the sources of Byzantine law.

ZACHARIAS, zāk-ä-rī'as, in the New Testament, the father of John the Baptist and husband of Elisabeth. A priest in the Temple of Jerusalem, he was stricken dumb for refusing to believe the announcement, made by the angel Gabriel, that a son would be born to him and Elisabeth. He recovered his speech at the circumcision of the baby (Luke 1:5-79).

ZACHARIAS, Old Testament prophet. See ZACHARIAH.

ZACHARIAS or **ZACHARY**, zāk-ä-rē, SAINT, pope: b. Calabria, Italy; d. Rome, March 752; r. 741-752. Of Greek parentage, he succeeded St. Gregory III as pope in 741. Zacharias exercised a powerful influence over Liutprand, king of the Lombards, whom he induced to return four cities and the environs to the papacy. He also confirmed the deposition of Childeric III of the Merovingian dynasty as king of the Franks and the elevation of Pepin the Short to the Frankish throne (751). He convened two synods in Rome (743, 745) and addressed important letters to the Byzantine emperor Constantine V, condemning his iconoclastic policies.

ZACHARIAS RHETOR, zāk-ä-rī'as rē'tar (known also as ZACHARIAS SCHOLASTICUS), Greek historian of the Christian Church: fl. 535. A native of Palestine, he studied at Alexandria and Berytus (Beirut, Lebanon), practiced law in Constantinople, and became bishop of Mytilene. Four books, treating the period 450-491, survive in a Syriac version of his *Ecclesiastical History*.

ZACHARY, SAINT. See ZACHARIAS, SAINT.

ZADAR, zā'där (It. ZARA), town, Yugoslavia, in the Dalmatian region of Croatia, on the Adriatic Sea, 72 miles northwest of Split. It is situated at the tip of a peninsula and is separated by the Zadar

Channel from the islands of Ugljan and Pašman, and possesses a fine, natural harbor. Zadar's chief industries are shipbuilding, liqueur manufacture, and food processing, especially the canning of fish. It is also a tourist center.

Zadar has had a turbulent history. About 100 B.C. the Romans occupied the Liburnian town of Iader and renamed it Jadera (the sail). The town was spared during the invasions of Dalmatia by the Avars and Slavs early in the 7th century A.D., and soon afterward it was occupied and made the capital of Dalmatia by the Byzantine emperors. The Croats took the town in 923 but were forced to abandon it to the Venetians before the end of the 10th century. After reverting to Croatian rule (about 1100), it was sacked by the Crusaders (1202) and turned over to Venice. It was subsequently conquered by the Croat-Hungarian kingdom but was sold back to Venice in 1409. After the dissolution of the Venetian Republic by the French in 1797, Zadar was incorporated into the Illyrian Provinces. In 1813 it was obtained by Austria along with the rest of Dalmatia, and it remained under Austrian rule until 1918, when it was captured by the Italians during World War I. The Treaty of Rapallo (1920) confirmed Italy's title. On Nov. 1, 1944, during World War II, the town was captured by Yugoslav forces and awarded to Yugoslavia by the peace treaty with Italy signed in Paris on Feb. 10, 1947.

The town contains important architectural monuments of the Middle Ages and the Renaissance. Notable are the Church of St. Donato (early 9th century), which is now a museum, and the Basilica of St. Anastasia (13th century), decorated with paintings by Jacopo Palma. Pop. (1965) 31,000.

DAVID MACKENZIE

Assistant Professor of History, Wells College

ZAFARIN ISLANDS. See CHAFARINAS ISLANDS.

ZAGAZIG, zāg'ā-zīg (Ar. ZAQAQIḠ), city, Egypt, capital of Sharqiya Province, on the Nile Delta and the Ismailia Canal, 47 miles north-northeast of Cairo. It is connected by rail or canal with the major cities of the Nile Delta and is a cotton and grain market. Two miles southeast are the ruins of the ancient city of Bubastis, now called Tell Basta. Pop. (1970) 173,000.

ZAGHLUL PASHA, zāg-lōōl' pā'shā, Sa'd (Ar. SA'D ZAGHLUL BASHA), Egyptian statesman: b. Ihyannah, Egypt, ?1857; d. Cairo, Aug. 23, 1927. Of wealthy peasant origin, he was educated in religious schools and at the Muslim university of al-Azhar. In 1881 he wrote for the official gazette *al-Waqā'i' al-Misriyah* but was jailed for complicity in the Arabi revolt after the British occupation in 1882. Zaghlul was soon released, however, and began to practice law. In 1906 the 1st early of Cromer, the British consul general who actually administered Egypt, chose him minister of education, and in 1910 he was made minister of justice.

During all this period, to the end of World War I, Zaghlul's reputation as a nationalist leader was growing, and on Nov. 13, 1918, he led a delegation to the British high commissioner demanding Egypt's complete independence. This event marks the birth of Egypt's first mass party, the Wafd (Ar. for "delegation"). When the

British refused Zaghlul's request and in 1919 deported him to Malta, revolution swept Egypt; Zaghlul was released and proceeded to the Paris Peace Conference and to London to plead Egypt's cause. After his return home, there was still no settlement, and new disturbances began. The 1st Viscount Allenby, now high commissioner, deported Sa'd to the Seychelles but also put pressure on London that resulted in a declaration of nominal Egyptian independence (February 1922). Released in 1923, Zaghlul plunged into the electoral campaign that was taking place under the newly promulgated constitution. A Wafd landslide resulted, and Zaghlul became prime minister (1924). His immediate goal was further British concessions. When negotiations failed, serious Wafdist-led disorders reerupted; British reaction was strong, and Zaghlul resigned. New elections (1926) produced another Wafd majority, but the British vetoed Zaghlul for the prime ministry. His colleagues elected him president of the Chamber of Deputies, and he held this post until his death. He was revered by the masses of his compatriots as the father of his country.

Princeton University*

ZAGREB, zā'grēb (Ger. AGRAM), city, Yugoslavia, capital of Croatia, at the foot of Zagreb Mountain (Medvednica), near the Sava River, 230 miles west-northwest of Belgrade. It is the second largest city in Yugoslavia and a chief center of light industry, producing carpets, leather

The Croatian National Theater in Zagreb. The city is the principal Croatian cultural center.

JAMES MASON/BLACK STAR

goods, wood products, and textiles. After World War II electrical and chemical industries were developed on a large scale. Zagreb is connected with Belgrade by highway and railroad and is an important point on routes leading from central Europe into the Balkans and from the Danube River to the Adriatic Sea. There is a large modern airport. The city is also a financial center, and periodic international fairs are held here.

Site of an old Roman settlement, Zagreb first became prominent in 1091 when King Ladislas I of Hungary established a bishopric here. After being ravaged by the Mongols in 1242, it was rebuilt and became a royal free city under the Hungarian crown, and from the second half of the 13th century was the chief town of Croatia and Slavonia. When the Austro-Hungarian monarchy was reorganized in 1867, Zagreb was made the capital of autonomous Croatia and the seat of the Croatian Diet (Sejm). After World War I, when the new Kingdom of Yugoslavia, including Croatia, was formed, the city lost its status as a capital; but it served during World War II as the capital of the Independent State of Croatia, headed by Ante Pavelić, and remained the capital of the Croatian republic in the reconstituted Yugoslav state after 1945.

Zagreb is the main center of Roman Catholicism in Yugoslavia, and possesses a fine 17th century Gothic cathedral and an 18th century archiepiscopal palace. For centuries, it has been the principal Croatian cultural center. Among its institutions are the University of Zagreb (see ZAGREB, UNIVERSITY OF), academies of music,

fine arts, and applied arts, the Yugoslav Academy of Sciences and Arts, and the Rudjer Bosković Institute for nuclear energy research. Population: (1981 census) 649,586.

DAVID MACKENZIE

University of North Carolina at Greensboro

ZAGREB, ză'grĕb, *University of*, a coeducational institution of higher learning in Zagreb, Croatia, Yugoslavia, with branches in Zadar, Rijeka, Split, and Osijek. It comprises faculties of law, economics, philosophy, natural sciences and mathematics, medicine, veterinary medicine, pharmacy, architecture, technology, agriculture, forestry, mechanical and naval engineering, and others. The university, chartered under its present name in 1869 and opened in 1874, grew out of the Jesuit Academy (chartered 1669), the Royal Public School for political and financial sciences (founded at Varaždin in 1769), and a Royal Academy of Sciences (1776). In the 19th century it played an important role in the Croatian national revival. Its library is particularly rich in Croatian literature.

ZAGROS MOUNTAINS, zăg'rəs, mountain range. Iran, in the western and southern part of the country, extending 1,000 miles (1,600 km) south and east from the "Armenian knot" to the Persian Gulf. The range varies in width from 100 to 200 miles (160–320 km), and many elevations exceed 10,000 feet (3,000 meters), with Zardeh Kuh at almost 15,000 feet (4,500 meters) the highest, and Dinar Kuh and Kuh-i-Rang nearly as high.

The Zagros are basically calcareous and in their central and southern regions are formed primarily by folding. In the north they are mainly faulted, with large upthrust blocks giving the appearance of a plateau; numerous volcanic cones occur along the fault lines.

In winter, snow covers the peaks, giving way in spring to alpine meadows. Only small forested areas remain at higher elevations, while the lower flanks support only scattered herbaceous vegetation. One of the world's most productive oilfields is found in the foothill region to the west, occurring in the broad limestone anticlines at the fringe of the uplift.

The most important group inhabiting the Zagros are Kurds. Seasonal migration to graze sheep and goats (to the upland meadows in summer and to the lowlands in winter) dictates the Kurds way of life. In the northwest, around Lake Urmia, is an important wheat-producing area.

ZAHARIAS, za-hă-rĭ'əs, *Babe Didrikson* (1914–1956), American athlete. Mildred Ella Didrikson was born in Port Arthur, Texas, on June 26 1914. The daughter of Norwegian immigrants she was raised in Beaumont, Texas. She began her sports career in basketball with an insurance company team and was named an all-American in 1939–1941.

In 1932 she gained national acclaim by winning 8 of 10 events in the Amateur Athletic Union's national women's track and field championships, including the 80-meter hurdles, baseball throw, shotput, broad jump, and javelin throw. Later that year at the Olympic games she set two world records—the javelin throw (143 feet 4 inches, or 43.68 meters) and the 80-meter hurdles (11.7 seconds).

After the 1932 Olympics, Miss Didrikson became a professional athlete and spent the next

Babe Didrikson Zaharias excelled in many sports.

years playing basketball and baseball, excelling as well in billiards, swimming, diving, and other sports. In 1938 she married George Zaharias, a professional wrestler. She started her championship record in golf in 1940 and won every available women's title at least once during the next decade. In 1950 she was chosen by an Associated Press poll as the outstanding woman athlete of the first half of the 20th century. She was stricken with cancer in 1953 and died in Galveston, Texas, on Sept. 27, 1956. Her autobiography, *This Life I've Led*, appeared in 1955.

ZAHAROFF, zə-hā'róf, Sir Basil (1850?-1936), international armaments salesman and financier. He was born in Constantinople (Istanbul), Turkey, on Oct. 20, 1850, or in Mugla, Turkey, on Oct. 6, 1849. The son of a Russian (or Greek) father and Greek mother, he has been called the "mystery man of Europe," and the events of his life have been obscured by fable or design. About 1875 he became the representative in the Balkans of the munitions firm of Torsten Wilhelm Nordenfeldt; he was later associated in turn with the firms of Hiram Stevens Maxim and Vickers, and became one of the world's most successful armaments salesmen. Critics have attributed his immense wealth to political intrigue and the sale of munitions to both sides before and during wars. He eventually became a British subject and was knighted in 1918 for his services to the Allies in World War I. He died in Monte Carlo, Monaco, on Nov. 27, 1936.

Zaharoff was an intimate of many leading European statesmen, including David Lloyd George, Georges Clemenceau, Aristide Briand, and Eleutherios Venizelos. In his later years, he acquired substantial interests in petroleum, banking, and shipping, and was reputed to be an owner of the gambling casino at Monte Carlo. He was lavish in his philanthropies.

ZÄHRINGEN, tsä'ring-on, a dynasty of German rulers, named after the ancient village and castle of Zähringen, now part of Freiburg, in the state of Baden-Württemberg, in southwestern West Germany (Federal Republic of Germany).

The elder line temporarily gained possession of the duchy of Carinthia and Mark Verona in 1061 and ruled western Switzerland after 1152. This line expired in 1218. The members of the younger line called themselves margraves of Baden from the 12th century onward. Their territories were split in 1535 between a Baden-Baden and a Baden-Durlach line.

Among the rulers of the Baden-Baden line, who were Roman Catholics, Margrave Louis William I (reigned 1677-1707) gained great distinction in the Turkish wars of the 1680's. In Baden-Durlach, where the rulers became Lutherans, Margrave Charles Frederick (reigned 1738-1811) won a high reputation as one of the most enlightened European princes. In 1771 he inherited Baden-Baden also, and the demise of the Holy Roman Empire gave him, with the French Emperor Napoleon I's approval, additional territories beyond his old patrimony. Among these were the Austrian Breisgau and the sections of the Rhenish Palatinate on the right bank of the Rhine, including Heidelberg and Mannheim. In 1806 this enlarged Baden became a grand duchy, under Charles Frederick. From 1814 to 1866 it belonged to the German Confederation.

During the 19th century the Zähringen rulers were the most liberal of the German dynasts. They gave the state a constitution in 1818, and Frederick I (reigned 1856-1907) played an important part in German unification. Maximilian (Prince Max), the heir presumptive to the Baden throne, as chancellor of the Reich in October-November 1918, democratized the German constitution and conducted the negotiations for an armistice with the Allies. The last grand duke, Frederick II, abdicated after the revolution of November 1918.

ZAIBATSU, zi-bät-sōō, industrial or financial combines in Japan. The great zaibatsu firms include Mitsui, Mitsubishi, Sumitomo, and Yasuda. See under ANTITRUST LAWS.

ZAÏMIS, zä-ē'mēs, Alexandros (1855-1936), Greek premier and president. He was born in Athens on Oct. 28, 1855, and educated at the universities of Athens, Heidelberg, and Paris. In 1885 he was elected to Parliament. After serving as minister of justice (1890-1892), he was premier in 1897-1899 and held this office again for brief periods in 1915, 1916, and 1917.

Both Zaïmis and his rival Eleutherios Venizelos, the Cretan political leader, favored Greece's entry in World War I on the side of the Allies. When King Constantine I, who was impressed by Germany's military power, insisted on neutrality, Venizelos formed a separate government in Salonika. Zaïmis, however, sided with the king. When Constantine abdicated under Anglo-French pressure in 1917, Zaïmis resigned as premier in favor of Venizelos.

After Greece became a republic in the 1920's, Zaïmis was elected president in 1929 and reelected in 1934. He died in Vienna, Austria, on Sept. 15, 1936.

AGENCE ZAIREPRESSED

Kinshasa, the capital of Zaire, is one of the largest cities in tropical Africa. It is situated on the Zaire River, at the point where freight from the interior must be moved by road or rail around falls to a seaport.

ZAIRE, zä-ër', a country in Equatorial Africa. It occupies most of the basin of the Zaire River, which is still known outside of Zaire as the Congo River. Formerly a Belgian colony called the Belgian Congo, the nation achieved independence on June 30, 1960, and adopted the name Republic of the Congo. The formal designation of the country was changed to Democratic Republic of Congo on Aug. 1, 1964. The country was frequently referred to, in conjunction with its capital, as "Congo (Kinshasa)" to distinguish it from the neighboring People's Republic of the Congo, or "Congo (Brazzaville)."

The Democratic Republic of Congo changed its name to the Republic of Zaire on Oct. 27, 1971. The new name was taken from the name given by Portuguese explorers to the Congo River, based on an approximate rendering of the KiKongo word *nzadi* ("river"). In French, the name takes a diaeresis: Zaire.

1. The People

Ethnically, Zaire is more homogeneous than many countries in Africa. All of its inhabitants except the Pygmies belong to the group identified by the anthropologist George Peter Murdock as Melano-Africans, and 90% of them fall into the "Congolese" sub-group. Sudanese and Nilotic

peoples live only on the northern and eastern fringes, mostly as "spillovers" from the neighboring northern and eastern states—the Central African Republic, the Sudan, Uganda, Rwanda, and Burundi.

Distribution of population is uneven, with the greatest concentration occurring along the edge of the equatorial forest, which covers most of the semicircular area encompassed by the Zaire River. Thus population density is highest in the areas south of the Zaire-Kasai-Sankuru river system and along the eastern border of the country.

Society. Semisedentary agriculture characterizes the way of life of the people of Zaire. Depending on the environment in which agriculture is practiced, the traditional economies of Zaire are of two basic types. In the tropical rain forest, farming is practiced in clearings made by relatively small groups of people. Therefore,

INFORMATION HIGHLIGHTS

Area: 905,563 square miles (2,345,409 sq km).
Boundaries: North, Central African Republic and Sudan; east, Uganda, Rwanda, Burundi, and Tanzania; south, Zambia and Angola; west, Atlantic Ocean, Angola, and Congo.
Elevations: Highest—Margherita Peak (16,762 feet, or 5,109 meters); lowest—sea level.
Population: (1984 census) 29,671,407.
Capital and Largest City: Kinshasa.
Name of Nationals: Zairians.
Major Languages: French (official), LiNgala, KiSwahili, KiKongo, and CiLuba.
Major Religious Groups: Roman Catholics, Protestants, Kimbanguists, and followers of traditional African religions.
Monetary Unit: Zaire (= 100 makuta).
 For Zaire's flag, see under FLAG, both illustration and text.

the farming community is usually small, always close-knit, and often isolated. In the savanna, on the other hand, farming can be practiced on a wider scale by larger communities. While the difference in output between the two types of farming is not considerable, there is a wide socio-political gap between the two types of economy. In the tropical rain forest, kinship ties and village political organization remain so tightly intertwined as to be indistinguishable. Savanna agriculture, on the other hand, is just high enough above the subsistence level to be able to produce a surplus, and the administration of this surplus requires a more intricate form of political organization. The terrain also makes it possible for political authority to spread over a wider area in the savanna, and historically the territorial state appears. The difference between the two types of economy is so striking that they have been contrasted as "the civilization of the clearings" and "the civilization of granaries."

Class stratification in Zairian societies seldom reached the rigidity and economic inevitability apparent in societies like those of Rwanda or northern Nigeria. This was true even in those societies where role differentiation had reached some degree of complexity. Nor had subjugation

as a result of military conquest produced the military-bureaucratic patterns of northern Nigeria and the lacustrine (lake) kingdoms of East Africa. What social classes existed, such as courtiers, warriors, artisans, serfs, and slaves, became obscured with the advent of colonial rule. Socially, the European intrusions in the late 19th century resulted in a relative increase of mobility within the African societies and a relative obscuring of precolonial class distinctions as a result of the superimposition of a new economically privileged ruling class—the Europeans.

Urbanization and economic development produced a large mass of detribalized Africans who—without necessarily breaking entirely with the tribal society—were now in a position to attain wealth and status hitherto unavailable to them in their traditional environment. Traditional political organizations were weakened or even shattered by the drain on the adult male population and by Belgian administrative policy, which left little autonomy to the chiefs. On the eve of independence, nearly one fourth of the population was affected by urbanization—or rather by the process of detribalization.

Today about one half of the population lives in the urban centers of Zaire. Kinshasa (formerly

Léopoldville) is the capital and largest city of the country. The other major cities include Lubumbashi (formerly Elisabethville), Kisangani (Stanleyville), Kananga (Luluabourg), and Mbuji-Mayi (Bakwanga). Matadi, near the mouth of the Zaire River, is the country's major port.

"Tribes." The concept of the tribe is an elusive one—and particularly so in Zaire. Common misconceptions abound on this subject. Reference to Zaire's "200 tribes" is misleading because it overlooks a number of factors:

(1) Groups sometimes identified as "tribes" are in fact the agglomeration of a number of smaller groups. This is true of the BaLuba and, more specifically, of the BaKongo, who have reached their present state of "national consciousness" through a comparatively recent process. Factors such as the deliberate glorification of the former Kongo Kingdom, the catalytic role of a native sect (Kimbanguism), and a search for identity in the multitribal environment of Kinshasa all played a part in and were used by a political formation—Alliance des BaKongo (ABAKO).

(2) Groups bearing the same name can be quite different in language, shared experience, and even in kinship systems. Such is the case with the BaLuba of Kasai and Shaba (Katanga).

(3) What is commonly described as "inter-tribal" fighting often occurs between subgroups (such as clans) of the same "tribe."

(4) Groups that never had common political institutions may enjoy a sense of commonality or at least of "apartness" from other groups (the BaMongo).

Tribalism as it is known today, with its implications in terms of political affiliation, apportionment, appointments, patronage, and other political behavior, is mainly a product of the urban, and not of the rural, environment. The search for identity does not arise in the traditional environment, where each man is clearly inserted into his lineage, clan, and tribal patterns. When he moves to the city, the African is naturally led to seek association with members of his traditional environment. The significant factor about tribalism is that it acts as a protection for insecure men of the cities rather than as a tradition-rooted force.

Two factors furthered the trend toward urban tribalism. First, the housing patterns developed by the European colonizers "to avoid trouble" usually followed real or assumed ethnic patterns. Second, all those supposedly belonging to the same "tribe," regardless of finer distinctions, were often lumped together under a label by those apart from the group. This lumping together was eventually accepted by those who were labeled, if only for ease of communication or out of vague pride in belonging to a group assumed to be larger than it really was. It is notable that the smaller the number of one's compatriots in the city, the larger the group with which one seeks identification. Thus it was, and still is, common for people from the Kasai region to identify themselves as BaLuba (or even as BaKasai, which denotes regional, not tribal, origin) even if they were, in fact, members of a smaller, lesser-known group. Identification was made easier by the fact that the individual's real tribe and the one with which he sought to be identified, while different, probably had more in common than any other two groups. There may also have been a desire to identify with a group regarded as more prestigious, if only in the eyes of the Europeans.

Language. The vast majority of Zairians speak one of several Bantu languages, some of which are mutually intelligible and all of which have the same grammatical structure. Vehicular languages have evolved in several areas of the country. For example, LiNgala is used along the Zaire River, from Kinshasa to Kisangani, and throughout the country by the Zairian army. A form of KiSwahili sprinkled with local dialectal terms is used from the Ituri Forest region in the northeast down to Shaba. KiKongo is used in the Lower Zaire and Bandundu regions of the southwest, while CiLuba is used in Kasai. French, spoken by all educated Zairians is the official language of the country.

Religion. Traditional religions of the Zairian people are a complex blend of rites and beliefs overlying an implicit philosophy built around the concept of a "life force." Rites associated with the cult of ancestors or with passage are common throughout the area and help provide social and political cohesion. Beliefs usually refer to the

Housewives shopping in Kinshasa's biggest market. Life in Zaire, as in many other African countries, is a mixture of traditional customs and very modern Western practices.

spirit world and reflect the human desire for "logical" explanations of illness, accidents, death, fertility (of the earth or of women), and success or failure in war, love, agriculture, and other human experience. Propitiation of all causal forces is sought by appropriate ritual, while divination is chiefly intended to uncover the person or persons who are exercising a nefarious influence.

For a large number of African converts, Christianity appears to have been indissolubly linked with Western colonial rule and with its claims of moral superiority, supported mostly by the material superiority, of European civilization. The adoption of Western religion was seen by many as instrumental to the securing of the power and wealth of Europeans. When this goal was not realized, various phenomena occurred, ranging from outright rejection of Christianity to the

development of dozens of native Christian sects expressing the African's yearning for a form of Christianity revealed through Africans. The most important of these sects are Kitawala, an offshoot of the Watch Tower (Jehovah's Witnesses) movement; and the Kimbanguist church (Church of Jesus Christ on Earth Through the Prophet Simon Kimbangu). Based on the brief pastoral career of Simon Kimbangu in the lower Congo area in 1921, the Kimbanguist movement survived persecution by the colonial and missionary authorities and emerged as a powerful cement of BaKongo national unity in the 1950's. In 1972 the government consolidated all Protestant denominations with the exception of the Kimbanguist church into a single organization, the Church of Christ in Zaire, thereby indirectly denying official existence to a large number of independent sects.

Indigenous Muslims are few. Most are the descendants of East African coast traders of mixed Arab and African ancestry, who were operating in eastern Zaire during the 19th century.

2. Education

The Belgian Congo was notorious for its lack of a university-trained elite, but its recorded percentage of elementary school attendance—56% in 1959—was one of the highest in Africa. This figure was deceptive, however, because elementary schooling was limited in most cases to the first two grades. Fewer than 10% of the school-age children ever completed the six-year elementary cycle. Understandably, one of the chief efforts of the Zairian government has been to push as many schoolchildren as possible beyond the two-year cycle, which is virtually useless unless followed by further schooling.

Education remained, as it was before independence, a virtual monopoly of the Christian missions, although placed under the supervision of a government ministry. More than two thirds of all elementary-school children attend schools staffed by Roman Catholic missions, and another 25% attend Protestant or Kimbanguist schools. Physical hardship forced the discontinuation of several hundred "bush" schools during the mid-1960's, but many of them later reopened.

Only a limited number of secondary-school students are able to enter institutions of higher learning. In 1970, 60% of these students were enrolled at one of the country's three universities: Lovanium University of Kinshasa (Catholic), the State University at Lubumbashi, and the Free University of the Congo at Kisangani (Protestant). In 1971, however, these three universities were combined with other institutions of higher learning such as the National Institute of Mines, the National Pedagogical Institute, and the National School of Law and Administration, to form a single, nondenominational National University of Zaire (UNAZA). In 1981 the na-

tional university was reorganized as the separate universities of Kinshasa, Kisangani, and Lubumbashi.

3. The Land

Zaire is the largest country lying entirely within sub-Saharan Africa. Although its frontiers were drawn up around conference tables, Zaire has more "logical" boundaries than most new African states. The approximately 3,000-mile (5,000-km) course of the Zaire River, from headwaters to estuary, lies almost wholly within the territory of the republic, and the Zaire-Nile and Zaire-Zambezi watersheds demarcate most of the country's eastern perimeter.

Geography and Climate. The critical climatic feature in Zaire is the equatorial zone, which stretches across the entire country over an area approximately four degrees in latitude on either side of the equator. This climatic zone roughly coincides with the equatorial forest belt running from Uganda to the coast of Gabon. To the north and south of this belt lie two zones of tropical wet and dry climate with which park forest and savanna vegetation are associated. Because Zaire stretches from latitude 5° N to 13° S, the southern savanna belt is much more extensive than the northern one and the material cultures that grew up in this southern savanna have had greater historical significance for the country. Toward the southeast the savanna becomes increasingly wooded, and the climate changes from an alternating pattern of two wet and two dry seasons to that of one wet and one dry season. Finally, all along the Great Rift Valley, which forms the eastern border of Zaire, particular soil, rainfall, and elevation combine to form a narrow, highly distinctive geographical fringe zone.

With the exception of the southeasternmost corner of Zaire, rainfall is abundant throughout the country. It averages well over 40 inches (1,000 mm) annually and rises to more than 80 inches (2,000 mm) along the Great Rift Valley

and in the low-lying area delineated by the gigantic bend in the Zaire River. Around this central depression, known as the *cuvette*, which has an average elevation of 1,300 feet (400 meters), a succession of plateaus rises gradually to elevations of over 5,000 feet (1,500 meters) in the northeast and southeast. Highest elevations, however, are found along the Great Rift Valley. Here dislocation of the strata has produced important mountain masses, most notable of which is the Ruwenzori, with its highest peak rising to 16,762 feet (5,109 meters).

Soil. The soil of Zaire is generally poor. The topsoil is subject to erosion and to the formation of laterite crusts often spreading over huge areas. Laterite is the result of surface crystallization of iron oxides or aluminum hydroxides of such thickness as to preclude any significant form of agriculture. Since good soils are comparatively rare, overpopulation is common in the fertile areas. These are mainly strips of alluvial deposits along the Kasai River and its many tributaries, or volcanic soils of the Great Rift Valley, especially of the Kivu region.

Animals and Plants. Zaire's fauna and flora are among the richest and most varied in the world. An extraordinary number of species have been cataloged—many of them not found anywhere else. Zaire is the home of several "living fossils," or rare species, such as the okapi, the forest and mountain gorillas, the pangolin, and the African manatee. About 10,000 species of flowering plants have been found.

4. The Economy

A country of vast and varied natural resources, Zaire probably has the greatest potential for economic growth in all sub-Saharan Africa. Indeed, many of its resources, such as hydroelectric energy and natural gas deposits, have yet to be fully tapped. The country's natural resources—particularly the minerals—are far from being evenly distributed. Moreover, their exploitation was generally carried out by other than native groups, with the indigenous population participating only indirectly in the process of economic development.

Furthermore, far from being coherent and continuous, Zaire's economic progress has gone through successive phases during which widely different forms of exploitation were emphasized. During the first 30 years of European occupation, a predatory economy based on ivory and wild rubber prevailed. This phase came to an end with World War I, partly as a result of humanitarian protests against the forced-labor system on which this type of exploitation was founded and partly because the exhaustion of the ivory supply and the development of rubber plantations in Southeast Asia made Congolese production less and less competitive. A more systematic effort toward the development of an efficient plantation economy was started after Belgium took over the Congo Free State in 1908. The fluctuations of the world market at the time, however, made it difficult for all but the larger rubber manufacturers, such as Unilever, to survive.

The mining industry, launched shortly before World War I, brought the colony its most spectacular and characteristic development. Even more than plantation farming, however, mining requires large investments and economic concentration. In addition, because the more important mineral deposits were found mostly in sparsely

populated areas, their exploitation led to large-scale migration and urbanization, which in turn caused widespread disruption of indigenous agriculture.

Agriculture. The agriculture of the Zairians is based mostly on American crops introduced in the 16th century, such as cassava, maize (corn), sweet potatoes, and peanuts, or on plantain bananas, an earlier Asian import. Indigenous African crops such as pulses, millet, sorghum, and yams are also important. Traditional farming relies on methods such as brush burning, long-term crop rotation, and the use of the hoe, all of which are suited to the poor soil conditions but are not conducive to high productivity. Some cattle are grazed in the eastern highlands. Fishing, hunting, and goat and poultry raising add protein to the generally inadequate diet.

European colonization resulted in the development of marketable food and industrial crops. Indeed, the cultivation of such crops was made compulsory for traditional communities as early as 1917. The principal cash crops are coffee, palm products, cotton, rubber, tea, cocoa, and tobacco.

Mining and Energy Production. Mining, including oil extraction, is the mainstay of the Zairian export economy. With the exception of diamonds and oil, most of the mineral wealth is concentrated in the Shaba (formerly Katanga) region. Zaire is usually ranked first in world production of cobalt and industrial diamonds, and it is among the leading suppliers of copper. It also produces cadmium, gold, manganese, silver, tan-

A sheet of copper refined by electrolysis in the Shaba (formerly Katanga) region. Shaba is Zaire's copper belt.

talum, tin, tungsten, and zinc. Oil is tapped off the country's short Atlantic coastline. Sufficient quantities of coal were found in Shaba to fuel smelting operations until that source of energy was superseded by hydroelectric power on the upper Lualaba and Lufira rivers. But the most promising source of energy remains the huge Inga hydroelectric scheme, which was constructed on the lower Zaire River near Matadi.

Manufacturing. As in many developing countries, manufacturing in Zaire was initially limited to the processing of primary products. At a later stage, textile mills, breweries, and factories to produce such items as soap, shoes, and construction materials were set up. More recently mining companies sponsored the production, through subsidiaries, of chemicals, nails, wires, pipes, metal cans, and household articles. Other miscellaneous industries such as textiles and plastics production, automobile and bicycle assembly, and the manufacture of cigarettes and paints and varnishes have also been developed.

Partly because Belgian imports had been denied preferential treatment under international tariff agreements, manufacturing was always more developed in Zaire than in almost any other tropical colony. After independence, monetary instability acted as a spur for the manufacturing of consumer products that hitherto had been purchased abroad.

Trade. Zaire's chief exports are copper, crude oil, industrial diamonds, cobalt, and coffee. Principal imports include machinery, transportation equipment, petroleum products, chemicals, clothing, and foodstuffs.

Belgium has always been the chief buyer of Zairian products and usually has been Zaire's chief supplier of imports. Other Western European countries also are important trading partners of Zaire, as are the United States and Japan.

Transportation. From the day that the 19th century explorer Henry Morton Stanley remarked that the Congo without a railroad was not

worth a penny, transportation has been one of the country's major problems. Zaire has a vast inland water system, and the Belgians developed rail transportation primarily to supplement the available waterways. Therefore the only rail links along the middle and lower course of the Zaire River are two short lines that bypass the Boyoma (Stanley) Falls, near Kisangani, and the lower Zaire rapids. The major cities of Kinshasa and Kisangani owe their existence to the need for transshipment of cargo at these two critical locations.

The absence of navigable waterways in Shaba prompted the construction of a well-developed rail network. It connects this mineral-rich area with the Zairian seaport of Matadi, via the rail-ship-rail "national route" (using river transportation between Ilebo and Kinshasa) and, more directly, with the Angolan port of Lobito on the Atlantic Ocean and the Mozambican port of Beira on the Indian Ocean (by all-rail routes). A less important railroad connects the national route with Kalemie on Lake Tanganyika. Steamers on Lake Tanganyika provide a connection with the Tanzanian port of Kigoma, on the opposite shore, and an all-rail route extends from there to Dar es Salaam.

Zaire's 3,000 miles (5,000 km) of railroads and 10,000 miles (16,000 km) of navigable waterways are well adapted to the requirements of an export-oriented economy. But they are of limited use for the type of local development projects that the Belgians tried to promote.

Road construction, the obvious answer to the needs of rural development, was not well promoted before 1960. Zaire has only about 90,000 miles (145,000 km) of roads, and unrest in the country following independence resulted in serious deterioration of the existing road network. Aviation, on the other hand, has outpaced the development of surface transportation. The airplane is by far the most common means of passenger transportation for all but purely local trips.

HISTORY AND GOVERNMENT

The Bantu ancestors of the present inhabitants of Zaire may have come from the southeastern portion of modern Nigeria. Most, if not all, of them had reached the Zaire Basin by about 800 A.D. and were equipped with the agricultural and metallurgical skills that were still in use when European rule was established more than 1,000 years later. Pygmy hunters and food gatherers, who were the original inhabitants, were forced to retreat to the more inaccessible parts of the region. During the second half of the 17th century, non-Bantu groups began to infiltrate the northernmost portions of the Zaire Basin.

5. The Congo to 1960

Several major states emerged to the south of the tropical forest belt between the 13th and 19th centuries. The best known was the Kingdom of Kongo, where the monarch embraced Christianity, invited Portuguese trade and technical assistance, and exchanged ambassadors with the courts of Lisbon and the Vatican. Internecine strife, incursions by the warlike Jaga, and conflict with the Portuguese wrecked the kingdom by the end of the 17th century. Thereafter, Kongo's superficial Christianity was engulfed by traditional religion.

Farther to the east the kingdom of the Bakuba deserves notice for its artistic achievements and for the continuity of its oral chronicles. The Songye, on the upper Lomami River, developed an urbanized civilization unique in this part of Africa. During the 1400's a Songye dynasty founded the Luba empire, which reached its height toward the end of the 18th century, when it covered most of modern Shaba. To the south, a modest confederacy of chiefs, which was founded in the late 16th century, developed into the far-flung Lunda empire. At its peak in the mid-17th century, this empire straddled the modern boundaries of Angola, Shaba, and Zambia.

Also in Shaba, an adventurer from Unyamwezi (in modern Tanzania) named Msiri built an ephemeral state during the 19th century. Ruling from his capital at Bunkeya, Msiri established a profitable commercial network. Msiri's state collapsed when he was killed by a Belgian army officer in 1891. In the northeast the most remarkable states were those of the Mangbetu and the Azande. In the eastern lake region, political organization was influenced by the neighboring kingdoms of Rwanda and Burundi.

The Coming of the Europeans. European penetration began with the discovery of the estuary of the Zaire by the Portuguese explorer Diogo Cam (Cão) in 1483. Soon the Portuguese made contact with the king of Kongo. During the next three centuries, traders and missionaries attempted to penetrate the interior by ascending the river, but seldom progressed beyond the site of modern Kinshasa.

Trading by Europeans in slaves brought from the interior developed gradually, reaching its peak in the Zaire Basin between 1800 and 1850, when some 150,000 slaves were shipped from this area each year. Arab slave trade expanded into the region after 1840, and by 1875 the annual shipment of slaves from Mombasa (in Kenya) and Zanzibar exceeded 55,000.

After 1850, European explorers such as David Livingstone, Richard Francis Burton and John Hanning Speke, Sir Samuel Baker, Georg

Schweinfurth, and Sir Donald Cameron reached the periphery of the Zaire Basin. But it was Henry Morton Stanley who first navigated the Zaire River from its upper course to the Atlantic Ocean from 1874 to 1877. He was then hired by Leopold II, king of the Belgians, who had sponsored the creation of an International African Association in 1876. Between 1878 and 1884, Stanley and others set up posts and signed protectorate treaties with local chiefs throughout the region, in the name of another group headed by Leopold. This was known as the International Congo Association.

The Congo Free State. Leopold II was recognized as sovereign of the Congo Free State at the Berlin Conference on Africa (1884-1885). During his rule, military expeditions evicted the Arab traders from the northeast, and a chartered company secured the occupation of Katanga (now Shaba). The Congo Free State was primarily an economic venture and had no institutional links with Belgium. Financial difficulties led to harsh economic exploitation, and mounting international criticism finally prodded Belgium into taking over the Congo Free State as a colony in 1908.

Belgian Colonial Rule. When the Belgian Congo colony was established, the practice of executive rule was continued. After setting up the ground rules of colonial government laid out in the Charte Coloniale of 1908, the Belgian parliament seldom bothered with African affairs. Legislation was enacted by executive decrees issued by the Belgian government in Brussels or, for matters of smaller scope, by the governors-general in Léopoldville (now Kinshasa). Thus the Congo was largely kept out of the mainstream of Belgian political life.

Despite official policy pronouncements favoring a form of indirect rule, traditional chiefs were incorporated into the administrative system principally as auxiliaries of the Belgian officials. Local government institutions—or indeed the very concept of local government—were totally lacking in the Belgian Congo before 1957.

The Belgians attempted to insulate the Congo from metropolitan political life and from the currents of African nationalism. Assuming that political aspirations might be minimized if social and economic needs were adequately met, Belgium promoted a policy of outspoken paternalism in which the administration, the religious missions, and the business circles concurred. Remarkable success was achieved in the fields of health and urban development, but opportunities for advanced education were sharply limited, and important civil rights were denied to the Africans. Permanent white settlement was not encouraged. But by 1959 the white population had grown to 115,157, most of whom lived in Léopoldville and in Katanga.

Achievement of independence. Planned political change, beginning in the early 1950's, was initially aimed at developing a Belgo-Congolese community in the rather remote future. A lack of any real sense of urgency characterized these early speculations, the most "advanced" of which suggested a 30-year transitional period. The first signs of African restlessness did not appear until 1956, and it was only in 1958 that political pressure jolted Belgium out of its secure immobilism. The announcement in January 1959 of far-reaching political reforms came too late to forestall serious riots in the capital.

Mushrooming political parties, vying for recognition, criticized the unilateral character of the reforms and demanded a voice in the formulation of policy changes.

In December 1959, Belgium decided to grant independence within months. The decision was based on several factors, including the fear of businessmen that protracted political unrest might wreck an already ailing economy, the specter of the Algerian war, the deceptively successful example of de Gaulle's rapid decolonization of French tropical Africa, and the belief that an independent Congo would continue to depend heavily on Belgian administrators, technicians, and entrepreneurs. Provisions for the transfer of power and outlines of future political organizations were laid out by the Brussels Round Table Conference (January–February 1960). No single political party, however, won a majority in the preindependence election. Joseph Kasa-Vubu and Patrice Lumumba formed a coalition government and became respectively president and premier when the Congo became an independent republic on June 30, 1960.

6. The Search for National Unity

Within days, the new government's precarious control over the state apparatus was seriously compromised by a series of army mutinies and local disturbances. Seizing on this pretext, Moïse Tshombe, the provincial president of Katanga, backed by certain European elements, seceded from the republic on July 11, while Belgian troops were being dispatched to occupy key positions in the country. President Kasa-Vubu and Premier Lumumba asked the United Nations to help restore order, secure withdrawal of Belgian troops, and reunify the country. Angered by what he considered UN reluctance to accomplish these aims, Lumumba appealed for help to the Soviet Union, but he was dismissed and jailed by Kasa-Vubu on Sept. 5, 1960. The deposed premier fought for control with the backing of several Afro-Asian states, but was murdered in Katanga by his political adversaries in January 1961.

Vice Premier Antoine Gizenga attempted to succeed Lumumba and to set up a national government in Stanleyville (now Kisangani), but actual power in Léopoldville fell into the hands of the military under Joseph Mobutu.

Parliament reconvened under UN protection in July 1961 and on August 2 named Cyrille Adoula to head a cabinet of national reconciliation. Katanga persisted in its secession, however, and it was not until January 1963, after two earlier UN operations had failed, that the break-away province was forcibly reunited with the rest of the country.

The Constitution of 1964. In 1963 the increasingly deadlocked parliament was relieved of its responsibility for drafting a permanent constitution. The task was entrusted to a commission handpicked by President Kasa-Vubu, and the resulting document was declared to have been approved after a somewhat dubious referendum. The new constitution of Aug. 1, 1964, provided for an uneasy division of executive power between the president and the premier—a provision fraught with potential conflict. The structure of the state was made decidedly more federalistic than previously, but the central government retained important powers of intervention in provincial affairs.

Slow and painful reconstruction during 1963 was hampered by economic and administrative breakdown, clashes between radical nationalists and the military-bureaucratic oligarchy, labor unrest, and the ever-impending threat of civil war or secession. The growing disaffection of vast sectors of the rural population led to the outbreak in 1964 of a series of peasant revolts with strong messianic overtones. These were exploited by political radicals such as Christophe Gbenye, Gaston Soumialot, and Pierre Mulele, loosely linked in a group known as the Comité National de Libération (CNL). This committee was backed in turn by a number of African countries, including Egypt, Algeria, Congo (Brazzaville), and Burundi, while the USSR and China competitively intervened.

The Tshombe Administration. Premier Adoula was forced to resign in June 1964 and was replaced by Moïse Tshombe, who returned from self-imposed exile. Tshombe recalled the white mercenary units that had formed the military backbone of the Katanga secession. These forces, backed by substantial U.S. and Belgian military aid, recaptured all rebel-held towns, sealed off the borders, and established at least nominal control over most of the insurgent areas by the end of 1964. Dozens of European civilians and countless thousands of Congolese lost their lives in the fighting.

Tshombe's use of white troops, most of whom were South Africans or veterans of French colonial wars, did not ingratiate him with the political leaders of independent Africa. But with the support of some French-speaking African states, he broke out of his diplomatic isolation and secured the Congo's admission to the French-speaking Organisation Commune Africaine et Malgache (OCAM) in May 1965. Tshombe was unable to establish a nationwide political base, however, and in October 1965 he was removed from office by President Kasa-Vubu, who attempted to replace him with Katanga politician Evariste Kimba. On November 25, in an apparent effort to resolve the ensuing deadlock, Gen. Joseph Mobutu unseated Kasa-Vubu and proclaimed himself president, with fellow officer Léonard Mulamba, as premier, heading a civilian cabinet.

EDOUARD BUSTIN, *Boston University*

7. Contemporary Zaire

In 1966 the centralizing, personalistic character of the new regime began to emerge. The popular Mulamba was dismissed and the post of premier abolished. As chief of state, Gen. Joseph Mobutu (later, Marshal Mobutu Sese Seko) now headed the ministerial council.

Political Centralization. Mobutu reversed the process of territorial fragmentation that had begun in 1960. From 21 provinces in 1965, the number was cut first to 12, then to eight, representing a nearly complete restoration of the colonial divisions. The provinces, once quasi-federal political units with their own governments, became "regions" reduced to administrative subdivisions of the unitary state. Not until 1982, when Mobutu accepted suggestions from external aid donors that he carry out political "liberalization," were the regions given legislative assemblies and a degree of political-administrative autonomy.

In 1967, Mobutu established the Mouvement Populaire de la Révolution (MPR, Popular Revo-

Matadi, Zaire's major seaport, is near the mouth of the Zaire River. The bridge was completed in 1983.

lutionary Movement) and made clear that no other parties would be permitted. The MPR was "the nation politically organized," and all Zairians were members by birth. The high point of centralization came with the 1974 constitution, under which the MPR was made the "sole institution" of society, with all other public bodies mere branches of the party.

All electoral choice took place within the MPR, but the range of choice varied. In the early years, single-party lists were put to the electorate, which had no choice but to vote yes or no. Afterward, multiple candidates were allowed so long as all stood under the MPR label.

The MPR initially espoused a doctrine of nationalism, borrowed from Lumumba's party and others of 1960. By 1971 it was promoting "authenticity," meaning that Zaire should reject foreign cultural influences, such as Christian names. By 1974 the official ideology had metamorphosed into "Mobutism," and spokesmen for the regime were referring to the president as a "Messiah."

Mobutu's style of cabinet government required frequent reshuffles that opened up some new posts and reminded those ministers who were kept on that they could be dismissed next time. In a typical cabinet, all regions of the country were represented, but Mobutu's home region of Equateur was somewhat overrepresented. Often, one or more political exiles were "recuperated" and given a ministerial post.

Coercion was a major tool of governance. In 1986, the U.S. State Department reported that arbitrary arrest and prolonged detention without charges remained common in Zaire, affecting most people who came in contact with the criminal justice system.

Economic Regression. Nationalism implied Zairian control of the economy. By 1967 this objective had led to a clash with Belgium over control of Zaire's major industrial concern, the Union Minière du Haut Katanga (UMHK), which mined copper and cobalt. Eventually, a compromise was reached under which a state-owned mining company, the Générale des Carrières et des Mines (Gécamines) was created. The settlement proved lucrative to UMHK and brought unanticipated costs to Zaire.

In 1973 the government seized some 2,000 economic enterprises owned by foreigners (but not Americans), including plantations and construction and transportation firms, and turned them over to Zairians. The beneficiaries were mainly members of the political elite, with Mobutu himself profiting the most. This "Zairianization" had disastrous consequences, the scope of which became clear within a few months: shortages of goods, tax evasion, even abandonment of businesses. Instead of turning back, Mobutu plunged forward into the "radicalization of the revolution," apparently inspired by the models of China and North Korea. "Radicalization" included the nationalization of trade and the mobilization of agricultural brigades to relieve food shortages. In its application, however, the new measure was transformed from an attack on the Zairianized businesses to an assault on the primarily Belgian-owned industrial sector. The effect was to extend "Zairianization" to virtually all spheres of the economy.

The Debt Crisis. After 1975, Zaire's mounting foreign debt had a major impact on both domestic and foreign policy. By the 1980's the country owed \$5 billion. While this amount was only the eighth-largest in Africa, debt service ab-

The Inga Dam and power project on the lower Zaire is one of Africa's most ambitious development schemes.

sorbed 43% of Zaire's annual budget for 1987, the highest ratio on the continent.

Some causes of the huge debt—for example, a rise in the price of petroleum imports and a fall in the price of copper exports—were beyond Zaire's control. Others were not, notably "Zairianization," "radicalization," the squandering of funds on prestige projects, and the diversion of funds into private overseas bank accounts.

In 1976 the first of a series of economic stabilization programs was adopted, under the guidance of the International Monetary Fund (IMF) and other external forces. Each successive "Mobutu Plan" was supposed to reduce corruption, rationalize and control expenditures, increase tax revenues, limit imports, boost production, improve the transportation infrastructure, eliminate arrears on interest payments, make principal payments on time, and improve financial management and economic planning. Zaire's public and publicly insured debt was rescheduled by the "Paris Club" (diplomats of the leading creditor nations) more than half a dozen times. Private creditors rescheduled their part of the debt in 1980, and numerous meetings of World Bank and Western aid consortia were held to generate further official assistance.

When the first two standby agreements with the IMF yielded meager results, the IMF and the World Bank decided to send in their own teams of experts to run key posts in the Bank of Zaire, the customs office, and the ministries of finance and planning. The head of the Bank of Zaire team, Erwin Blumenthal of West Germany, cut off credit and exchange facilities to firms belonging to members of the political elite and imposed strict foreign-exchange quotas. However, Mobutu and his associates were able to evade many of the restrictions and to wear down Blumenthal and the other experts. After Blumenthal's departure in 1979, the international teams were exceedingly careful to avoid what

one member called the "political hotspots."

In 1981, however, Zaire began to cooperate with the IMF, laying off large numbers of civil servants and teachers. In 1983 it agreed to devalue its currency by 78% and to liberalize the economy. In response, the IMF agreed to a fifth standby arrangement, and the Paris Club agreed to roll over more than \$1 billion of debt, with a maturity of 11 years, against the eight years normally approved for debtor nations. In 1985 and 1987, the Paris Club rescheduled Zaire's debt for 10 years and 15 years respectively, making it clear that the greater leniency being shown to Zaire was by way of a reward for following IMF guidelines.

"Liberalization" of the economy, urged by the IMF and the United States, took different forms in different sectors of the economy. Air Zaire, the inefficient state-owned airline, lost its monopoly and sold off many of its planes. The corrupt minerals marketing board, Sozacom, became a marketing subsidiary of Gécamines. Private firms were licensed to purchase gold and diamonds, in order to provide an alternative to smuggling. This measure apparently was only partially successful, many prospectors concluding that better prices could be obtained by circumventing the middleman.

Although Zaire was following IMF guidelines, compliance was slow to generate greater economic activity within the country, let alone improved living conditions. Even if Zaire's main products should recover their former demand, Zaire would need to put most of the proceeds into debt repayment instead of investing in transportation, education, and health care.

Mobutu, said to be one of the ten richest men in the world, had enriched himself at the expense of the people, whose living standards declined. Zaire had regressed from being a major exporter of agricultural products to an importer of 60% of its food.

AIDS. Like many sub-Saharan countries, Zaire faced disaster in the form of a widespread viral infection that often leads to Acquired Immune Deficiency Syndrome (AIDS). In Africa, where the potentially lethal virus is transmitted primarily through heterosexual intercourse, the educated urban leadership appeared to be stricken in disproportionate numbers, with grave implications for the region's future.

Foreign Relations. Zaire's foreign policy shifted several times after 1965. The economic nationalism of the late 1960's, directed at ex-colonial companies, brought Zaire into conflict with Belgium. During the same period, relations with the United States remained close. Regional initiatives focused on stabilizing relations with neighbors, including several that harbored Zairian exiles.

In the early 1970's, Zaire distanced itself from the United States. It took a leading role among sub-Saharan states in breaking relations with Israel over that country's occupation of Egyptian territory. Mobutu's visit to China and North Korea influenced the rhetoric of his "radicalization" policy.

During the decolonization of Angola, in 1975, the Zairian army intervened on the side of the FNLA and UNITA movements, also backed by the United States and South Africa and briefly by China. But the Zairian forces were routed by the MPLA and its Cuban supporters. Afterward Zaire generally cooperated closely with the United States and its supporters. In 1977 and 1978, Zaire was invaded by exiles based in Angola and had to be rescued by its allies, including the United States, Belgium, France, and Morocco. When Chad's military regime dissolved into a welter of warring factions, Zaire's troops provided support to Chadian President Hissène Habré against former President Goukouni Oueddei, who was backed by Libya.

In 1979, once Egypt and Israel had signed the Camp David agreement and Israel had withdrawn from the Sinai and thus from Africa, Mobutu renewed relations with the Jewish state. Israel began training and directing the Special Presidential Brigade, which guarded the president. Zaire's close relationship with Israel was a factor in Libyan aid to Zairian opposition groups, apparently including the perpetrators of bomb blasts in Kinshasa in 1984.

Zaire's frontiers remained insecure. Zambia's efforts to block smuggling into Zaire led to clashes between their armies. In 1984 and 1985 at Moba, in the Shaba region, Zairian forces battled insurgents of the People's Revolutionary Army, heirs to the rebellion of 1964–1966. The Mobutu government alleged that these attacks, which originated on the eastern side of Lake Tanganyika, were permitted if not actually encouraged by Tanzania and Burundi.

ZAIRES RIVER. See CONGO RIVER.

ZAMA, zā'ma, a town in ancient North Africa where, according to tradition, the Roman army of Scipio Africanus crushed the Carthaginian army of Hannibal in 202 B.C. This crucial battle marked the end of the power of Carthage. By the terms of the peace of 201 B.C., Carthage lost its fleet and thereafter could fight, even in Africa, only with Roman approval. Ancient Zama is generally identified with the present village of Jama, in Tunisia. A village 30 miles (48 km) to the east also claims to be the site.

ZAMBEZI RIVER, zam-bē'zē, in southern Africa, the longest African river draining into the Indian Ocean. The upper Zambezi flows generally southward, the middle Zambezi northeastward, and the lower Zambezi southeastward. The total length of the river is about 2,200 miles (3,520 km) from Zambia to Mozambique and the sea. With its tributaries the Zambezi drains an area of some 500,000 square miles (1.3 million sq km), mostly on the interior African plateau. The river is called the Zambeze in Portuguese.

The Zambezi begins in northwestern Zambia, in a bog near headwaters of the Congo River system. Leaving Zambia, it flows through Angola in a rockbed. It then reenters Zambia, broadening out before passing over Chavuma Falls and crossing the Barotse floodplain. From Ngonye Falls the Zambezi descends through 80 miles (130 km) of rapids to enter the plain of Sesheke. There it forms the boundary between Zambia and the Caprivi Strip extension of Namibia.

After defining the short Zambia-Botswana border the river marks the entire frontier between Zambia and Zimbabwe. First it enters a rocky reach that extends to Victoria Falls, or Mosi-oa-Tunya ("The Smoke That Thunders"). The upper Zambezi ends as it plunges 355 feet (108 meters) in a cloud of spray and a thundering roar into a narrow transverse chasm.

The first section of the middle Zambezi is the Gwembe Valley. For 175 miles (280 km) above Kariba Gorge the valley has been flooded by the reservoir of the Kariba hydroelectric dam, completed at the gorge in 1959. Downstream the river receives two important tributaries from Zambia, the Kafue and the Luangwa. Just after entering Mozambique the Zambezi flows into a second large artificial lake, formed by a hydroelectric dam completed in 1974 at Cabora Bassa Gorge.

From the dam the Zambezi descends from the plateau and flows across the Mozambique Plain, where it receives the Shire River running southward from Lake Nyasa (Lake Malawi). The Zambezi reaches the Indian Ocean through a wide delta that begins 90 miles (145 km) from the coast and covers 25,000 square miles (65,000 sq km). Each of the four main mouths of the river is obstructed by a sandbar at its entrance.

Shallow-draft river vessels can use the Zambezi from the mouth of its Chinde passage through the delta as far inland as Cabora Bassa Dam. Upstream the lakes are similarly navigable, as is the upper Zambezi from Ngonye Falls to Chavuma Falls and into Angola.

The Zambezi has no major port at its outlet and few large towns or cities along its course. The most important riverine urban centers are Tete in Mozambique and Maramba (formerly Livingstone) in Zambia, near Victoria Falls.

ACE WILLIAMS, FROM BLACK STAR

The spectacular Victoria Falls, on the Zambezi River between Zambia and Rhodesia. The Scottish explorer and missionary David Livingstone named the falls in 1855 in honor of the British queen.

ZAMBIA, *zamb'ē-ā*, a landlocked country in Southern Africa. Formerly known as Northern Rhodesia, it is bordered by eight other states. Zambia is named for the Zambezi River, which has an important place in the national economy. The country is rich in minerals and has long depended on exports of copper.

Zambia gained independence under its new name in 1964. Because of its geographic position, it has played a strategic role in the efforts of black Africans to end white control of areas to the south.

1. The Land

Zambia lies to the north of the Zambezi, one of Africa's greatest rivers. The national territory is shaped rather like a butterfly because the Shaba (formerly Katanga) region of Zaire almost cuts Zambia in half, making two large "wings."

Physical Features. Zambia is part of the Southern African uplands. It is mostly a flat or undulating plateau, averaging 3,000 to 5,000 feet (915-1,525 meters) above sea level. To the south the Zambezi has cut a valley averaging only 2,000 feet (610 meters) in elevation. In the northeast the Mafingi Mountains rise to 7,100 feet (2,165 meters). Along the Zaire border elevation averages 4,200 feet (1,280 meters).

Geologically, the Zambian plateau consists of very ancient Precambrian rock. Parts of this rock are highly mineralized. But because the rock generally weathers into shallow, infertile soil, agriculture is limited. Around Lake Mweru are more recent Tertiary rocks, and in the Luangwa Valley, Cretaceous sediment—mostly sandstone—occurs. These areas contain the country's richest soils.

In the north are three lakes: Tanganyika and Mweru (both only partly in Zambian territory) and Bangweulu. They are used locally for transportation and are also important as a source of fish. The Luapula River flows southward from Lake Bangweulu, draining more than 3,800 square miles (9,800 sq km) of swampland, before swinging northward to form part of the border

between Zambia and Zaire. It then enters Lake Mweru, from which its continuation—the Luvua, in Zaire—joins the Lualaba, or Upper Congo.

In the northeast the plateau is cut by the Luangwa River. Formed in the mountains near the Malawi and Tanzania borders, it flows southward through a fault trough. Unfortunately, most of its relatively fertile valley is infested with tsetse flies, which spread both human and animal sleeping sickness and thus limit the use of this area for agriculture. Part of the depression has been set aside as the Luangwa Valley Game Reserve.

Rising on the Zaire border is the Kafue River, which flows southward on the western plateau. Its valley, too, is dominated by the tsetse fly. The valley is the site of Kafue National Park, one of the world's largest game reserves, with some 8,000 square miles (20,700 sq km), on which

INFORMATION HIGHLIGHTS

Area: 290,585 square miles (752,614 sq km).
Boundaries: North, Zaire; northeast, Tanzania; east, Malawi; southeast, Mozambique; south, Zimbabwe, Botswana, and Namibia; west, Angola.
Elevations: Highest—Mafingi Mountains (7,100 feet, or 2,164 meters); lowest—Zambezi River at the Mozambique border (1,200 feet, or 366 meters).
Population: (1980 census) 5,679,808.
Capital and Largest City: Lusaka.
Name of Nationals: Zambians.
Major Languages: English (official) and seven officially recognized African languages.
Major Religious Groups: Christians and followers of traditional African religions.
Monetary Unit: Kwacha (= 100 ngwee).
 For Zambia's flag, see under FLAG, both illustration and text.

hunting is forbidden. Both the Luangwa and the Kafue rivers are tributaries of the Zambezi.

The mighty Zambezi rises in the northwest, near the juncture of the Zambia-Zaire-Angola boundaries, and flows southward in Angola and then in Zambia. It continues as Zambia's border successively with Namibia, Botswana, and Zimbabwe (formerly Southern Rhodesia). Just after it begins to mark the Zimbabwe frontier, it plunges 355 feet (108 meters) off the plateau, creating the spectacular Victoria Falls, or Mosi-oa-Tunya (the "Smoke That Thunders"). Here the river enters a trough and swings eastward in a great arc before reaching the Indian Ocean. Little of the Zambezi can be used for navigation. At Kariba a narrow gorge has been blocked with a dam that reaches a height of 420 feet (128 meters) and provides electricity for most of the country. The lake behind the dam is a source of fish.

Climate. Although Zambia is relatively close to the equator, its climate is moderated by its elevation. There are three seasons. From May to August the country is cool and dry. From September until November it is hot and dry. The wet season begins in December, and the rains last until April, mitigating the heat of the Southern Hemisphere summer.

Rainfall averages 23 inches (585 mm) in the south and rises to more than 50 inches (1,270 mm) in the north. The national average is 32 inches (815 mm), mostly as a result of thunderstorms.

Temperatures vary from 60° to 80°F (16°–27°C) in the cool season and from 80° to 90°F (27°–32°C) in the hot season. Only in the valleys is the heat excessive, especially in October.

2. The Economy

Although Zambia's prosperity is closely linked with the rich copper deposits along its northern border with Zaire, mining employs relatively few people. Most Zambians are traditional farmers, who grow food for their own subsistence and produce little surplus for market.

Mining. Africans for centuries have smelted Zambian copper to make pots and weapons. But

MARC & EVELYNE BERNHEIM, FROM WOODFIN CAMP

Copper bars being loaded at Kitwe for shipment. Zambia's prosperity is based on its rich copper deposits.

it was Cecil Rhodes and his followers late in the 19th century who began large-scale exploitation of the copper deposits that have become the mainstay of the Zambian economy. Fortunes were invested in the Copperbelt before the region began to yield its ore for overseas markets in the 1920's.

Copper and its by-products account for the greater part of the value of Zambian exports. The national income, therefore, is extremely vulnerable to fluctuations in world market prices. Most of the ore is smelted and refined in the Copperbelt before export.

Major lead, zinc, and cobalt deposits are mined and smelted at Kabwe (formerly Broken Hill), south of the Copperbelt. These minerals are exported as well. Smaller amounts of manganese, gold, and limestone are worked in other parts of the country.

Manufacturing and Power. Before independence Zambia had few large manufacturing enterprises outside the mining sector. Half of the nonmineral output consisted of foodstuffs, beer and other beverages, tobacco products, and construction materials. Most of the country's electric power came from the Kariba Dam on the Zambezi River, but the generators were located on the south bank, in Southern Rhodesia, where the white-minority government could cut off Zambia's power. The power problem was solved by the installation of hydroelectric generators on Zambia's side of the dam and by the construction of the Kafue power dam just south of Lusaka.

After 1964 industry quickly expanded and diversified. Major enterprises include textile mill-

The paramount chief of Barotseland travels in the royal barge to the "flood capital" of Limulunga every year.

ing, motor-vehicle assembly, the manufacture of tires and batteries, oil refining (using imported crude), and the production of chemical fertilizers and mining explosives.

Agriculture. Some 7% of Zambia's area is cultivated, while 47% is classified as pasture or grazing land. Most Zambians are subsistence farmers who have to utilize the shallow, highly leached soils of the plateau. They grow maize (corn), beans, and cassava for local consumption. Commercial farms, generally along the railroad that runs from the Zambezi River to the Copperbelt, raise corn and tobacco for export. Irrigation projects along some of the rivers are of increasing importance because they extend the growing season into the dry period.

The tsetse fly prevents livestock raising in more than half the country. Among the people of Zambia, only the Lozi in Barotseland are noted for their herds.

Transportation. Under the administration of the British South Africa Company (1889-1924) and during the subsequent colonial period, a railway system was built to tie Northern and Southern Rhodesia together. At the time of independence, Zambia was largely dependent upon Southern Rhodesian rails. The line carried coal to the Copperbelt from Wankie (now Hwange) in Southern Rhodesia, as well as petroleum products, and took out almost 50% of the copper.

When political relations between Zambia and Southern Rhodesia reached a low point, landlocked Zambia began looking for alternative outlets to the sea. It built an oil pipeline, railroad, and highway to Dar es Salaam, Tanzania, to give Zambia a sure "all black" outlet to the Indian Ocean.

After 1976 this line was not of much use owing to problems on the railroad and massive delays at Dar harbor. A rail route through Angola to the Atlantic Ocean was closed by rebel guerrilla activity in that country. A third railroad cuts through Zaire but is slow and unreliable as well as expensive because it involves transshipment of cargo by river and then by rail again to seaports on the Atlantic. The most convenient route is still the one through former Southern Rhodesia, now Zimbabwe under black-majority rule. But Zimbabwe is also landlocked and depends on rail lines that reach the sea through

Mozambique or South Africa. Mozambique has suffered from chronic political instability, while South African racial policies make Zambia reluctant to use that country's ports, although it has done so.

3. The People

Most Zambians are of Bantu origin, the descendants of earlier migrants. As the Bantus driving southward moved into the area from early in the 1st millennium A.D. to about 1200, they pushed before them the Pygmies and Bushmen whom they found there. Nilotic groups from East Africa arrived early in the 2d millennium. Later, other African groups moved into the area from the south. Today, Zambia has more than 70 ethnic groups classified into eight major societies, speaking some 30 different dialects. English is the official language. Seven other languages are recognized for administrative and educational purposes: Bemba, Kaonde, Lozi, Lunda, Luvale, Nyanja, and Tonga. Many groups are spread across the borders of one or more of Zambia's eight neighbors.

Major Groups. Among the major ethnic groups are the Barotse in the southwest, ruled over by the Lozi people. For several hundred years they have occupied an area on the plains of the Zambezi northwest of Victoria Falls. The river is still their main artery of transportation. The Barotse are fine fishermen. They also own cattle (the area is free of the tsetse fly), plant crops in the dry season, and mine some potash and salt. Thus, Barotseland has an almost self-sufficient economy.

Each year the river floods, and those living at the regular Barotse capital of Mongu move to the "flood capital" of Limulunga. The paramount chief leads the way in a state barge with his drummers setting the pace, and the rest follow in canoes piled high with household goods.

Barotseland was treated as a special administrative entity before Zambia's independence. It then became a Zambian province.

The Bemba people, who live in the north along the Zaire border, are also a major group. Their language is the lingua franca in the Copperbelt because they constitute the bulk of its labor force. They have a highly organized society with centralized rule.

Because of the tsetse fly, the Bemba do not

raise cattle but engage in farming. Because the soil is poor as well, they practice a slash-and-burn agriculture in which they first cut, pile, and then burn the brush. The resulting ash enriches the soil, permitting crops—mostly maize—to grow. After a few years the soil is depleted, and the Bemba move on and repeat the process. It requires about 300 acres (122 hectares) to support a subsistence farm household in this manner. Consequently, the average population density is low—less than 4 persons per square mile (1.5 per sq km).

The Bemba fish in the swamps south of Lake Bangweulu. They grow cassava on the high, drier ground. They sell the fish in the Copperbelt or else trade it for maize with other Bemba people.

Members of the Chewa group, who live along the eastern border, engage primarily in subsistence agriculture. Parts of their area are not bothered by the tsetse fly, and some Chewa keep cattle.

Zambia has small but economically important European and Asian minorities. These groups reside mostly in the cities.

Population Distribution. Zambia as a whole is sparsely populated. The land is capable of supporting only a limited population over most of its area. The country nevertheless has a high birth-rate.

Cities have tended to develop only in the limited areas of rich mineral and agricultural resources. Over 35% of the people live in the Copperbelt, where most of the larger urban centers are found. These include Kitwe, Ndola, Chingola, Mufulira, and Luanshya. To the south is Lusaka, the largest city in the country and the national capital. More than 40% of the population is urban.

Education and Religion. Before independence, primary school cost \$30 per pupil annually and secondary school \$50—sums beyond the means of most Africans. With independence the nation declared free education for all, and school enrollment greatly increased thereafter. However, illiteracy remains a major problem. A modern

university was built at Lusaka. The government allots a sizable portion of its budget to education in an attempt to develop Zambia's most important resource—people.

About half of the people are Christians. Most other Zambians adhere to their traditional religions, whose practices are observed by many Christians as well.

4. History and Government

Human beings have been in the region that is now Zambia for perhaps 200,000 years. Remains of their early works have been found at Kalomo, Kalambo Falls, and south of Lusaka. More recently, the region served as a passage for Bantus migrating southward. Avoiding the hot, insect-infested Zambezi Valley and the desert to the west, they moved to the vicinity of Victoria Falls, where they could cross the river without descending from the plateau.

European Exploration and Colonization. The first Europeans in the area were the Portuguese, who explored a portion of the country in 1514. The Scottish missionary David Livingstone traveled through Barotseland in the 1850's, discovering Victoria Falls in 1855. By the time of his death in 1873, he had explored the entire Zambezi Basin and established missions in the hope of stopping the slave trade carried on by Arabs from the northeast. He helped to inspire British colonization of the area.

In 1889, Cecil Rhodes of the Cape Colony received a royal charter for the British South Africa Company to permit trade and establish a government in the future Northern Rhodesia. Rhodes persuaded Lewanika, paramount chief of Barotseland, to place his kingdom under British protection. Police and troops were stationed throughout the territory.

By 1900 company control had been formally established in the northwest and the northeast. In that year Lewanika signed over trading and mineral rights in his area. The northwest and northeast territories were joined with the protectorate of Barotseland in 1911 to form Northern Rhodesia. The British South Africa Company

A handsome university building in Lusaka. The Zambian government allots a considerable portion of its annual budget to education.

retained control of Northern Rhodesia until 1924, when the crown assumed administrative responsibility. The first capital, Livingstone (now Maramba), near Victoria Falls, was replaced in 1935 by Lusaka. Between 1927 and 1939, four large copper mines were opened, making Northern Rhodesia a major supplier of copper to world markets.

The Nationalist Movement. The need to amalgamate the two Rhodesias was a recurring theme among resident whites from 1915 on, and was intensified in World War II. In September 1953, despite years of vocal African opposition to the plan, Britain proclaimed the Federation of Rhodesia and Nyasaland. Because Africans felt that the federation was only an excuse to prolong white rule, riots and strikes occurred over the years in each of the territories, followed by the declaration of a state of emergency.

African opposition to white rule had given rise to the African National Congress (ANC), a supraethnic party that unified the people living between Lake Tanganyika and the Zambezi River. Harry Nkumbula, ANC president, led the fight against the federation. A more militant group under Kenneth Kaunda broke away as the United National Independence Party (UNIP) and won wide support. Political power in Northern Rhodesia passed for the first time from Europeans to Africans in the 1962 elections, won by an ANC-UNIP coalition. In 1963, ten years after its formation, Britain dissolved the federation. In January 1964 a new election was won by the UNIP. In preparation for national independence a presidential election was held in August. Prime Minister Kaunda ran unopposed. Finally, on Oct. 24, 1964, Northern Rhodesia was proclaimed the independent Republic of Zambia, with Kaunda as its president.

The Republic of Zambia. After independence Zambia was a multiparty state until 1973, when a new constitution abrogated the original 1964 charter. Following elections later that year, the country became a "one-party participatory democracy."

The constitution of 1973 provided for a strong presidency and a single legislative chamber, with the UNIP Central Committee formulating national policy to be executed by the cabinet. All candidates for the National Assembly had to be members of the UNIP and their candidacy approved by the Central Committee. The constitution further provided for a national election every five years, the president and members of the National Assembly being elected by popular mandate. The president was empowered to appoint ten additional members of the Assembly to enhance its geographical or ethnic representation. Subsequent elections renewed the presidency of Kenneth Kaunda, the only candidate.

Kaunda's greatest asset was his ability to appease Zambia's various ethnic, religious, and regional groups. His basic platform was "humanism," in which he condemned human exploitation and stressed cooperation among the people, but not at the expense of the individual. The press remained free to criticize virtually anything except Kaunda's exercise of the presidential authority.

While Kaunda's political policies earned him praise and popularity at home, his economic policies and events over which he had no control bankrupted the nation. After independence, the gross national product (GNP) per capita declined

drastically. The economy remained based on the copper industry, which traditionally accounted for half of the GNP, a third to a half of government revenue, and over nine tenths of foreign-exchange earnings. For the first ten years of independence, copper export earnings climbed; then they fell as the world market price declined. To try and overcome the price decline, a shortage of technicians in the Copperbelt, the long-term effect of oil price increases, and dislocations in transportation, Zambia in 1970 acquired a 51% interest in the two major mining companies. These were merged in 1982 as Zambia Consolidated Copper Mines.

To reduce dependence on copper, the government tried to restructure and diversify the economy. It began a program of state-run industries and periodically nationalized others, eventually operating hotels, transportation services, breweries, mills, and the agricultural wholesale trade. Most such enterprises incurred losses. Food production declined by 25% over ten years. To encourage increased agricultural output, Kaunda announced tax concessions and higher prices for producers, along with improved marketing policies. However, the country did not become self-sufficient in food and continued to spend scarce foreign exchange on food imports.

Foreign aid and loans were intended to promote the development of agriculture, transportation, and manufacturing. But because of government mismanagement and severe drought, Zambia was unable to comply with an austerity program developed by the International Monetary Fund (IMF). In December 1986, Kaunda tried to raise the price of maize by reducing subsidies that had benefited urban dwellers. This measure would have enabled him to pay farmers more and to lower the budget deficit. City dwellers rioted in protest. Four months later, the president sought to raise fuel prices to cut imports and save foreign exchange, but with the same result. In both instances, Kaunda was forced to back down. As a result, Zambia renounced its agreement with the IMF and abandoned its austerity program.

Meanwhile, at the United Nations Conference on the Critical Economic Situation in Africa (May 1986), 24 other African countries had accepted IMF recommendations for economic reforms. These included emphasis on the development of agriculture, transportation, and communications, and improved economic management with less state intervention and greater encouragement of the private sector. The Zambian government, however, was participating substantially in the economy through state-owned or state-controlled companies. For example, the Zambia Industrial and Mining Corporation employed a third of the country's wage earners and accounted for almost half of the gross national product. Only in agriculture, banking, and construction was the private sector of the economy dominant.

The city hall in Zamboanga, a seaport and tourist center of Zamboanga del Sur Province.

Philippine Travel and Tourist Assn.

ZAMBOANGA, sām-bō-āng'gā, municipality, the Philippines, in Zamboanga del Sur Province, on Mindanao, at the southern tip of Zamboanga Peninsula, about 550 miles south of Manila. It is separated by Basilan Strait from Basilan Island, which was once included in the municipality. Zamboanga is the trade center of southwest Mindanao and the area's chief port for both inter-island and international shipping.

Established by the Spanish in 1635 as a stronghold for their campaign against the Moros, Zamboanga was the capital of Mindanao during the entire period of Spanish domination except from 1872 to 1875, when the capital was Cotabato. It was partially destroyed by fire during the revolution of 1897-1898 but was rebuilt and improved during the ensuing United States occupation. When Zamboanga Province was created in 1914, the city became its capital. During World War II, the Japanese fortified the area, which suffered some devastation before it was taken by United States forces in March 1945. It is one of the most colorful cities in the Philippines and attracts numerous tourists. Pop. (1960) 131,411.

ZAMBOANGA DEL NORTE, sām-bō-āng'gā dēl nōr'tā, and **ZAMBOANGA DEL SUR**, sām-bō-āng'gā dēl sōor, provinces, the Philippines, on western Mindanao, including all of Zamboanga Peninsula west of Misamis Occidental Province, together with the adjacent islands. The peninsula is divided longitudinally from northeast to southwest between the two provinces. Zamboanga del Norte occupies the northern and western segment, 2,285 square miles in area, with a long coastline on the Sulu Sea, indented by Dapitan, Sindañgan, and Sibuko bays; the capital is Diplog, in the extreme northeast. Zamboanga del Sur comprises the peninsula's southeastern portion on Sibuguey Bay, Moro Gulf, and Illana Bay, with a deep indentation at Dumanquilas Bay (Moro Gulf). Its area is 4,232 square miles, including the large islands of Basilan (q.v.), off the southern end of the peninsula, and Olutanga. The capital is Pagadian, at the eastern end of the peninsula, on Illana Bay; the municipality of Zamboanga (q.v.), at the southern tip of the peninsula, is also in Zamboanga del Sur.

Except for the fertile coastal plains, the provinces are mountainous, the highest point being **Mount Dapiak** (8,620 feet) in northeastern Zamboanga del Sur. The mountains provide an abundance of timber suitable for shipbuilding and furniture making; gutta-percha and almaciga, a

varnish resin, are exported. Gold is mined, and the coalfield at Malangas, in Zamboanga del Sur, is the largest in the Philippines. Coconuts and abaca are the chief crops. Rice, maize, sweet potatoes, bananas, and rubber are also grown, and carabao, hogs, cattle, and chickens are raised. Fishing is an important economic activity, especially at Zamboanga and Basilan. The people are predominantly Christian, but there are numerous Moros in the coastal and river regions.

History.—The Moros entered the area of the two provinces in the middle of the 15th century, and the Spanish arrived in 1565. Expeditions of Spaniards and Christian Filipinos fought the Moros throughout the 17th century. The area was made a Spanish military district and in 1860 became one of the six districts of Mindanao and Sulu. A rebellion broke out in 1897, and in 1898 revolutionary forces took possession. In 1903, under United States rule, the area became a district of Moro Province, and in 1914 it was reconstituted as Zamboanga Province, with the city of Zamboanga as its capital. It was divided into the present two provinces in the period following World War II. Pop. (1960) Zamboanga del Norte 280,391; Zamboanga del Sur 744,469.

ZAMIA, zā'mē-ə, a genus of gymnosperms in the family Cycadaceae, found in tropical and subtropical America. *Zamia floridana* and *Z. pumila*, growing in Florida, are the only cycads native to the United States. Other species of these cycads are native to the West Indies, Mexico, and Central and South America.

The stem is usually short, bulbous, and partly embedded in the earth. The leaves are pinnately compound, quite rigid, and grow in a spiral cluster at the top of the stem, giving the appearance of a small palm tree. Male and female cones occur on separate plants and are easily distinguished, the male cone being slender, the female cone stout.

The stem contains a starch that is edible if properly washed to remove a poisonous alkaloid. It can be made into a tapiocalike pudding. Florida Indians and natives of the West Indies formerly used it for food; but they are not common enough and do not grow fast enough to be considered food plants of importance any longer.

Plants of this genus make attractive ornamentals as indoor potted plants or for outdoor landscaping where the weather is not too cold. Propagated by seed, they can be transplanted and will survive out of soil for a week or longer without

much harm. After transplanting or severe drought, leaves frequently yellow and die. Six months to a year may pass before new leaves appear.

ROBERT J. RODIN.

ZAMOJSKI, Jan. See ZAMOYSKI, JAN.

ZAMORA, sā-mō'rā, city, Mexico, in the State of Michoacán, on the Mexico City-Guadalajara highway, 95 miles west of Morelia, at an altitude of 1,782 feet. It was founded in 1540 by Viceroy Antonio de Mendoza as a fortified point against the nomad Chichimec Indians, and was named after Zamora, Spain, where most of its first settlers came from. In 1810 the Mexican revolutionary leader Miguel Hidalgo y Costilla accorded Zamora the title of city. It is now an agricultural and small commercial center, famous for its candies, liquors, and native crafts. It has also become well known for its Easter and Corpus Christi festivals. Pop. (1979) 90,000.

IRENE NICHOLSON.

ZAMORA, thā-mō'rā, province, Spain, in the northwestern part of the country, between the provinces of León (north), Valladolid (east), Salamanca (south), and Orense and Portugal (west). The area is 4,089 square miles. The province is divided into distinct regions by the Douro (Duero) River, which bisects it from east to west, and the Esla River, which flows south into the Douro. The western part is mountainous with heights up to 7,000 feet in the Sanabria region on the borders of Portugal and Galicia. Toward the east, the northern sector becomes a rolling plain and blends into the central Castilian plateau; this part is given over almost exclusively to the cultivation of grains. South of the Douro lies the region of Sayago, whose name has become the epitome of rusticity in Spanish literature; it is an extremely rugged terrain, useful for little more than bare subsistence farming and the herding of livestock. A railroad runs north and south through the province. Zamora was long disputed by the kingdoms of León and Castile before their union in the 11th century. Besides the city of Zamora (q.v.), which is the capital, important towns are Benavente and Toro. Pop. (1982 est.) 201,869.

GREGORY RABASSA.

ZAMORA, city, Spain, capital of Zamora Province, situated on the Douro (Duero) River, 40 miles north of Salamanca. It is a market center for the agricultural products of the surrounding countryside. One of the most historic cities in Spain, it was the site of a famous siege in 1072 when the three children of Ferdinand I of Castile and León disputed the city. Numerous ballads deal with this period. The walls constructed earlier as a defense against the Moors still stand in places, and there are many old churches and other buildings. The cathedral was begun in 1151 in Romanesque style; the Church of La Magdalena (c. 1165) is considered one of the best examples of Spanish Romanesque architecture. There is a fine 14th-century bridge of sixteen pointed arches spanning the river. Zamora sided with the *comuneros* against Emperor Charles V in 1520-1521 and was the scene of strife between liberals and conservatives in the 19th century. Pop. (1982 est.) 54,684.

GREGORY RABASSA.

ZAMORA-CHINCHIPE, sā-mō'rā chēn-chē'pā, province, Ecuador, in the southeast corner of the republic, bounded on the east and south by the partially undermarked Peruvian border, on the west by the provinces of Loja and Azuay, and on the north by the Province of Santiago-Morona, from which it is separated by a line south of Gualaquiza. Zamora-Chinchipe and Santiago-Morona were established in 1953 by division of the former Province of Santiago-Zamora. The provincial capital is Zamora, located 35 miles east-southeast of Loja on the Zamora River at the eastern foot of the Cordillera de Zamora, which rises to 9,500 feet. The province is a mountainous and forested area in the foothills of the Andes, drained into the Amazon Basin by the Zamora and Chinchipe rivers. It is inhabited principally by Jívaro Indians. Pop. (1982) 46,691.

ZAMOŚĆ, zā-mōshch, city, Poland, in the Province of Lublin, on the Wieprz River, 45 miles southeast of the city of Lublin. Laid out by Jan Zamoyski in 1579 and modeled on an Italian city, with 16th century fortifications, an arcaded market square, and many fine houses, it is the best-preserved city of Renaissance times in Poland. The town hall and collegiate church are noteworthy. Furniture manufacturing is now the principal industry, although the city also trades in agricultural products. Pop. (1982 est.) 49,100.

ZAMOYSKI, zā-moi'skē, Jan (surname sometimes ZAMOJSKI), Polish statesman: b. Skokowka, Poland, March 19, 1542; d. Zamość, June 3, 1605. He received his education at the universities of Paris, Strasbourg, and Padua. While at Padua, which had the most famous law school of the day, he wrote *De senatu Romano* (1563), his most important work, and was elected rector of the university. Upon his return to Poland in 1565, he was appointed royal archivist and through this position gained a thorough knowledge of the law and politics of his native land. Zamoyski put this knowledge to practical use when he played a decisive role in the election of three successive Polish monarchs—Henry of Valois (1573; Henry III of France), Stephen Báthory (1576), and Sigismund III (1587)—and in the services he rendered to them and his country. As chancellor and hetman (commander in chief) under Báthory, he helped to defeat Ivan IV the Terrible of Russia in a long fierce struggle for the Baltic coast, ending in 1582. Throughout his career he opposed Habsburg candidates for the Polish throne and put an end to the Austrian claim by defeating Archduke Maximilian in the Battle of Byczyna (1588). Although pressed by Emperor Rudolf II and Pope Clement VIII, Zamoyski refused to join the Holy League against the Turks. Instead, he provided for the defense of Poland's southeastern frontier by a policy of armed neutrality toward Turkey, building new fortresses and placing pro-Polish hospodars in Moldavia and Wallachia.

Zamoyski is remembered not only for his political and military achievements, but also for his interest in intellectual and religious affairs. He founded the town of Zamość on his estates in 1579, established a university there (1595), and was instrumental in concluding the Union of Brest (Brześć) in 1596, which brought the Polish Orthodox communicants into the Roman Catholic Church.

CHARLES MORLEY,

Professor of History, the Ohio State University.

ZAMPIERI, Domenico. See DOMENICHINO.

ZAMYATIN, ză-myä'tin, Yevgeni Ivanovich, Russian novelist: b. Lebedyan, Russia, 1884; d. Paris, France, March 2, 1937. By profession he was a naval engineer. His first two novels, *Uyezdnoye* (1911; *A District Tale*) and *Na kulichkakh* (1914; *At the End of the World*), satirical pictures of provincial life, placed him among the leaders of Russian neorealism. During World War I he spent two years in England building ships, and wrote *Ostrovityane* (1917; *The Islanders*), an exposé of British life. After the Russian Revolution his craft and brilliant irony influenced a score of young Soviet writers.

Zamyatin wrote sharp expressionistic stories such as *Peshchera* (1922; Eng. tr., *The Cave*, 1923) and *Mamay* (1922; Eng. tr., 1933) and challenging dramas such as *Ogni sviatogo Dominika* (1923; *The Fires of St. Dominic*), the latter based on the Spanish Inquisition. These, together with his provocative literary essays, made him highly unpopular with the Soviet authorities. Despite persecutions he maintained his independence and never ceased criticizing the new order. Publication abroad of *My* (1922; Eng. tr., *We*, 1924), a satirical preview of a communist society of the 26th century, provoked a violent press campaign against him in Moscow. In 1931 he was compelled to emigrate to France, and his name became taboo in the USSR: even after Stalin's death he was not included among the "rehabilitated" writers. He remains, however, one of the important Russian authors of the 1920's. In the West he is known mainly as the author of *We*, which inspired Aldous Huxley's *Brave New World* (1932) and George Orwell's *Nineteen Eighty-Four* (1949).

MARC SLONIM,
Sarah Lawrence College.

ZANDONAI, dzän-dō-nä'ë, Riccardo, Italian composer: b. Sacco, Trentino, Italy, May 28, 1883; d. Pesaro, June 5, 1944. His musical studies included work under Pietro Mascagni at the Liceo Rossini in Pesaro, from which he was graduated in 1902 and of which he was director from 1939 until his death. His first opera, *Il grillo del focolare*, based on Charles Dickens' *Cricket on the Hearth*, was produced successfully at the Teatro Politeama in Turin in 1908. Although he composed considerable nonoperatic music, his fame depends largely on two of his nine later operas: *Conchita*, based on Pierre Louÿs' *La femme et le pantin* (Milan 1911), the title role of which was sung by Tarquinia Tarquini, whom he married in 1917; and *Francesca da Rimini*, after the tragedy by Gabriele d'Annunzio (Turin 1914), which is still frequently staged in Italy. His mature musical style, reflecting awareness of both Verdi and Puccini, was allied to the realistic style known as *verismo*.

HERBERT WEINSTOCK.

ZANE, zän, Ebenezer, American pioneer: b. near Moorefield, W.Va., Oct. 7, 1747; d. Martin's Ferry, Ohio, Nov. 19, 1812. Sons of a Pennsylvania Quaker, he and his brothers Silas and Jonathan founded (1769) the settlement of Zanesburg, renamed (1806) Wheeling, now one of the major cities of West Virginia. Zanesburg became the Ohio River terminus of the road from Cumberland, Md., which was used by many settlers in Ohio. A Virginia militia colonel during

the American Revolution, Ebenezer helped repel British and Indian attacks on Fort Henry at Zanesburg. During one of these engagements (1782) his sister Betty became a heroine when she retrieved a keg of gunpowder under heavy Indian fire. In 1796, on condition that he blaze a road from Zanesburg to Maysville, Ky., before Jan. 1, 1797, Congress offered him three lots in the Ohio territory, stipulating, however, that he pay United States bounty warrants, provide roads and ferries, and survey the tracts at his own expense. He fulfilled all the conditions, and the important trail that he blazed became known as Zane's Trace. On one of the tracts that Congress granted him, Zanesville, Ohio, was platted in 1797, and Lancaster on another in 1800.

ZANELLA, dzä-něl'lä, Giacomo, Italian poet: b. Chiampo, Vicenza Province, Italy, Sept. 9, 1820; d. near Vicenza, May 17, 1888. He became professor of philosophy and Italian literature at Vicenza Seminary after being ordained a priest in 1843. In 1853 he was suspended from his post for sympathizing with the ideas of the Revolution of 1848. He then held teaching posts at Venice and at Padua, where he was made professor of Italian literature in 1866. From 1871 to 1872 he was rector of the university. A nervous breakdown followed his mother's death, and he retired to a villa near Vicenza in 1876.

Zanella's first collection of poetry, *Versi* (1868), earned him immediate acclaim, and he continues to be recognized as a representative mid-19th century poet. *La religione, La veglia, Milton e Galileo*, and *L'evoluzione* are among his worthiest and most genuine poems; *Sopra una conchiglia fossile* (Fossil Shell) is his most celebrated lyric; all reveal the thematic desire to bring the spiritual need for religious faith into harmony with the new doctrine of evolution. As a translator of Thomas Gray, Shelley, and Henry Wadsworth Longfellow, he was—like Alfred Tennyson—capable of expressing anew the rightness of social, moral, and religious preoccupation in a calm spirit of reconciliation. Other works include *Scritti vari* (1877), *Vita di A. Palladio* (1880), *Paralleli letterari* (1885), and *Poesie* (collected 1928).

EUGENIO VILICAÑA.

ZANESVILLE, zānz'vīl, city, Ohio, seat of Muskingum County, 52 miles east of Columbus, on the Muskingum River at the mouth of the Licking. Major products include ceramic tiles, transformers, sheet steel, batteries, radiators, cement, hydraulic and farm machinery, packaged meats and dairy products, glass, stoneware, and art pottery. A distinctive feature is the Y Bridge, the stem of which is an east-west span across the Muskingum to the mouth of the Licking, where it forks, one span going to the north and the other to the south side of the Licking. There is an airport. The city's name honors Ebenezer Zane (q.v.), owner of the military bounty land parcel on which the city had its beginning in 1797. From 1810 to 1812 it was the capital of Ohio. It was incorporated in 1814. The novelist Zane Grey and the architect Cass Gilbert were born here. A council-manager form of government was adopted in 1958. Population: 26,778.

JAMES H. PICKERING.

ZANGWILL, zāng'gwīl, Israel, English author: b. London, England, Feb. 14, 1864; d. Midhurst,

Sussex, Aug. 1, 1926. The son of a poor Russian immigrant, he was educated at the Jews' Free School and London University, and became the literary interpreter of Whitechapel, the London ghetto at the close of the 19th century. His books *Children of the Ghetto* (1892), *Ghetto Tragedies* (1893), *The King of Schnorrers* (1894), *Dreamers of the Ghetto* (1898), and *Ghetto Comedies* (1907) gained him the reputation of being Anglo-Jewry's greatest writer. Zangwill retold in English many tales known to generations of Yiddish-speaking Jews in eastern Europe and overheard by him in London's immigrant quarters. His marriage to a non-Jew in 1903 led him to write *The Melting Pot*, in which he defended intermarriage between persons of different faiths; the title of this play, produced in New York City in 1908, became a synonym for the Americanization of immigrants. The drama proclaimed that America was God's crucible, into which was to be hurled the entire heritage of the Old World past—its dreams and sacrifices, traditions and superstitions—and out of which a new product would emerge, the new man and the new culture that would be far better than the old. Other Zangwill plays were less successful. They range from a light comedy based on his earlier novel *Merely Mary Ann* (1893) and the pacifist drama *The War God* (1911), to his last play, *We Moderns* (1923).

Zangwill was the first English disciple of Theodor Herzl, father of Zionism. After Herzl's death in 1904, however, he broke away from the Zionists' concentration on the return of Jews to their historic homeland in Palestine, and in 1905 founded the Jewish Territorial Organization for the settlement of homeless and persecuted Jews in autonomous territories wherever available. He was president of this movement until its dissolution in 1925. His essays on Jewish themes were collected in *The Voice of Jerusalem* (1920). His provocative address to the American Jewish Congress, *Watchman, What of the Night?* (1923), aroused fierce controversy. He also translated Hebrew liturgical hymns into English and made English translations of the Hebrew poems of the medieval Sephardic lyricist Solomon ben Judah ibn-Gabriel.

SOL LIPTZIN,
Professor of Germanic and Slavic Languages, City
College of the City University of New York.

ZANTE, zān'tē (Gr. ZAKYNTHOS; Lat. ZACYNTHUS), island, Greece, one of the Ionian Islands, in the Ionian Sea, 12 miles northwest of the Peloponnese across Zante Strait, and 10 miles south of the island of Cephalonia. It is 21 miles long, and up to 10 miles wide, with a 58-mile coastline indented by Laganas, a deep bay, at its southern extremity. The area is 168 square miles. The capital is Zante, situated on the site of the ancient Zacynthus, which has a good harbor on the east coast.

The west of Zante is rugged and mountainous, rising to elevations of 2,480 feet. A fertile alluvial plain covers the eastern half of the island; rich in vineyards, olive groves, and orchards, it provides the principal agricultural exports: currants, olive oil, and citrus fruits. Other crops are negligible, and goats are the only livestock. Gypsum deposits, sulfur springs, and mineral pitch are found, and petroleum has been detected. There is a small industrial production of soap, face powder, olive-pit oil, earthenware,

and *mantolata* (candy). Ninety percent of the inhabitants live in the eastern half of the island, and almost 30 percent in the capital. Earthquakes have been recorded since 1554, with severely destructive shocks in 1893 and 1953.

According to legend, Zante was settled by Zacynthus, son of the Arcadian king Dardanus, and later belonged to Ulysses (Odysseus), king of Ithaca. It served Athens as a naval base in the Peloponnesian War (late 5th century B.C.) and was taken by Macedon under Philip V, who surrendered it to Rome in 191 B.C. The island was occupied by the Normans in the 11th century A.D. and became a Venetian possession in the 15th century. For its subsequent history, see IONIAN ISLANDS. Pop. (1981) 30,014.

ZANTHOXYLUM, zān-thōk'sə-ləm, a genus of erect or climbing shrubs or trees of the family Rutaceae, closely related to the orange genus *Citrus*, often with prickly branches. The leaves are pinnately compound, sometimes reduced to three or, rarely, to one leaflet. The flowers are small, frequently dioecious, in axillary or terminal cymes or panicles, and are from three to five parted. The fruits, which are quite ornamental in several species, split in two at maturity, exposing one or two shining black seeds. *Zanthoxylum* is a large genus (150 species), found in both the Eastern and Western hemispheres, especially in their warmer parts, but extending as far north as Minnesota, Massachusetts, and Ontario in North America.

The commonest and hardest species of the northern United States is *Z. americanum*, a shrub or small tree with odd-pinnate leaves and twigs that are generally prickly; hence the common name, prickly ash. The cymose inflorescences are axillary and sessile. The greenish white flowers have no calyx. The capsulate fruits are black and ellipsoidal. It is sometimes called toothache tree because the Indians and early settlers used its hot and acrid bark and that of *Z. clavaherulis* for aching teeth; extracts of these temperate North American species, applied externally to the gums, are powerful diaphoretics.

The West Indian species are called yellowwood; *Z. caribaeum* is a tree 20 to 50 feet high whose prickly young stems are made into walking sticks, while the wood is used for inlaying and for furniture; *Z. cribrosum* is the satinwood of the West Indies which, when first cut, has the odor of true satinwood; *Z. fagara* is a small tree common in the same region and in tropical America generally, producing a hard, heavy, reddish brown wood known as colima, ironwood, or wild lime. Still another species is *Z. emarginatum*, a shrub with coriaceous foliage, exported under the name of rosewood but called licca tree or lignumvorum locally.

Some species are so aromatic and pungent that in the countries where they grow they are popularly called peppers, especially *Z. piperitum* (Japan or China pepper), which is regarded as an antidote for poison. *Z. rhetsa*, an Indian species, has small yellow flowers and smooth round berries which, when unripe, taste like the skin of a fresh orange. Its fruits, and the seeds and bark of *Z. alatum*, which grows near the base of the Himalayas, as well as those of *Z. budrunga*, also Indian, are given as aromatic tonics in fever, diarrhea, dysentery, and cholera; they are used as a condiment in India and as a fish poison, and the small branches are employed to make

toothbrushes. The seeds of *Z. budrunga* are as fragrant as lemon peel. The powdered bark of *Z. hiemale* is given in Brazil for earache.

ROBERT L. HULBARY,
Professor of Botany, State University of Iowa.

ZANUCK, zān'ək, Darryl F(rancis), American motion picture producer: b. Wahoo, Nebr., Sept. 5, 1902; d. Palm Springs, Calif., Dec. 22, 1979. After Army service (in spite of his extreme youth) in France during World War I, he began to write, edit, and finally produce for Warner Bros. Pictures, Inc., and was made chief executive in charge of production in 1931. In 1933, with Joseph M. Schenck, he organized Twentieth Century Pictures, which two years later merged with Fox as the Twentieth Century-Fox Film Corporation, with Zanuck as vice president in charge of production. Zanuck served in the Army again early in World War II, making training and documentary films, and in 1943 returned to his company. In 1956 he became an independent producer, releasing his films through Twentieth Century-Fox, and in 1962 he was elected president of the company. Recognized as one of Hollywood's most brilliant producers, he developed many new star performers and pioneered in the use of CinemaScope (q.v.). He received the Irving G. Thalberg Memorial Trophy in 1937, 1944, and 1950. Among his films are *Public Enemy* (1931); *The House of Rothschild* (1934); *Grapes of Wrath* (1940); *Anna and the King of Siam* (1946); *Gentleman's Agreement* (1947); *Pinky* (1949); *The Robe* (1953); *The Snows of Kilimanjaro* (1953); *The Man in the Gray Flannel Suit* (1956); and *The Longest Day* (1962).

ZANZIBAR, zān'zə-bār, is an island portion of the United Republic of Tanzania, a union of Tanganyika and Zanzibar. It merged with the African mainland country on April 27, 1964, only a few months after Zanzibar had itself become an independent nation. Zanzibar comprises the small islands of Zanzibar (640 square miles) and Pemba (380 square miles), both lying in the Indian Ocean off east Africa. Their combined area is half that of the state of Delaware.

Physical Features.—The island of Zanzibar is situated at 5°30' south latitude, 39°30' east longitude, approximately 22.5 miles across the Zanzibar Channel from the old Tanganyika port city of Bagamoyo. Nearly 53 miles long and 24 miles wide, it is the largest coral island on the African coast. It is gently rolling land, with Masingini Ridge (390 feet) as its highest point. Numerous bays, reefs, and islets are found along the western coast, while the eastern side is much more regular, with Chwaka Bay the only significant coastal indentation. A fringing reef guards the eastern shore for nearly 50 miles.

The smaller island of Pemba, approximately 35 miles northeast of Zanzibar and 40 miles from the Tanganyika shore, is 42 miles long and 14 miles wide. Also a coral island, it has an irregular coastline on the west and a straight one, accompanied by a fringing reef, on the east. Although its elevation does not exceed 300 feet, Pemba is much more dissected than Zanzibar.

Both islands experience a tropical monsoon climate with two marked rainfall and temperature periods. The two maximums of rainfall are the long rains in March, April, and May, and the short rains in November and December. The other months are dry, although they are rarely

Location map of Zanzibar, with principal towns.

without some precipitation. The annual rainfall approximates 60 inches on Zanzibar and 80 inches on Pemba. Although the seasonal temperature range for the year is small (only 6° F. at the town of Zanzibar), there is a marked difference in sensible temperatures brought on by a shift in monsoon winds. At the end of the long rains the southwestern monsoon winds bring fresh, relatively dry air into the islands from the South African landmass; temperatures average as low as 76° F. during July and August. The beginning of the short rains brings a shift of winds from the northeast. These antimonsoon winds, having blown out of Asia, sweep over the Indian Ocean and arrive below the equator both hot and moist. Average temperatures rise to between 82° and 85° F. by February and, joined with the high humidity, make a most enervating climate. This tropical, moist climate results in an abundance of indigenous and cultivated vegetation.

The People.—The combined population of Zanzibar and Pemba was about 475,000 according to the 1978 census—an increase of more than 100,000 over the 1967 census. The racial composition of the islands is heterogeneous. The major groups are Africans from the mainland, Arabs, and Asians. Although the Africans comprise about half the population, economic and political power rests mainly with the Arabs and Asians.

The Africans, mainly Bantus in origin, are divided into two distinct social groups: the Shirazis who are descendants of the original inhabitants of Zanzibar and Pemba with some claiming to be descended from Persian immigrants, and the mainland Africans, who are descendants of peoples from mainland East and Central Africa or more recent settlers from these areas. The Shirazis comprise approximately 61 percent of the total population of Zanzibar and Pemba; the mainland-African group, 21 percent. Economically, the Shirazis are predominantly fishermen or farmers on private or community lands, while the mainland Africans are town laborers or squatters on plantations. Both African groups are almost entirely Muslim.

With a population of about 69,000, Zanzibar city on Zanzibar Island is the only major settle-

ment on either island. The high population density of both islands is indicative of the fertile soils and intensive cultivation. These conditions are manifest on Pemba and in the central and western sections of Zanzibar, where there are heavy demands for labor on the large Arab- and Indian-owned clove and coconut plantations. High rural densities are also apparent on many small African farms growing fruit and vegetables as well as cloves.

Economy.—Zanzibar and Pemba account for most of the world's production of cloves. It is estimated that 80,000 acres with 4 million bearing trees are under cloves on the two islands. Unfortunately disease, as yet unconquered, is threatening disaster to the clove plantations on Zanzibar, so that Pemba accounts for about two thirds of the total annual production of 15,000 tons of dried buds. Nearly 76 percent of the value of the country's exports comes from cloves and clove products.

The coconut is the other cultivated agricultural product of note. Although older in the islands' economy than cloves, the production of coconuts is much less important. Products such as copra, coconut oil, and oil cake account for only 17 percent of the exports.

Cattle are numerous on both islands. Industry is limited, much of it being concerned with the processing of clove and coconut products. Shipping remains an important activity, however. Though by no means as important as it was 100 years ago, the old port of Zanzibar accommodates 3 million tons of shipping annually, not including 3,000 dhows.

History.—Early Centuries.—The monsoon winds have played an extensive role in the history of Zanzibar, as they have for much of the East African coast. Blowing rather constantly for six months from one direction and then shifting to blow for six months from the opposite direction, they permitted the merchant sailors of the Arabian Peninsula, Persian Gulf, and India to sail their dhows to East Africa to trade and, when the wind shifted, to return home. This ancient commerce has been carried on for well over 2,000 years. As a result, probably no other African area except Egypt can boast so long a history. The first written record of the area occurs in the Greek treatise *Periplus of the Erythraean Sea* (1st century A.D.) with an account of the island of "Menuthias," probably Pemba.

Paradoxically, little in the way of permanent settlement was carried out by the early traders. The earliest permanent inhabitants of the islands were Bantu migrants from the mainland, who settled there during the early part of the Christian era. At this time the Arabs referred to the East African area as "Zanjabār" (Land of the Blacks), from which the name Zanzibar was derived many centuries later.

Non-African settlement took place on the islands after the rise of Islam in the 7th century. War and unrest in Arabia and Persia stimulated migrations along the East African coast. In many cases settlements occurred on small offshore islands that afforded protection against the hostile Bantu. Because of their distance from the coast, Zanzibar and Pemba were slower to be settled; however, Persians arrived permanently on Zanzibar in 701, and Persians and Arabs on Pemba in 703.

Although trading centers and plantations were established, little of Zanzibar's history is re-

corded until the coming of the Portuguese in the 15th century. In 1503 Zanzibar came under Portuguese domination. Primarily concerned with establishing forts and revitalizing stations for their shipping in the East Indies trade, however, the Portuguese did little to develop tropical plantation agriculture, and aside from establishing the city of Zanzibar, their contribution to the development of either Zanzibar or Pemba was not great. The Arabs remained on the islands to continue their agriculture and expand their trade in slaves, ivory, and spices.

Arab and British Rule.—In 1698 the Omani Arabs drove the Portuguese from Pemba and in 1710 garrisoned their troops on Zanzibar. From that time until the late 19th century the Arabs held firm control, and Zanzibar attained its greatest historical importance. In 1832 Sa'id ibn-Sultan, the ruler of Oman, moved his capital from Muscat (Masqat) to Zanzibar; with the result that Zanzibar became the principal commercial and political center of East Africa. Its location made it ideal for outfitting slave-raiding caravans for their journey into the interior, and it became the great slave market for the returning raiders, importing 10,000 to 15,000 slaves annually during the early 1800's, most of them reexported to the Arab and Indian world. Zanzibar was also important as an outfitting post for many of the great East African explorers, such as John Hanning Speke, Sir Richard Francis Burton, and Sir Henry Morton Stanley.

In 1861 Zanzibar became independent of Oman. Pressure from the British gradually strangled the slave trade, and in 1873 the sultan ordered the great slave markets closed. However, Zanzibar's commercial position was not greatly weakened; so long as transportation facilities on the mainland were poor, the island retained a hold on the trading caravans and continued as a significant entrepôt center. Furthermore, both islands had developed into great spice producers as a result of the edict laid down by Sa'id ibn-Sultan providing that all plantation owners must plant three clove seedlings for every coconut palm or forfeit their plantations.

The sultan lost most of his claims to the African mainland in the power struggle between Britain and Germany in the latter part of the 19th century, and in 1890 the British proclaimed a protectorate over the dominions.

The protectorate remained in effect for 73 years. After 1955, constitutional reforms increased the representation of Arab, African, and Indian communities in the government. Political parties developed, but on a racial basis, and interracial hatred was generated between Arabs and Africans. In elections of 1961 and 1963, the Afro-Shirazi Party (Bantu and Bantu-Persian) won a slight advantage over the Zanzibar Nationalist Party (Arab). It was unable to form a government, however, and the Nationalists gained control of the legislature through coalition with the Zanzibar and Pemba People's Party (a break-away Shirazi group).

Independence.—Zanzibar attained internal self-government in June 1963 and full independence on Dec. 10, 1963, as a constitutional monarchy under Sultan Seyyid Jamshid bin Abdulla. On Jan. 12, 1964, the Arab-dominated government was overthrown in an armed uprising led by Afro-Shirazis and a leftist group known as the Ummas. Zanzibar was proclaimed a republic with Abeid Karume, Afro-Shirazi leader, as president.

Although Karume was regarded as pro-Western, the "People's Republic of Zanzibar" appeared to be dominated by communists, notably Abdul Rahman Mohammed, a key cabinet minister. On April 27, 1964, Zanzibar was merged into the United Republic of Tanganyika and Zanzibar (renamed Tanzania) in an apparent attempt to keep Zanzibar out of the communist camp. In this union, Karume became vice president under President Julius K. Nyerere of Tanganyika.

H., *Zanzibar: Its History and Its People* (1931; reprint, Biblio. Dist. 1967); Middleton, John, and Campbell, Jane, *Zanzibar: Its Society and Politics* (1965; reprint, Greenwood Press 1985).

ZANZIBAR, city, Zanzibar, is situated on the west coast of Zanzibar Island, 45 miles north of Dar es Salaam, Tanganyika. It is the commercial center of Zanzibar. The world's principal exporter of cloves, Zanzibar also ships citrus fruits, chilies, mangrove bark, and copra. Clove-oil distilling, soapmaking, coconut-oil pressing, and handicrafts are local industries.

Zanzibar was founded in the 1500's as a center for the East African trade. It gained prominence in 1832 when the Omani capital was transferred here. With the rise of the competing ports of Mombasa (in Kenya) and Dar es Salaam, its political and commercial importance declined. The inner town, Ngambo, is mainly the African quarter. Stone Town, facing Zanzibar Channel, is largely the Arab and Indian quarter. Pop. (1958) 57,923.

ZAPATA, sä-pä'tä, **Emiliano**, Mexican general and agrarian reformer: b. San Miguel Anenecuilco, Ayala, Morelos State, Mexico, Aug. 8, 1883; d. Chinameca, Ayala, April 10, 1919. An uneducated peasant, of Indian blood, he joined Francisco Madero in March 1911 in the movement

1914, forcing Carranza to flee. Zapata was soon compelled to withdraw to Tlaltizapán, south of Cuernavaca, in his native state of Morelos, where he continued fighting with his peasant army under the slogan of "land, liberty, and death to the hacendados [landowners]." Zapata had difficulty in controlling his undisciplined followers, who pillaged the villages between Mexico City and Cuernavaca, and he has been called variously the apostle of agrarian reform and the Attila of the south. He received strong support from his brother Eufemio, who died in a brawl in 1917. He himself was assassinated by Col. Jesus Guajardo, who pretended to be a peasant in Zapata's revolutionary army in order to kill him. See also MEXICO—27. *Modern Mexico.*

IRENE NICHOLSON.

ZÁPOLYA, zá'pō-lyō, or **SZÁPOLYAI**, só'pō-lyoi, a leading family of the Hungarian nobility, probably of Slavic origin, which provided two kings of Hungary during the 16th century.

STEPHEN ZÁPOLYA: b. ?1448; d. 1499. An able lieutenant of King Matthias Corvinus of Hungary, he waged successful warfare against the Turks and contributed notably to the Hungarian conquest of Vienna in 1485.

JOHN ZÁPOLYA: b. Spišské Podhradie (Szepesvárálja), Slovakia, 1487; d. Sebes (Szászsebes), Transylvania, July 22, 1540. The son of Stephen, he was voivode (governor) of Transylvania in 1511–1526. In 1514 he ruthlessly crushed the widespread revolt of oppressed serfs led by György Dózsa, and when the boy king Louis II came to the Hungarian throne in 1516, Zápolya served as regent. After Hungary turned down a Turkish demand for tribute, Turkish armies invaded the country. At the Battle of Mohács (Aug. 29, 1526) the greatly outnumbered Hungarians were routed, and Louis II was drowned while trying to escape; Zápolya kept his own forces aloof from the conflict. Fierce factionalism then reappeared within the Hungarian aristocracy over the question of a new king. A staunchly nationalist group, which wanted no ruler from a foreign country, above all no Habsburg from Austria, chose Zápolya as King John I. Slightly more than a month later, on Dec. 16, 1526, the Habsburg or court party awarded the crown to Archduke Ferdinand of Austria (later Emperor Ferdinand I).

Civil war immediately broke out between partisans of the rival claimants to the throne. In 1527 King John was forced to take refuge in Poland. As his chief counselor he picked a statesmanlike Pauline monk, Juraj Utješević (George Martinuzzi, or Frater Georgius), who was bent on reuniting historic Hungary. To that end, in 1528 an unprecedented alliance was negotiated with the Turks, who carried out several campaigns on behalf of King John. In 1538 the childless John executed a diplomatic somersault and arranged the Peace of Nagyvárád (Grosswardein) with Ferdinand, whereby the latter would become sole king of Hungary upon John's death. The birth of a son to John robbed the settlement of all value.

JOHN SIGISMUND ZÁPOLYA: b. 1540; d. 1571. Son of John Zápolya, he was elected king of Hungary as John II by the supporters of his father on the latter's death. Ferdinand of Austria once more appealed to the sword. Recognizing the infant king as the legitimate sovereign, the Turks moved their armies into Hungary again and occu-

Emiliano Zapata

The Bettmann Archive

to liberate Mexico from the dictatorship of Porfirio Díaz. By November of the same year he was refusing to acknowledge Madero as president and had formulated his own Plan de Ayala for agrarian reform. When, after Madero's execution by counterrevolutionaries in 1913, Venustiano Carranza set up a new revolutionary government, Zapata repudiated his leadership also, joined forces with Francisco (Pancho) Villa, and entered Mexico City triumphantly with Villa in

pied (1541) the capital, Buda, and the rich farmlands to the east. John Sigismund had to be content with authority over Transylvania and the adjoining counties. He was succeeded, on his death, by Stephen Báthory.

ARTHUR J. MAY,
Professor of History, University of Rochester.

ZAPOROZHE, zá-pə-rozh'yə, oblast, USSR, in the Ukrainian SSR, between the Dnieper River and the Sea of Azov, with Dnepropetrovsk Oblast to the north and Kherson Oblast to the west. Formed in 1939, it has an area of about 10,000 square miles. The growing season in the oblast is 210 to 220 days, the annual precipitation averages 14 inches, and the fertile dark brown and black soils yield good harvests of winter wheat, sunflowers, melons, vegetables, potatoes, and corn for livestock. The Dnieper Dam and power station is a source of power for the growing industries of the oblast. Pop. (1983) 2,008,000.

W. A. DOUGLAS JACKSON.

ZAPOROZHE, city, USSR, capital of Zaporozhe Oblast in the Ukrainian SSR, 40 miles south of Dnepropetrovsk on the left bank of the Dnieper River before it bends to the southwest. A rapidly growing industrial city and an important river port, Zaporozhe lies on the main trunk line from Moscow to Sevastopol and has rail connections with Krivoi Rog and Donetsk (formerly Stalino) in the Donetsk Basin. Before the revolution it was noted for its large grain-handling facilities. Its modern industrial development dates from the early 1930's. A dam, built in 1927-1932, made complete navigation possible by submerging the rapids and raising the level of the river 121 feet. On the right bank is a large hydroelectric installation, Dneproges, with a capacity of 550,000 kilowatts (the greatest in the world for some years). The city is also noted for its metallurgical plant (Zaporozhstal) and electric furnaces (Dneprospetsstal), producing high quality steels. In addition, there are factories turning out aluminum, chemicals, and machinery. Although much damage was done to the city, its factories, and the hydroelectric plant during World War II, this was repaired by 1950.

Zaporozhe (known as Aleksandrovsk until 1921) or rather the islands in the river below the rapids, was a Cossack stronghold in the 16th century. The fortress (*sech*) served as a base for operations against the Turks, Crimean Tatars, and Poles; in the middle 1950's, however, the construction of a dam downstream at Kakhovka obliterated much of this historic setting. The city was not founded until 1770, and by 1910 the population was only 38,000. Pop. (1983) 835,000.

W. A. DOUGLAS JACKSON,
Professor of Geography

ZAPOTEC INDIANS, zá-pə-ték, an Indian people of the State of Oaxaca, in southern Mexico. Their language is related to Mixtec and more distantly to Otomí. Zapotec (*Zapoteca*) is the Aztec designation for this people; their own ancient name seems to have been *benezaa* or *vinizaa* (people of the clouds). This, as well as linguistic affinity, points to a common origin with their western neighbors, the Mixtec. They now identify themselves by different local variants of a term meaning "people who speak Zapotec."

Archaeologists have traced Zapotec prehistory

in central Oaxaca back to the 1st millennium B.C. The period of greatest splendor of the hilltop metropolis of Monte Albán, culminating in approximately 500 A.D., seems definitely creditable to this people. Later Zapotec pre-Columbian capitals were Zaachila and Mitla. See MEXICO—18. *Architecture* (Valley of Oaxaca); OAXACA (city)—*Archaeology*.

The territory now occupied by Zapotec communities includes a north-south band across the center of Oaxaca State and the southern section of the Isthmus of Tehuantepec to the east. Four main divisions are recognized: (1) the northern mountains (main towns: Ixtlán, Villa Alta, and Choapan); (2) the central valley of Oaxaca (Tlaxiaco, Centro, Etla, Ocotlán, Zimatlán, Ejutla); (3) the southern range (Miahuatlan); (4) the isthmus (Tehuantepec and Juchitán). In the early 1970's the Zapotec numbered more than 300,000 people.

Modern Zapotec culture is far from uniform. The differences are due to diversity of habitat, influence of neighboring Indian groups, and varying rates of colonial Spanish and modern Mexican acculturation. The nation includes closed traditionalist communities as well as townspeople, the bond between the distinct regional and cultural groupings being common language and group consciousness.

ZARA. See ZADAR.

ZARAGOZA. See SARAGOSSA.

ZARATE, zá-rä-tä, city, Argentina, in Buenos Aires Province, on the Paraná de las Palmas River, 50 miles northwest of Buenos Aires. It is an important river port in a fertile agricultural and dairying region. Industries include meat-packing and paper milling. A railroad ferry connects it with the city of Ibicuy. Zárate was founded in 1801. It was called General José F. Urriburu from 1930 to the end of World War II. Pop. (1980) 65,504.

ZARATHUSTRA. See ZOROASTER.

ZARATITE, zá-rä-tīt, a hydrous basic carbonate of nickel, often called emerald nickel, $\text{Ni}_3(\text{CO}_3)(\text{OH})_4 \cdot 4\text{H}_2\text{O}$. It is an emerald green incrustation, usually on chromite.

ZARLINO, dzär-lé'nō, **Gioseffo** (often called **ZARLINUS CLODIENSIS**), Italian musical theorist and composer: b. Chioggia, Italy, March 22, 1517; d. Venice, Feb. 14, 1590. A Franciscan monk, he studied music at the singing school of Adrian Willaert in Venice from 1541. In 1556 he was appointed maestro di cappella at St. Mark's in Venice, and he became a noted pedagogue. Few of his compositions survive. His signal importance in the history of musical theory derives from his *Istitutioni harmoniche*, published in four parts at Venice in 1558 and subsequently reissued; his *Dimostrazioni harmoniche*, a series of dialogues issued in 1571; and his *Sopplimenti musicali* (1588), a polemic reply to sharp attacks on his theories by his former pupil Vincenzo Galilei, father of the great astronomer, Galileo Galilei. Zarlino pioneered in urging a salient role for the immediate predecessor of the modern major scale, in the evolution of the manners of analyzing intervals and triads which became prevalent in the

18th and 19th centuries, and in urging the adoption of equal temperament, notably for tuning lutes.

HERBERT WEINSTOCK
Coauthor of "Men of Music"

ZARZUELA, thär-thwä'lä, a musical stage piece, Spanish in origin and development, in which music and song alternate with dialogue. The name is derived from the palace of La Zarzuela, a royal country seat near Madrid, where the Spanish royal family attended festivals featuring this type of staged entertainment during the 17th century.

Modern zarzuelas are of two types: the *zarzuela grande* (grand zarzuela), usually serious and dramatic in character, in two or three acts; and the *zarzuelita* (little zarzuela), usually in one act, and comic in nature. The plots may be tragic, fantastic, melodramatic, or a mixture of these, often satirizing some literary work, opera, political situation, or other matter of the moment. The form is not definite, the singing is free and imaginative, and improvisation is employed. Extemporaneous comments and jokes may pass freely between the artists or even between the performers and the audience. Some features of the Viennese operetta and even of American jazz have been employed in recent zarzuelas.

Many of the best-known writers and composers of Spain have contributed to the thousands of zarzuelas that have been produced. Some pieces have been presented only once, while others, more stable in nature, have been presented numerous times, even at the Royal Opera House in Madrid. Some of the best-known zarzuelas were composed in the 19th century, notably *La Gran Vía* (1886) by Federico Chueca (1848–1908) and Joaquín Valverde (1846–1910), *El Duo de la Africana* (1893) by Fernández Caballero (1835–1906), and *La Verbena de la Paloma* (1897) by Tomás Bretón (1850–1923).

ZASULICH, zä-sōō'lyich, **Vera Ivanovna**, Russian revolutionist: b. Mikhailovka, Smolensk Province, Russia, 1851; d. 1919. She belonged to a family of the lesser nobility, but began to take part in revolutionary activities in early youth and at 18 was sentenced to two years' imprisonment. After her release she was again indicted and placed under surveillance until 1876. In 1878 the military governor of St. Petersburg ordered a political prisoner flogged because of a slight infraction of discipline. This created a great stir in revolutionary circles, and on February 5 Vera Zasulich shot and seriously wounded the general in his office, making no attempt to escape. A trial jury acquitted her, and the populace hailed the verdict with enthusiasm; but the authorities were alarmed and had the verdict set aside. Vera Zasulich escaped abroad and did not return to Russia until the amnesty of 1905. In 1900 she joined Vladimir Ilich Lenin and others in founding the émigré Marxist newspaper *Iskra*. When the Russian Social Democratic Party split in 1903, she associated herself with the Menshevik wing and opposed the October Revolution in 1917.

ZAUBERFLÖTE, Dīe. See MAGIC FLUTE, THE.

ZAUDITU, zou-dē'tōō (Eng. JUDITH), empress of Ethiopia: b. 1876; d. Addis Ababa, Ethiopia,

April 3, 1930. The daughter of Menelik II, she ascended the throne as "queen of kings" in 1917 after Menelik's grandson, Lij Yasu, who had succeeded him, was deposed. At the same time Ras Tafari Makonnen (later Haile Selassie) was made regent. Conflict ensued between Zauditu and Ras Tafari over his efforts to liberalize and modernize the country and to bring about its admission to the League of Nations, which he finally did in 1923. In 1928 he forced Zauditu to name him king. Thereafter, in spite of an unsuccessful attempt by her former third husband, Ras Gagsu, to restore her authority, she exerted little political influence, but retained her title until her death. See also ETHIOPIA—History.

ZAWIERCIE, zä-vyēr'chē, city, Poland, in the Province of Katowice, on the Warta River, 25 miles southeast of Czeszochowa. It is situated adjacent to important coal- and iron-mining districts, and manufactures glass, textiles, chemicals, and metal products. Zawiercie was in Russian Poland from 1815 until the end of World War I, when it was incorporated in the newly reconstituted Polish state. During World War II it was occupied by the Germans, who gave it the name of Warthenau. It was returned to Poland after the war. Pop. (1981) 63,725.

ZEÄ, the name by which the Greek island of Kea in the Aegean Sea was sometimes known in the Middle Ages. See KEA.

ZEALAND, zē'länd (Dan. SJÆLLAND), island, Denmark, largest island of the kingdom, lying east-southeast of the Jutland Peninsula between the Kattegat and the Baltic Sea. It is separated from Sweden by the Øresund and from the island of Fyn by the Great Belt. Zealand is over 80 miles long and up to 72 miles wide, with a very irregular coastline and a total area of 2,709 square miles. It has no mountains, but the surface is variegated, with fertile fields and small hills intersected by canals. Large crops of grain are produced, and there are excellent pastures and rich fisheries. Copenhagen, the national capital, is on the east coast. The historic cities of Helsingør (Elsinore) and Roskilde are also on Zealand. Administratively the island is divided into five counties: Copenhagen (including Roskilde County District), Frederiksborg, Hållbæk, Sorø, and Præstø. Pop. (1976 est.) 1,987,549. See also DENMARK.

ZEALAND, a province in the Netherlands. See ZEELAND.

ZEALOTS, zē'l'ōts (Lat. *zelotes* from Gr. *zelotai*), in ancient Jewish history, champions of traditional ways of Jewish life and opponents of Roman rule in Judaea. As adversaries of the Graeco-Romanizing activities of King Herod the Great (r. 37–4 B.C.), the Zealots inaugurated a program to restore the purity of Judaism and then developed a political party to oppose Roman overlordship. In their fanatical zeal they attracted many outlawed assassins and bandits, who terrorized Jews that sympathized with the Roman occupation force. These corrupt elements converted the organization into a crusade against the Romans and were chiefly responsible for the Romano-Jewish War of 66–70 A.D. The war resulted both in Jerusalem's destruction and the Zealots' own extermination, for the Romans eventually extirpated such

resisters as remained after the capital's surrender.
P. R. COLEMAN-NORTON.

ZEBRA, zē'brā, a horselike animal, of the genus *Equus*, native to open grassy areas in Africa south of the Sahara. It is strikingly patterned with narrow alternate bands—black or blackish brown and white or yellowish—over much or all of the body. It is between the horse and the ass in size and form, and has a rather heavy head, short mane, stout body, and tufted tail. Grévy's zebra (*E. grevyi*) of the semidesert in northeastern Kenya, Ethiopia, and Somalia is the largest, nearly 80 inches high at the shoulder and banded almost completely down to the hoofs. The mountain zebra (*E. zebra*) of Cape Province and South West Africa is the smallest, about 48 inches tall; its numbers have been greatly reduced, in some areas to extinction. Most common and widely distributed over eastern Africa is Burchell's zebra (*E. burchelli*), of which many local races have been described.

Zebras live in herds, small or large, on open plains or hills, avoiding forests; the herds are often mixed with hartebeest, wildebeest, or other gregarious antelopes. They graze mostly in morning and evening, go to water at intervals, and rest usually by standing. When herds are excited, they gallop off speedily; near farms they may crash through fences and cause domestic horses or asses to stampede. Gestation lasts about 12 months, and the young run with the mother from birth. Zebras are prey for lions and leopards, yet may stand near the big cats when the latter are not hunting. African natives eat zebra flesh, but to other persons it has a strong flavor.

During the 19th century some zebras were caught in corrals and trained to harness; some were even used to draw stages in southern Africa; but they lacked the stamina of horses or mules. On the other hand, the zebra is sturdier, more compact, and speedier than either mule or ass, and is immune to blood diseases carried by flies and commonly fatal to imported horses or mules.

Burchell's zebra (*Equus burchelli*), photographed in Nairobi National Park, Kenya.

C. A. Spinage from Annan Photo Features

Hybrids of zebra-horse and zebra-ass have been produced in the hope of obtaining domestic draft animals combining the desirable features of both parents, but these efforts have been unsuccessful because the hybrids have been infertile.

The quagga (q.v., *E. Quagga*) of southern Africa, which is now extinct, was a relative of the zebras.

TRACY I. STORER,
Professor of Zoology, Emeritus, University of
California at Davis.

ZEBRA GRASS or **EULALIA**, a variety of perennial grass (*Miscanthus sinensis zebrinus*), from six to nine feet tall, native to eastern Asia and cultivated and found as an escape in the eastern United States. The leaf blades are banded or zoned with light-colored horizontal stripes. Two other varieties of this grass are cultivated as ornamentals: var. *variegatus*, with longitudinal stripes on the leaf blades, and var. *gracillimus*, with very narrow leaf blades. Discoloration (or variegation) in these grasses may occur as the result of a noninfectious disease, chlorosis, caused by a deficiency in certain chemical elements or other natural nonparasitic causes.

THEODOR JUST.

ZEBRA PLANT, a herb (*Calathea zebrina*), of the arrowroot family, Marantaceae. A native of Brazil, it is one of the commonest potted plants in warm greenhouses and is grown outdoors in Florida and other warm climates. The plants may be three feet high and produce as many as 20 leaves from a short base. The oblong-lanceolate unequal leaf blades may be two feet long and half as broad. They are a glistening deep green in color, with pale transverse bands on the upper side and purple bands on the lower. The violet and white flowers form a nearly globular spike. The plants are propagated by dividing their underground parts. Over 30 species of this tropical American and African genus are cultivated as ornamentals.

THEODOR JUST.

ZEBRAWOOD, zē'brā-wōōd, a name applied to several tropical trees of the pulse family, Leguminosae, but in the trade limited to *Brachystegia milbraedii* of central Africa. Wood of this species is pale brown and regularly or irregularly marked with dark brown stripes of varying widths, easily worked and lustrous when finished. The name is also applied to any of the five or six species of *Centrolobium* found from Panama to Ecuador and southern Brazil; wood of this genus is yellow or orange, usually variegated and sometimes marked by purplish streaks. *Marmaroxylon racemosum* of Dutch and French Guiana and Brazil is also called zebrawood; its wood is light yellow or orange brown and conspicuously marked by irregular purplish brown streaks. It is less easily worked and finished than the other woods.

ZEBULUN, zēb'yā-lən, or **ZABULON**, zāb'yā-lən, in the Old Testament, the tenth son of Jacob, the sixth by Leah (Genesis 30:19-20). He was the patronymic hero of one of the northern tribes

of Israel, mentioned for its heroism in the ancient Song of Deborah (Judges 5:18) and also in the Blessing of Jacob (Genesis 49:13): "Zebulun shall dwell at the shore of the sea; he shall become a haven for ships; and his border shall be at Sidon." The tribal territory lay in the fertile foothills north of the Plain of Jezreel and included the town of Nazareth (although Capernaum belonged to Naphtali; consult Matthew 4:12-16). The territory also lay along the prehistoric highway, the "Way of the Sea" (Isaiah 9:1), which doubtless yielded a certain prosperity, but also opened the land to the conqueror. Tiglath-pileser III carried away many captives to Assyria in 733 B.C. (II Kings 15:29), after which the tribe disappeared from history; but the name lingered on in the region, and after the exile was still remembered. Even in the New Testament it is used to identify the region.

FREDERICK C. GRANT.

ZECHARIAH, zĕk-ă-rî'ă (sometimes **ZACHARIAH**; in Douay Bible, **ZACHARIAS**), a common Old Testament name meaning "Jehovah has remembered." Of some 29 persons bearing this name mentioned in the Bible, the following 4 are most important:

(1) in II Chronicles 24:20-22 (but not in the parallel account in II Kings 11, 12) Jehoiada, the reforming priest of Judah who overthrew Queen Athaliah (c. 837 B.C.), is said to have had a son Zechariah who continued his father's reforming policies and was murdered in the Temple court at the instigation of King Joash. This is the Zechariah referred to in Matthew 23:35, where he is erroneously called "the son of Barachiah" (see nos. 3 and 4). The connection made in Matthew between the shedding of his blood and that of Abel arises from the fact that the story of Abel is told in Genesis, the first book of the Old Testament, whereas that of Zechariah is told in Chronicles, which, in the Hebrew canon, is the last book; these two murders, the first and the last in the Old Testament, are taken to illustrate the whole history of Israel's treatment of her prophets and righteous men.

(2) Zechariah, the son of Jeroboam II, was the last king in Israel of the dynasty of Jehu. His assassination by Shallum (II Kings 15:8-12) at the end of a six months' reign (747-746 B.C.) marked the end of a long era of national prosperity and the beginning of the period of near anarchy that preceded the extinction of the kingdom in 721 B.C.

(3) Zechariah, the son of Jeberechiah, is mentioned as a contemporary prophet by Isaiah (8:2) and seems to have been a person of some importance. Nothing more is known of him. He seems to have been confused at times with the greater prophet Zechariah who was active some two centuries later (see no. 4).

(4) Zechariah, the 11th of the minor prophets as the books are at present arranged, was an important religious leader of the Persian age who, with his contemporary Haggai, was chiefly instrumental in arousing Zerubbabel the governor to begin rebuilding the Temple of Jehovah. In Ezra 5:1 he is called "the son of Iddo" but in Zechariah 1:1, 7 "the son of Berechiah, the son of Iddo." The addition of the words "the son of Berechiah" is probably the result of his being later identified with the 8th century prophet Zechariah, the son of Jeberechiah (see no. 3). Nothing is known of his personality or career be-

yond the brief reference in Ezra and what may be inferred from the first eight chapters of the book which bears his name.

From Nehemiah 12:4 we learn that Zechariah's father Iddo had been among the priests who returned from exile in Babylon under the leadership of Zerubbabel and Joshua. For many years (538-520 B.C.) the people were so busy trying to reestablish their own national life under unfavorable circumstances that they could give no attention to rebuilding the Temple; but at last, in the sixth month of the second year of Darius' reign (520 B.C.), Haggai succeeded in stirring up enthusiasm for the project when he attributed the drought and famine that plagued the country to God's anger at the people's lack of zeal for His house (Haggai 1:9-11). Later in the same month Zerubbabel and Joshua began work on the Temple (Haggai 1:14-15), and two months later Zechariah joined his voice to that of Haggai (Zechariah 1:1).

All the prophecies of Haggai are dated within a brief three-month period, but Zechariah's prophetic ministry continued for at least two years (Zechariah 7:1), and the range of his interests was far wider than that of his principal contemporary. Haggai was almost entirely preoccupied with the rebuilding of the Temple, but Zechariah explicitly touches on this matter only incidentally (1:16; 6:13, 15; 8:9), at least in the oracles that have been preserved. He was far more deeply concerned with the spiritual and moral condition of the nation (7:9-10; 8:16-17). One feels in him much of the spirit of "the former prophets," of whom he speaks with evident admiration (1:4; 7:7, 12). Both he and Haggai were involved in an unsuccessful plan of the Jews to take advantage of disturbed conditions in the Persian Empire in order to declare their independence and to crown Zerubbabel as king-messiah. This is reflected in Haggai's last oracle (2:20-23) and in a mysterious oracle of Zechariah (6:9-15), which has come down to us in a deliberately mutilated form. The failure of this venture seems to have marked the end of Haggai's career, but Zechariah was led to turn his eyes toward the more distant future and to place his trust in what God, rather than men, would do (chap. 8). The colorful visions of Zechariah recorded in chapters 1-6 represent an important stage in the transformation of the older type of prophecy into the later apocalyptic type. In this respect he stands midway between Ezekiel and Daniel 7 to 12.

ROBERT C. DENTAN,
Professor of Old Testament Literature and Interpretation, The General Theological Seminary, New York City.

ZECHARIAH, Book of, in the Old Testament. Like the other larger prophetic books, it is not a unified work from a single hand, but a collection of partly heterogeneous materials from different authors and periods. It falls into two main divisions: chapters 1-8, which may with confidence be connected with the prophet Zechariah, son of Iddo, who was active in the last quarter of the 6th century B.C. during the Persian age; and chapters 9-14, which are of very different character and probably belong to the Greek period (that is, the end of the 4th century B.C. or later). This latter part is commonly called *Second Zechariah* or *Deutero-Zechariah*; since chapters 12-14 seem to be of different origin from 9-11, they are

sometimes distinguished further as Third Zechariah or Trito-Zechariah. The authentic oracles of Zechariah in chapters 1-8 have hardly any elements in common with these later chapters.

The 6th century Zechariah speaks in a series of elaborate visions and is much concerned with the Temple and the Temple ritual. The personalities mentioned and the circumstances reflected are those of the Persian age, and the world in which he lives is a world at peace; the problems discussed are chiefly those concerning the internal life of the people of God. In the second part of the book the picture is a very different one. There are no visions at all (in the sense of those in chapters 1-8); no historical personalities are mentioned by name, and some that are referred to cryptically have sometimes been identified with figures in the Greek period; several of the oracles reflect a time of war and are extremely militant, not to say ferocious, in tone; the problems reflected are chiefly those which arise from oppressive foreign rule and the effort to adjust to it. Besides these considerations of content it should be noted that chapters 9 and 12 each has the separate title "The burden [or oracle] of the word of the Lord," which sets them off from the chapters that precede and is found elsewhere in the Bible only in Malachi 1:1. There can be little doubt that chapters 9-14 contain a series of anonymous oracles that originally had no connection with the prophecies of Zechariah and should be treated separately from them.

The first part of the book also falls into two parts: chapters 1-6, which consist of a series of visions, and chapters 7-8, in which the words of the prophet appear in more conventional form. Some attempts have been made to attribute this distinction to a difference in authorship, but it appears more likely that it is due to the altered circumstances of writing. The greater sobriety of expression may well reflect the prophet's disappointment at the failure of the attempt to gain the throne for Zerubbabel.

Chapters 1 to 8.—The book opens (1:1-6) with a brief oracle of quite general character, urging repentance and expressly connecting the work of Zechariah with that of "the former prophets." In mood this oracle is more closely connected with chapters 7-8 than with the visions that follow. It is dated in the 8th month of the second year of Darius, two months later than the first pronouncement of Haggai (Haggai 1:1). The major portion of the book consists of a series of eight nocturnal visions (1:7 to 6:8), which are dated on the 24th day of the 11th month of the same year; there is also the coronation oracle (6:9-15). In each of the visions the prophet has an angelic interpreter who explains to him the meaning of the strange things he sees.

In the first vision (1:7-17) Zechariah sees a group of horsemen who have returned to Jehovah after passing over the earth and report that all is quiet. The angel assures the prophet that even though nothing seems to be stirring upon the plane of history, yet God is at work and will restore His Temple and bring prosperity to His people. The second vision (1:18-21) pictures four horns cut off by four smiths, obviously representing the destruction of Israel's oppressors by supernatural forces, as in the later apocalypses. In the third vision of the series (2:1-5) a surveyor is seen at work measuring the future city of Jerusalem, which is to spread abroad without limit and without walls and is to be glorified and

protected by the presence of God within it. These first three visions constitute a unit in themselves, all three being designed to reassure a discouraged people that God's purpose would yet be fulfilled. This section of the book is appropriately brought to a close (2:6-13) by an oracle of a different character, attributed by some commentators to another hand, which calls on the exiles still in Babylon to return in faith to Palestine.

The next two visions have to do with Joshua and Zerubbabel, the spiritual and political leaders of the Jerusalem community. In one (chap. 3) Joshua the high priest is shown dressed in filthy clothing, probably representing the nation and its accumulated sins. By God's favor the people's guilt is taken away, and Joshua is raised to honor and power; the figure of Satan appears in this story, not as God's enemy but as a prosecuting attorney. The fifth vision (chap. 4) is complex, and the text exhibits some confusion, but the main point is the dignity given to Joshua and Zerubbabel.

Visions six and seven describe the moral purification of the community, first under the image of a written flying curse that extirpates evil in the land (5:1-4), and then in the picture of a woman, personifying wickedness, who is placed in a basket and transported to Babylon (5:5-11). The whole series of visions comes to a close with the reappearance (6:1-8) of the horsemen of the first vision, who report the eventual accomplishment of God's purpose and the "quieting" of his "spirit." In an appendix to the visions (6:9-15) the prophet reports that he was commanded to provide a crown for the king-messiah who was to build the Temple. Originally this must have been Zerubbabel, but after the failure of the plan to make him king the oracle was changed into its present enigmatic and confusing form.

Nearly two years after the night visions, and while the Temple was well on its way to completion, visitors from Bethel came to Jerusalem to ask whether they should continue to fast in commemoration of the destruction of the old Temple. This visit stimulated Zechariah to produce a series of oracles in chapters 7 and 8. In 8:18-23 he answers their question by declaring that the fasts are to be transformed into feasts because of the favor that God is now beginning to show His people. In the past He had sent them into exile as a punishment for their failure to obey Him, especially because they had not regulated their corporate life by principles of brotherhood and justice (7:4-14), but now it was His will that Jerusalem should be restored to its former glory. The future was very bright before them if they had learned the lesson of ethical obedience (8:1-17).

The authentic prophecies of Zechariah offer ample evidence that the spirit of the pre-Exilic prophets had not been entirely crushed by the experiences of the Babylonian Exile and the rise of a more formal type of priestly religion. Zechariah himself was a priest, deeply concerned with the rebuilding of the Temple and the resumption of its worship, but his final admonition to the people as he looked into the future was in the authentic tradition of the great prophets of old: "Speak ye every man the truth to his neighbor; execute the judgment of truth and peace in your gates; And let none of you imagine evil in your hearts against his neighbor; and love no false oath: for all these are things that I hate, saith the Lord."

Second Zechariah (Deutero-Zechariah) and Third Zechariah (Trito-Zechariah).—This part of the book presents the reader with material of an entirely different type. Critical opinion is unanimous in separating these oracles from the rest of the book, although there is still some difference of opinion as to whether all of them come from the Greek period; a few scholars still maintain that the earlier chapters contain material which somehow survived from the pre-Exilic age. At one time there was a strong tendency to relate some of these enigmatic oracles to events in the age of the Maccabees (from 167 B.C.), but it seems increasingly doubtful that anything could have been added to the canon of the prophets at so late a date. Most probably they reflect the rise of Greece under Alexander the Great (c. 336–323 B.C.) and the obscure years of Ptolemaic rule in Palestine (c. 312–198 B.C.). The “Egypt” and “Assyria” referred to in 10:10–11 would then be Ptolemaic Egypt and Seleucid Syria. Even apart from the question of date, no part of the Old Testament presents so many problems to the interpreter as these mysterious chapters. Strangely enough, no less than four verses in this brief section are connected by the New Testament with the last days of Jesus (9:9; 11:12; 12:10; 13:7). In view of the great diversity of content and style within the chapters, it is better to think of them as a collection of miscellaneous oracles from several sources than as the product of a single mind.

The first oracle (9:1–8) was probably inspired by the triumphant southward march of Alexander the Great after the Battle of Issus (333 B.C.). This was taken by the author of 9:9–12 as preliminary to the coming of the Messiah and the return of the exiles to the Promised Land. In 9:13–17, where the Greeks are explicitly mentioned (although some scholars think these words are a later addition), they appear as enemies, and the sons of Israel are promised victory over them. This hostile attitude toward Greek rule seems to point to a later period (probably that of the Ptolemies), and the two following chapters (10 and 11), with their picture of a nation exploited by its “shepherds” (foreign rulers), help to explain the change of feeling. Two brief separate oracles (10:1–2; 11:1–3), which originally had nothing to do with this general context, have been artificially inserted here simply because the word “shepherd” occurs in each of them. The identity of the good shepherd of 11:4–14, who is repudiated by his flock and in turn repudiates them, is utterly mysterious, and the whole action described there is perhaps better understood as a prophetic parable than as an account of historical events.

A new title separates chapters 12–14 from the preceding section, and this fact, together with the new style and subject matter, has led to their being treated as a unit under the title Trito-Zechariah, a usage which may be retained for convenience although even these three chapters do not seem to come from a single hand. Their most notable characteristic is a strong tendency toward the apocalyptic. In 12:1 to 13:6 and chapter 14 there are parallel accounts of the last great battle of world history, in which the nations of the earth, representing the united forces of evil, are to be destroyed by the supernatural action of God; this is one of the stock features of the usual apocalyptic scheme. Especially interesting is the prediction that the institution of prophecy, which had evidently fallen into disgrace by the

writer's time, is to be abolished (13:2–6). A brief section at the end of the chapter (13:7–9) is out of place and belongs with the shepherd oracles of chapter 11.

Deutero-Zechariah and Trito-Zechariah, difficult as they are to interpret, are exceedingly valuable as giving us at least brief, if enigmatic, glimpses into the mind of the Jews in a period that is otherwise almost completely unknown. Their ethical tone is not very high, and there is a savage antipathy to foreign peoples (9:15; 14:12) that is rarely equaled in the rest of the Old Testament. Nevertheless one notes, on the credit side, that in the future kingdom of God the Philistines are to be welcomed as proselytes (9:7), the messianic ruler is to be a king of peace (9:9–10), and the whole section breathes a firm confidence that God rules over history and His good purposes cannot be defeated.

ZEDEKIAH, zēd-ə-kī'ə, the last king of Judah of the house of David: c. about 598–587 B.C. A younger son of Josiah, he was originally named Mattaniah. When Nebuchadnezzar (Nebuchadrezzar) captured Jerusalem in 598 B.C., the 18-year-old king Jehoiachin surrendered and was carried away to captivity in Babylon along with “all the princes, and all the mighty men of valor, ten thousand captives, and all the craftsmen and the smiths; none remained, except the poorest people of the land” (II Kings 24:14, Revised Standard Version). Mattaniah, Jehoiachin's uncle, was left in Jerusalem as regent and was given the name Zedekiah (righteousness of Jehovah) by the conqueror. Although Zedekiah took an oath of allegiance to Nebuchadnezzar, he was unable, in spite of the warnings of Jeremiah, to resist the dissatisfaction of his subjects and their growing desire for independence. He entered into negotiations with neighboring states, and when Egypt organized an expedition into Asia in the 9th year of his reign, he revolted along with some of the other cities. Nebuchadnezzar sent troops against Jerusalem; an attempt by Egyptian forces to relieve the city failed; and it fell after undergoing famine and other terrible hardships for a year and a half. Zedekiah escaped but was captured and taken to Nebuchadnezzar at Riblah. His sons were slain, and he was blinded and sent to Babylon to spend the rest of his days in prison. Nebuchadnezzar's captain of the guard was sent into Jerusalem to plunder and destroy the city, leaving only “some of the poorest of the land to be vinedressers and plowmen” (II Kings 25:7).

Besides II Kings 24, 25, Zedekiah's story is told in II Chronicles 36 and in scattered chapters of the Book of Jeremiah. Various passages in Ezekiel (notably chaps. 12, 17) also refer to him.

ZEEBRUGGE, zā'brüg-ə (Fr. ZEEBRUGES), town, Belgium, in West Flanders Province, on the North Sea, about 10 miles north of Bruges. It was artificially created in the early 19th century to give Bruges an outlet to the sea, and is linked to Bruges by a canal 230 feet wide and 7 miles long. A mole, 9,843 feet long, protects the harbor. During World War I the town became famous through the daring raid undertaken on April 23, 1918, by the British admiral Sir Roger John Brownlow Keyes, which succeeded in making the port unusable for the German submarine flotilla which had been stationed there. A museum commemorates this feat. The town has a population of less than 5,000.

JAN-ALBERT GORIS.

ZEELAND, zē'lənd, Du. zā'lānt (formerly known also as ZEALAND), province, the Netherlands, in the extreme southwest, on the North Sea, bordering Belgium. Its area of 651 square miles comprises the land about the estuary of the Scheldt (Schelde) River and the offshore islands of Walcheren, North Beveland, South Beveland, Schouwen-Duiveland, Tholen, and Sint Philipsland. Some of these are now peninsulas rather than islands, having been connected with the mainland by dikes, roadways, and railway—South Beveland, Tholen, and Sint Philipsland with the mainland, and Walcheren with South Beveland. The capital of the province is Middelburg, on Walcheren. A substantial part of Zeeland, formerly unproductive salt marshes and largely submerged land, has been reclaimed by an elaborate system of dikes, dams, and draining systems, which have made agriculture possible on a large scale. These great engineering projects suffered greatly during World War II, when the dikes were bombed by the Allies to wash out the Germans and prepare the way for commando landings. There were also severe floods in the 1950's. After the war and the floods, however, work was resumed with new vigor; the Delta Plan, initiated in 1958, provided for further closure of the estuary by a system of gigantic dams to protect the region from future floods and to provide still more land for agriculture.

Zeeland is predominantly agricultural, producing cereals, flax, vegetables, and fruits. Dairying and horse raising are important, as are fishing and oyster and mussel culture. Besides maintenance of the system of dams and dikes, industries include the production of coke and coal-tar chem-

icals, flax spinning, knitting, and shipbuilding. Although most of the population is scattered in small villages and isolated homesteads, there are two cities of considerable importance: Middelburg, and Vlissingen (Flushing), the chief port. Other towns include Terneuzen, Goes, Sluiskil, Sas van Gent, Veere, and Zierikzee. Picturesque villages with colorful costumes and old customs persist in many regions, attracting many tourists.

Zeeland, with other parts of the Netherlands, passed to the dukes of Burgundy in 1432, and when Mary of Burgundy married (1477) Maximilian of Austria (later emperor), it came under the rule of the Habsburgs and hence (1555) of Spain. In 1579 it participated in the Union of Utrecht (see UTRECHT, UNION OF), and during the Eighty Years' War which the Netherlands waged for independence from Spain, it performed great deeds of heroism. Pop. (1960) 283,914.

ZEEMAN, zā'mān, Pieter, Dutch physicist: b. Zonnemaire, Zeeland, the Netherlands, May 25, 1865; d. Amsterdam, Oct. 9, 1943. After studying at the University of Leiden, he became lecturer in physics there (1897–1900). His discovery of the spectroscopic phenomenon known as the Zeeman effect in 1896 brought him many international honors, including the 1902 Nobel Prize in physics, which he shared with Hendrik Antoon Lorentz. In 1900 he became professor of physics at the University of Amsterdam and in 1908 was also made director of the Physical Institute which was founded there. He experimented extensively with the propagation of light in vibrating media and published works in the field of magneto-optics, including *Messungen über das kerrsche magneto-optische Phänomen* (1893); *Experimentaluntersuchungen über Teile, die kleiner als Atome sind* (1900); *Magneto-optische Untersuchungen* (1914); and *Verhandelingen . . . over magneto-optische versuchinselen* (1921). See also ZEE-MAN EFFECT.

ZEEMAN EFFECT. When a source of light radiation is placed in a homogeneous magnetic field, a spectrum line from the source is usually split into a number of separate components. In special cases the lines are shifted but not split. This influence of a magnetic field on the behavior of spectrum lines is called the Zeeman effect after the Dutch physicist Pieter Zeeman (q.v.), who discovered the effect in 1896. The electron theory

Netherlands Information Service

of Hendrik Antoon Lorentz predicted and explained completely the so-called normal Zeeman effect (see *ELECTRON THEORY—The Zeeman Effect*). In 1902 Zeeman and Lorentz jointly received the Nobel Prize in physics for their work on this phenomenon.

The Zeeman components are polarized parallel or perpendicularly to the magnetic lines of force (π or σ components, respectively) if the light is observed at right angles to the magnetic field (transverse Zeeman effect). If the observations are made parallel to the lines of force (usually through a hole in the magnet pole pieces), the π components are absent, and the σ components show left- or right-circular polarization (Fig. 1). See also POLARIZED LIGHT.

Fig. 1. The normal Zeeman effect. A, line without magnetic field; B, Zeeman pattern when viewed at right angles to direction of magnetic field; C, same when viewed parallel to field.

Absorption lines show the same type of Zeeman effect as do emission lines (inverse Zeeman effect) when the absorbing substance is placed in a magnetic field.

Clear Zeeman effects are seen most easily in atomic spectra, and less commonly in molecular spectra. Pronounced Zeeman effects are found in the absorption and fluorescence spectra of paramagnetic ions in crystals.

The simplest case, and the only one that could be explained by the prequantum classical theory, is the normal Zeeman effect. It shows three components—the middle one at the place of the original line π -polarized, and the outer two σ -polarized. Their separation from the central component of frequency ν_0 (see Fig. 1) is proportional to the magnetic field strength H (in gauss) and is in wave-number units (cm^{-1}) $eH/4\pi mc^2$, where e is the charge of the electron, m its mass, and c the velocity of light. This quantity $\alpha = eH/4\pi mc^2 = 4.6687 \cdot 10^{-5} H \text{ cm}^{-1}$ is often called the Lorentz unit, and line separations observed in the Zeeman effect are usually expressed in these units.

The anomalous Zeeman effect, which is actually the most prevalent one, shows a more complicated pattern. There may be any number of components. In most cases the separations are rational fractions of the Lorentz unit. The distances between the components are proportional to H for isolated lines (linear Zeeman effect). Photographs showing the anomalous Zeeman effect of the yellow sodium doublet are given in Fig. 2.

low sodium doublet are given in Fig. 2.

When the field-free distance between two or more lines is not large compared with the Zeeman separation observed in the magnetic field, the Zeeman separations are no longer proportional to

E. Ritter and E. Loh, Johns Hopkins University

Middle: Perpendicular (σ) components of emission lines. Top: The unpolarized effect in absorption (inverse effect). Magnetic field was slightly lower for top photograph.

H. For small deviations from linearity there is a part proportional to the square of H (quadratic Zeeman effect), but in general the law determining the separation of the components is of a more complicated nature, in which case the Paschen-Back effect, or a related effect, occurs. The pattern is no longer symmetric about the field-free line, and strong intensity anomalies occur. A typical Paschen-Back effect occurs in a spectral multiplet when the Zeeman components of neighboring multiplet components approach each other. It would occur in the example of Fig. 2 if the field were so greatly increased that the right component of the left line came close to the left component of the right line. The mechanism of the typical Paschen-Back effect is that the applied magnetic field breaks the magnetic coupling of the electron spin with the magnetic moment of the electron orbit.

Interpretation.—Lorentz in 1896 gave a complete theory of the normal Zeeman effect based on the then prevalent classical electron theory. This theory recognizes moving electrons in the atom, the frequencies of their motion corresponding to the observed frequencies of the spectrum lines. In a magnetic field, onto the motion of the electrons there is superimposed the so-called Larmor precession about the axis of the field. This pre-

cession has a frequency $\omega_L = eH/4\pi mc$, the so-called Larmor frequency. The original frequency ω_0 is modulated by the Larmor frequency so that the three frequencies ω_0 , $\omega_0 + \omega_L$, $\omega_0 - \omega_L$ are observed.

The theory of Lorentz could give no account of the anomalous Zeeman effect. However, the subsequent introduction of electron spin together with the quantum theory of the atom led to a complete account of all details of any observed Zeeman effects. According to the quantum theory, any spectrum line of frequency ν is due to a transition between two states of energies E' and E'' respectively according to the fundamental relation $h\nu = E' - E''$, where h is Planck's constant. Both the upper and lower states are modified in the magnetic field, but, because of electron spin, in different ways.

Nuclear Magnetic Resonance.—The atomic nucleus usually has a small magnetic moment that causes a spectrum line to be broken up into several narrowly spaced hyperfine-structure components. These components show a very characteristic Zeeman effect. When the transitions are those between the hyperfine-structure components, the effect is called nuclear magnetic resonance (NMR). NMR is now used extensively for the analysis of materials.

Paramagnetic Resonance.—The transitions between the adjacent Zeeman components of one electronic state have the frequency $\nu = ag$, where g is a factor that expresses the influence of the electron spin. For reasonable field strengths (several thousand gauss) these transitions are in the microwave region, where the experimental techniques are quite different from those used in optical spectroscopy. The transition frequencies (resonance frequencies) can be measured directly with high accuracy, so that extremely accurate values of g can be obtained. These have led to refinements in the theory of magnetic moments. A Zeeman splitting occurs only if the state has a magnetic moment, which is synonymous with saying that the state is paramagnetic. A substance is customarily but not exclusively called paramagnetic if its ground state is paramagnetic, and the paramagnetic-resonance experiments are usually carried out with such substances.

Zeeman Effect in Molecular Spectra.—The Zeeman effect in atoms results from the fact that the magnetic moment is oriented by the magnetic field and precesses about it. If a molecule has a magnetic moment, the latter is moved around by the rotation of the molecule, and this movement interferes with the orientation in the magnetic field. For this reason substantial Zeeman effects are the exception in molecular spectra. They occur when the molecule rotates not at all or very little, or when the electronic shell is so loosely attached to the nuclear frame that the shell can move independently under the influence of the magnetic field.

Zeeman Effect in Crystals.—There are crystalline solids that have sharp absorption or emission lines, especially at low temperatures. (The emission spectrum of a solid is usually a fluorescence spectrum, although other types of luminescence spectra can occur.) These are primarily salts of rare earths and to a lesser extent salts of the iron group and other transition elements. These crystal lines usually exhibit interesting Zeeman effects that depend on the orientation of the crystals. Fig. 3 shows a fairly complicated example of a crystal Zeeman effect.

H. M. Crosswhite, Johns Hopkins University

Zeeman effect in absorption spectrum of crystalline dysprosium chloride. Numbers on left indicate strength of magnetic field in kilogauss. In upper part magnetic field is parallel to crystal axis; in lower part, perpendicular.

Applications.—Some of the more direct applications of the Zeeman effect are given in the following paragraphs. There are numerous others.

Analysis of Spectra.—For the analysis of complicated spectra, the knowledge of the quantum numbers associated with each spectrum line is very important. The Zeeman splittings depend on these numbers in a very pronounced way, so that the analysis of an observed Zeeman pattern will give the desired quantum numbers. The Zeeman effect, therefore, has always been an important tool for the analysis of complex spectra.

Measurement of Magnetic Fields.—For a known spectrum line the splittings can be used to obtain the strength H of the magnetic field. This is of no great importance if there are independent methods for measuring the field. However, for very hot or electrically disturbed substances (plasmas) and for inaccessible bodies (the sun and stars), the Zeeman effect offers the only method for magnetic field strength measurements. In this way it was found that sunspots have a considerable magnetic field but that there is a smaller but noticeable field on other parts of the surface of the sun and other stars. Ingenious modifications of the Zeeman effect have been used by astrophysicists to demonstrate the small magnetic fields of stars.

Relation of Zeeman Effect to Paramagnetic Properties.—Paramagnetism of a substance is caused by the fact that the constituent atoms, molecules, or ions have a net magnetic moment (see MAGNETISM—*Diamagnetism and Paramagnetism*). This same property is also responsible for the Zeeman effect. There is thus a close relationship between the Zeeman effect and the paramagnetic susceptibility. In fact, when the former is known, the susceptibility can be completely calculated. The inverse is much more difficult. The simplest case is when there is only one state that, in a magnetic field, is split into two com-

ponents with separation sa . In this case the magnetic susceptibility at the absolute temperature T is $3Ns^2\beta^2/4kT$ (Curie's law), where N is the number of paramagnetic ions per unit volume, k is Boltzmann's constant, and $\beta = eh/4\pi mc$ is the so-called Bohr magneton. This case is realized in many crystals when the magnetism is due to the electron spin only. When there are more than two Zeeman components or several levels occupied, or when the substance is anisotropic, the formulas are somewhat more complex; however, in this case also the susceptibility can be obtained from the Zeeman splittings by a relatively easy calculation.

When neighboring paramagnetic ions influence one another, the situation becomes more complicated, and this is reflected in the Zeeman effects. If the mutual interaction is large, the substance is ferromagnetic. Thus far the Zeeman effect of ferromagnetic substances has been studied only in a few exceptional cases.

ZEILA, za'lä (formerly ZEYLA), town, Somalia, on the Gulf of Aden, 25 miles southeast of Djibouti, French Somaliland. Formerly one of the largest centers of the slave trade on the East African coast, it now concentrates on cattle and sheep raising, pearl fishing, and exportation of hides, skins, gums, and coffee; imports include dates, silks, cotton, and rice. After the decline of Aksum (Axum) in the 6th century A.D., Zeila became the most important port for the trade of the Abyssinian highlands. In the 15th century it was occupied by the Turks, but in 1516 they were displaced by the Portuguese, who burned the town. For the next three centuries the Arab sherifs of Mocha (Mukha) were in control, succeeded by the Egyptians in 1870 and the British in 1884. The British protectorate ended with the creation of the independent Republic of Somalia in 1960. Most of the inhabitants are of mixed Hamitic and Semitic blood. The population varies, according to the seasons, between 3,000 and 7,000.

JOHN RALPH WILLIS, JR.

ZEISBERGER, zis'bür-gär, Ger. tsis'bër-gär, David, American-Moravian missionary among the Indians: b. Zauchtenthal, Moravia (now in Czechoslovakia), April 11, 1721; d. Goshen, Ohio, Nov. 17, 1808. Educated at Herrnhut, Saxony, the headquarters of the reorganized Moravian Church, he emigrated to Savannah, Ga., in 1738 with the aid of Count Nikolaus Ludwig von Zinzendorf to join the Moravian colony there. He soon proceeded to Pennsylvania, where he helped to found the towns of Bethlehem and Nazareth in 1740-1741. Zeisberger learned the Indian language, lived among the people, made many converts to the Moravian faith, and played an important role in keeping peace between the Indians and white settlers on the Pennsylvania frontier. Moving westward, in 1772 he founded the Christian Indian village of Schoenbrunn in the Tuscarawas Valley, the first town established in

Ohio, which has been reconstructed in Schoenbrunn Memorial State Park. This was soon followed by the nearby settlement of Gnadenhütten and others. During the American Revolution, however, the Indians were regarded with suspicion by both Americans and British, and the settlements were broken up. Zeisberger was made prisoner in 1781 by the British, and his Gnadenhütten converts were massacred the next year. After his release in 1782, he set up missions in Michigan, Canada, and Ohio. In 1798 he settled in Goshen with some of his Indian followers and spent the rest of his life there.

Zeisberger published *A Delaware-Indian and English Spelling-Book* (1776); *A Collection of Hymns for the Use of the Christian Indians* (1803); and *Sermons to Children* (1803), in the Delaware language. Long after his death his *Diary* (1885) was brought out, and *Zeisberger's Indian Dictionary, English, German, Iroquois—the Onondaga and Algonquin—the Delaware* (1887).

ZEISS, tsis, Carl, German optician and manufacturer of precision optical instruments: b. Weimar, Germany, Sept. 11, 1816; d. Jena, Dec. 3, 1888. Educated for the medical profession, he founded the Carl Zeiss factory at Jena in 1846, at first specializing in microscopes. In 1866 he appointed Ernst Abbe (q.v.), the physicist, then an instructor at the University of Jena, as director of research, taking him into partnership in 1875. With Abbe's assistance in improving Zeiss' earlier instruments, the firm became world famous for the optical instruments it produced. After Zeiss' death, Abbe succeeded him as sole owner, reorganizing the business on a cooperative basis as Carl-Zeiss-Stiftung with branches throughout both hemispheres. It broadened its activities to include cameras, telescopes, and, just before and after World War I, planetariums (see also PLANETARIUM). Some of its other early contributions were Abbe's condenser for the compound microscope (1870), his refractometer for measuring the refractive index of substances (1874), the anastigmatic camera lens (1889), and the stereoscopic range finder (1893).

ZEIST, zist, town, the Netherlands, in Utrecht Province, five miles east of Utrecht. The attractive countryside, where rolling wooded land meets the flat polders, has made it a residential center and a popular summer resort, and there are many villas in the neighborhood, most of them modern. There is some manufacturing. A historic castle has been converted into a Moravian monastery. The Moravian settlement dates from 1746. Pop. (1961) 52,353.

ZEITZ, tsits, city, Germany, on the Weisse Elster River, 25 miles southwest of Leipzig. Its industries include brewing and the manufacture of pharmaceuticals, machinery, and pianos. A 10th century church, the 16th century city hall, and the 17th century Moritzburg castle (replacing one originally built in the 10th century) are points of interest. Zeitz was the seat of a bishopric, established by Emperor Otto I, from 968 to 1028, and was the capital of the duchy of Saxe-Zeitz from 1563 to 1718. It passed under the control of Prussia in 1815. After World War II it was included in the German Democratic Republic (East Germany); from 1952 in Halle District. Pop. (1960) 45,200.

ZELAYA, sā-lā'yā, José Santos, Nicaraguan statesman: b. Managua, Nicaragua, 1853; d. New York, N.Y., May 17, 1919. A leader of the Liberal Party, he came to power as president in 1893 after a successful revolution against the Conservative incumbent, Roberto Sacasa. One of his first acts was to annex (1894) the previously autonomous Mosquito Indian reserve, forming the department that now bears his name. Zelaya did much to modernize the economy of Nicaragua, but his program aroused violent Conservative opposition, and he resorted more and more to dictatorial rule. It was also his ambition to unify the countries of the area, and in 1895 he succeeded in forming the Greater Republic of Central America, with Honduras and El Salvador; but this soon fell apart. Zelaya's regime became increasingly embroiled with its neighbors and resented United States efforts to intervene, although a conference in Washington in 1907 brought a measure of peace with the formation of the Central American Court of Justice. In 1909 a Conservative revolution against him received support from the United States after two American citizens fighting with the Conservatives were executed. Zelaya was compelled to resign and went into exile. See also CENTRAL AMERICA, DIPLOMATIC RELATIONS WITH; NICARAGUA—10. *History*.

ZELAYA, department, Nicaragua, in the eastern part of the country, on the Caribbean Sea, between Cabo Gracias a Dios Territory on the north and Rio San Juan Department on the south. Its area of 21,616 square miles constitutes about 40 percent of the total land area of the country. The capital is Bluefields, a Caribbean port at the mouth of the Escondido River. Other rivers draining into the Caribbean are the Huahua, Prinzapolca, the Rio Grande, and Punta Gorda. The Corn Islands (q.v.), off the coast, are leased to the United States.

The inhabitants of the department are mainly Mosquito (Miskito) Indians. The terrain is thickly forested, except along the coast, which is swampy. Mahogany, pine, and balsam woods are cut for export, and significant quantities of gold and copper are mined. Sugarcane and other agricultural products are grown.

The area was a British protectorate until 1860, when it was made an autonomous Indian reserve under Nicaraguan administration. It was annexed by Nicaragua in 1894, during the presidency of José Santos Zelaya (q.v.), for whom it is named. Pop. (1960) 72,214.

See also MOSQUITO COAST; NICARAGUA.

ZELLA, dzēl'lä, oasis, Libya, in Fezzan Province, in the Sahara, in the central part of the country, 105 miles southeast of Hun (Hon) and about 170 miles south of the Mediterranean coast. It is a caravan center and road terminus. The population raises figs, dates, barley, and cattle. During the time of El Magrizi (1365-1442), the Islamic empire of Kanem extended from Zella southwestward to Gao on the Niger River. Pop. (1954) 2,047.

JOHN RALPH WILLIS, JR.

ZEMSTVO, zēmst'vō; Russ. zyēm'stfo, the name for any of the provincial and county legislatures established in most of European Russia by Czar Alexander II in an edict of Jan. 13, 1864.¹ Estate owners, peasant villages, and town burghers were

¹ All dates are New Style.

each authorized to elect a fixed number of representatives to a three-year county zemstvo. The county zemstva (zemstvos) within a province then elected a provincial zemstvo. Executive boards were chosen by both county and provincial zemstva to provide legislative leadership. The zemstva had the power to levy minor taxes, fostered agricultural development, and took charge of roadbuilding, welfare work, local schools, and public health. Similar legislatures called city dumas were established by Alexander II in urban areas by an edict of 1870.

Zemstvo power, never strong, was greatly weakened by Czar Alexander III in an edict of June 24, 1890, which authorized provincial governors to choose the peasant delegates to county zemstva. By the same edict the provincial governors, who were appointees of the czar, were empowered to veto decrees of both county and provincial zemstva. In 1894 zemstvo leaders met in the first all-Russian zemstvo congress, but Czar Nicholas II forbade such congresses in the future. Beginning in 1901, however, zemstvo leaders held regular national meetings in secret. During 1904 this secrecy was discarded, and a zemstvo congress openly demanded that the czar authorize a national legislature and grant civil rights to the Russian people. The Union of Unions, formed in 1905 by zemstvo employees, played an important role in the revolution of that year. When Nicholas stopped this revolution by permitting the election of a national legislature (Duma) with limited power, zemstvo leaders formed the Constitutional Democratic (Kadet) Party, which wielded great influence within the Duma.

When World War I began in 1914, an all-Russian Union of Zemstva was formed, which contributed much to the war effort. The provisional government, which ruled Russia from March to November 1917 after the abdication of the czar, created new zemstva in Siberia and Central Asia. The Bolshevik Revolution of Nov. 6-7, 1917, however, gave power to dictator Vladimir I. Lenin, who on Jan. 6, 1918, destroyed the zemstvo system.

The zemstva were the first attempt in modern Russian history to achieve local democracy. They were capable and conducted much local improvement. Undemocratic czars restricted this democracy, however, and it was ended by communism.

ELLSWORTH RAYMOND.

ZEN BUDDHISM, zēn bōō'diz-am, a Buddhist sect that probably originated in India but is usually associated with the religious history of China and Japan. The term Zen is Japanese for "meditation"; the Chinese equivalent is Chan. A tradition, sometimes contested, ascribes its introduction in China to the Indian monk, Bodhidharma, in 520 A.D. Strongly influenced by Taoist mysticism, Zen flourished in China during the late T'ang dynasty (618-906) and for about 500 years thereafter, and made its way into Japan. With the decline of the old Japanese aristocracy, patrons of earlier esoteric Buddhist sects, and the rise of the warrior class in the 12th and 13th centuries, a sense of insecurity prevailed. Under these conditions, Zen struck permanent roots, as did the popular Amida Buddhism and the nativistic sect of Nichiren. See JAPAN—13. *Religion* (Indigenous Buddhism: 1200-1600).

In both its Chinese and Japanese practice, Zen represented a reaction against the histori-

Bodhidharma, a monk who is said to have brought Zen Buddhism to China from India about 520 A.D.

cally developed Buddhist sects and a reversion to the pristine teachings of the Buddha himself. (See **BUDDHA AND BUDDHISM**). Disdaining the worship of deities, rejecting scriptures, and scorning rituals, it placed the responsibility of achieving enlightenment (*satori*) upon the individual. Through meditation, it was believed, man might secure insight into the nature of reality by intuitive flashes; methods of attaining enlightenment differed, however, in Rinzai and Sōtō Zen, the two principal schools. The simplicity of technique and spirit of self-reliance of Zen strongly appealed to Spartan warriors in Japan, while its capacity to sharpen perceptive powers attracted intellectuals and artists. But its apparent heterodoxy also evoked the suspicion and even opposition of the more popular Buddhist sects.

With the ascendancy of Neo-Confucianism, officially sponsored from Sung (960–1279) and especially Ming (1368–1644) times on, Chan and Buddhism in general gradually declined in China. In Japan, however, Zen rose to new peaks of influence during the turbulent age of the Ashikaga shogunate (1338–1573), pervading art, literature, and drama. (See **JAPAN—16. The Fine Arts: Ashikaga; PAINTING—Eastern Art: Japanese Painting.**) During the later Tokugawa shogunate (1603–1867), an era of tranquillity, the appeal of Zen slackened. In the philosophical and psychological upheaval following World War II, however, Zen has enjoyed a domestic revival in Japan as well as a newborn popularity in the West. The Zen of the “beatnik,” esteeming nonconformity and self-indulgence, is, however, a blatant perversion of the philosophy.

HYMAN KUBLIN,

Professor of History, Brooklyn College of the City University of New York.

ZEND-AVESTA, zēnd ə-vest’ə, or **AVESTA**, the sacred book of Zoroastrianism, the ancient Persian religion that is still practiced by the Parsis of India and the Zardoshtis of Iran. The book contains the teachings of Zoroaster, hymns, prayers,

invocations, and liturgical, legal, and mythical materials. The Avesta is written in the Avestan language, an old Iranian language of the Indo-European family, closely akin to Sanskrit. The Avestan script was designed for this purpose about the 6th century A.D., based on the Middle Persian script, which in turn was derived from the Aramaic alphabet.

Components.—The extant Avesta is but a fragmentary remnant of what had been a much larger collection of religious writings. In its present form it is used chiefly for liturgical purposes, and contains the following parts:

(1) *Yasna* (sacrifice, worship), the main liturgical portion of the Avesta, including also the *Gathas* (songs), a collection of 17 metrical hymns, which are the oldest and the most important part of the Avesta. These poems are written in a more archaic form of Avestan and are believed to be the work of Zoroaster himself. They contain the fundamental teachings of the prophet as revealed to him by Ahura Mazda (Ormazd, Ormuzd), the supreme deity. The *Gathas* are mainly concerned with the dualism of good and evil, the duty of man in the face of this conflict, its ultimate outcome, and the final victory of Ahura Mazda and the forces of good, leading to the realization of a kingdom of heaven. They are remarkably free from references to liturgical and ceremonial observances, as well as to the Iranian deities and their cults, which appear in some of the later portions of the Avesta.

(2) *Visparad* (Vispered, all the lords), a minor liturgical text resembling *Yasna* in form and content. It consists mainly of invocations and praises of Zoroastrian deities and saints.

(3) *Yashts* (worship, hymn of worship), a collection of poetical hymns, mainly in verse, extolling Zoroastrian deities or angels. In composition the *Yashts* are later than *Yasna*, but in content they are older, revealing the polytheistic background of the Aryan religion and its naturalistic pantheon, appearing here in a Zoroastrian guise. Among the main *Yashts*, 21 in all, are those concerning the goddess of the waters; *Mithra* (*Mithras*), the old Indo-Iranian deity, representing in the Avesta the god of contract, truth, and light; and the departed souls of the righteous. The *Yashts* are of considerable poetic merit and particularly important from a mythological point of view.

(4) *Vendidad* (originally *Videv-dat*, law against false deities or demons), mainly a detailed priestly code, particularly concerned with the rituals, regulations, penalties, and expiations involved in purification. The first two chapters, however, are divorced both in content and style from the rest. The first chapter deals with a dualistic account of the creation of the regions of the earth. The second chapter tells the story of Yima, the first ruler of the world (in Vedic tradition, the first man), who is instructed by Ahura Mazda to save mankind, plants, animals, and fire from the approaching disastrous winter and destructive flood.

(5) *Minor Texts*. These are shorter, fragmentary pieces including prayers, litanies, invocations, denunciations, and supplications, often drawn from the other parts of the Avesta, for use both by the laity and the clergy.

(6) *Fragments*. These are disconnected pieces containing prayers, invocations, blessings, praises, and eschatological pieces surviving from the lost parts of the Avesta.

History.—The Avesta was written over a long period of time. The date of its oldest part, the Gathas, is connected with the date of Zoroaster, which has been the subject of conflicting conjectures. The date of the Gathas, however, is definitely not later than the first half of the 6th century B.C., a date supported by both the Zoroastrian tradition and the more competent scholars. The most recent parts of the Avesta may have been written as late as the 4th century A.D. under the Sassanid monarch, Shapur II. The Avesta varies considerably, therefore, in content and style, reflecting several phases of development in the Zoroastrian religion.

The fact that the greater part of the Avesta has been lost is deduced not only from Persian, Greek, and Syriac sources, but also from the fragmentary nature of the extant Avesta. *Dinkart*, a compendium of the Zoroastrian religion written in the 9th century A.D., gives a summary of the content of the 21 books of the Avesta that were extant in Sassanid times (c. 226–641 A.D.), although they were not all preserved at the time *Dinkart* was compiled. It is clear that the Avesta was of an encyclopedic nature, embodying both purely religious writings and the lore and science incorporated in the Zoroastrian religion. It suffered the loss of some of its parts in Alexander the Great's invasion of Persia (late 4th century B.C.) and the following period. Attempts were made later to restore, reconstruct, or enlarge the Avesta, notably under the Arsacid Vologesus I (r. 51?–277 A.D.), and the Sassanids Ardashir I (d. 241 A.D.) and Shapur II (r. 309–379 A.D.). The greater part of the Avesta was lost after the Arab invasion of Persia (7th century) and the advent of Islam, when the religion as well as the script of the country was changed and the language modified.

The Avesta was first brought seriously to the attention of the Western World through the efforts of a Frenchman, Abraham Hyacinthe Anquetil-Duperron (q.v.), who arrived in India in 1755 and returned to France seven years later, after surmounting innumerable obstacles, with manuscripts of the Avesta. His translation appeared in Paris in 1771 under the title, *Zend-Avesta, Ouvrage de Zoroastre*. Since then, Western scholarship has done much to provide a clearer understanding of the Avesta, which presents many difficulties.

ZENGER, zěng'ər, John Peter, American printer: b. Rhenish Palatinate, Germany, 1697; d. New York, N.Y., July 28, 1746. He was brought to New York City as an immigrant in 1710 and apprenticed to the colonial printer William Bradford from 1711 to 1719. After seeking business opportunities elsewhere and settling temporarily in Maryland, he returned to New York, became a freeman of the city in 1723, and joined Brad-

ford in a brief partnership in 1725. The following year he set up his own printing shop, supported largely by Dutch-language work and controversial matter which Bradford, as official printer for the provincial government, could hardly accept.

By the early 1730's Zenger's services were in special demand. A strong antiadministration popular party had been organized to oppose and expose the unscrupulous activities of a new and grossly incompetent governor, Col. William Cosby. The party leaders—notably the brilliant lawyer and journalist James Alexander (q.v.) and former chief justice Lewis Morris, whom Cosby had removed from office—engaged Zenger to print the *New-York Weekly Journal* in opposition to the government-controlled *New York Gazette*, published by Bradford. The first issue of the *Weekly Journal* appeared Nov. 5, 1733. Zenger assumed full responsibility as publisher, and all contributors were anonymous. Alexander apparently wrote and edited most of the articles, satirical advertisements, and other items printed.

The governor was unable to secure a grand jury indictment against the printer but finally had a warrant for arrest issued through the executive council. Zenger was imprisoned on Nov. 17, 1734, charged with seditious libel, and held under excessive bail for almost nine months; but professing "the liberty of speaking through the hole of the door to my wife and servants," he continued to issue his paper. At the trial that followed he was acquitted, and he eventually became public printer for both New York and New Jersey. After his death the *Weekly Journal* was continued by his wife until 1748 and by his son John Zenger until 1751.

Zenger had limited command of the English language, but he was a courageous printer and patriot. His ultimate fame as a defender and symbol of freedom of the press owes much to the greatness and eloquence of such men as James Alexander and Andrew Hamilton, who were responsible, respectively, for the success of his journal as well as his trial.

THE ZENGER TRIAL

The Zenger case was the most important trial for seditious libel during the colonial period in America. When it was brought to the attention of the court in April 1735, his lawyers, James Alexander and William Smith, questioned the right of the Cosby-appointed chief justice and his associate to preside over the case. As a result they were debarred, and John Chambers was named counsel for the defense. The trial was set for Aug. 4, 1735, and an acceptable jury was finally selected despite illegal maneuvering by the governor's faction. The attorney general and chief justice were thrown off guard completely, however, when Andrew Hamilton, a distinguished attorney from Philadelphia, stepped from among the spectators to take over as counsel for the defense.

Hamilton introduced a completely new approach to the issue, admitting the publication of the alleged libels but denying that they were false and defending the right of publication of matters "supported with truth." To accept this challenge the chief justice would have faced a public review of the governor's activities. Instead he insisted that the jury was required to determine only the fact of publication and that the court would decide the question of libel. Hamil-

ton had no other recourse than to turn to the jury and inform them, despite the explicit instructions of the chief justice, that it was their right to "determine both the law and the fact": whether there was "falsehood in Mr. Zenger's papers" and whether he was guilty of libel. In his eloquent peroration Hamilton made clear that the "liberties of their country" were at stake since "a bad precedent in one government is soon set up for an authority in another"; and he called on the jury to secure "that to which nature and the laws of our country have given us a right—the liberty of both exposing and opposing arbitrary power (in these parts of the world at least) by speaking and writing truth."

The decision of the jury was "not guilty," and Zenger was released the following day. The next year he published *A Brief Narrative of the Case and Trial of John Peter Zenger*, prepared by James Alexander. In 1953 a John Peter Zenger Memorial Room was established in New York City as part of the Federal Hall Memorial Museum on Pine Street. In retrospect the wisdom and foresight of Andrew Hamilton's defense are even more remarkable in view of the fact that truth as a defense against criminal libel was not generally guaranteed by constitutional law in the United States and Great Britain before the 19th century. Today it is a basic principle of freedom of the press.

ZENITH, zē'nith, an astronomical term of Arabic origin, designating the point directly overhead on the celestial sphere. The direction of the *astronomical zenith* is given by the extension of a plumb line; it is therefore affected by local deviations of the vertical caused by the earth's rotation and by uneven distribution of masses in the surrounding terrain. The zenith distance of a celestial object, the complement of its altitude, is its angular distance from the zenith, measured by the arc of a vertical circle which intersects the object and the zenith. The *geocentric zenith* is obtained by extending the line passing through the earth's center and the observer; its position differs somewhat from that of the astronomical zenith because it is independent of local deviations of the vertical and because the earth is not strictly spherical. The point underfoot diametrically opposite the zenith is called the *nadir*.

ZENITH TELESCOPE, an instrument used both in field astronomy and at fixed observatories for the accurate determination of latitude. The instrument consists essentially of a telescope mounted at its middle on one end of a counterweighted horizontal axis, which in turn is pivoted at its middle on a vertical pillar, permitting the axis to revolve in azimuth, or around the horizon. The telescope itself can rotate in a vertical plane at the end of the axis, and a circle attached to the axis permits it to be pointed to any al-

The Bettmann Archive

The Zenger trial in New York City in 1735 helped set the precedent for freedom of the press.

titude or zenith distance (the complement of the altitude). A very sensitive level is also attached.

The instrument is used in the following manner. The approximate latitude of the place must be known, either from a sextant or from some other type of observation. Two stars, whose declinations are accurately known, are chosen so that one crosses the meridian about as far north of the zenith as the other does south. Their right ascensions should not differ by more than 15 minutes. Their actual zenith distances will then be $Z_1 = \delta_1 - \phi$ and $Z_2 = \phi - \delta_2$ respectively, where δ_1 is the declination of the northern star, δ_2 that of the southern star, and ϕ the desired latitude. The telescope is then set and clamped at such a zenith distance that both stars will cross its field not more than about half a radius from the central horizontal wire. As it crosses the meridian, the distance of the first star from the central wire is measured with a filar micrometer. Without disturbing the angle the telescope makes with the vertical, it is then rotated 180° and the second star is similarly observed. Combining the two equations, we then get

$$\phi = \frac{1}{2} (\delta_1 + \delta_2) + \frac{1}{2} (Z_2 - Z_1).$$

The declinations are known from the star catalogs; the zenith distances have just been determined; hence we solve at once for ϕ , the latitude. Since refraction errors become greater at large zenith distances, the method is most accurate for stars within $15^\circ \pm$ of the zenith, while 30° is about the limit. Known as the Horrebow-Talcott method, it was first practically employed in 1832-1836 by Capt. Andrew Talcott of the United States Engineers in the Ohio-Michigan state boundary survey.

A zenith telescope in which the whole instrument floats in a basin of mercury has been devised by B. Cookson and used at the Royal Greenwich Observatory. The observations are made photographically by allowing the stars to trail across the field. The reductions are of the same type as with the visual type of instrument. Older methods of latitude determination, which employed the prime vertical instrument or zenith tube, are no longer in general use; the photographic zenith tube has largely superseded the zenith tube.

ZENJAN, zĕn-jān', or **ZINJAN**, zĭn-jān', or **ZANJAN**, zān-jān', city, Iran, on the Senjan River, 180 miles northwest of Teheran, in the First Ostan (Gilan). Once important as the principal center of the former Khamseh Province, it is now primarily an agricultural market (fruit, wheat), with some manufacture of cutlery, rugs, and cotton goods. It is situated on a railroad and has an airfield. The population is largely Turkic. Pop. (1956) 47,159.

ZENO, zĕ'nō, or **ZENON**, zĕ'nōn, Byzantine emperor: b. Rousoumblada, Isauria, Asia Minor, 426; d. Constantinople (now Istanbul, Turkey), April 9, 491. An Isaurian chieftain, originally called Tarasicodissa, he changed his name to Zeno about 467 on his political marriage to Ariadne, daughter of Emperor Leo I. In 469 the emperor appointed him master of the soldiers in the Orient (commander of the armies in western Asia) and consul. He usurped the throne in 474 at the death of Leo's infant grandson, Leo II.

The Mansell Collection

Ancient bust of the Byzantine emperor Zeno.

Zeno's reign was marked by internal commotions and foreign wars. For 20 months during 475-477 he was deprived of rule by Basiliscus, a usurper. In 478 he bribed Ostrogothic invaders of the empire to withdraw. In 479 he quelled a revolt in Constantinople by buying off the troops of its leader, his brother-in-law Marcian, and again purchased peace from the Ostrogoths, who had marched upon the capital at news of the uprising. Zeno repelled a third incursion of Ostrogoths in 481 by bribing Theodoric the Great, their king and the future ruler of Italy. From 484 to 488 the emperor withstood another revolt, headed by Illus, his master of the offices. Toward the end of this rebellion Zeno persuaded Theodoric, who was about to aid Illus, to invade Italy (488) and oust Odoacer (Odovacar), who had deposed the last Western Roman emperor, Romulus Augustulus, in 476 and was governing Italy—nominally as vice regent of the Eastern Roman emperor.

In ecclesiastical affairs Zeno was noted for his publication of the *Henoticon*, or *Decree of Union*, in 482. This formula reconciled the

moderate Monophysites (q.v.) with the orthodox Eastern Christians, but its issuance inaugurated the first important schism (484-518) between the Greek and the Roman churches.

ZENO, dzā'nō, **Apostolo**, Italian dramatist, critic, and literary historian: b. Venice, Italy, Dec. 11, 1668; d. there, Nov. 11, 1750. He was a co-founder (1710) of the critical periodical *Giornale dei letterati d'Italia* and court poet and historiographer to the Holy Roman emperor Charles VI at Vienna (1718-1729). Zeno's operatic librettos attained high literary quality, inspiring the efforts of such composers as Alessandro Scarlatti, Antonio Vivaldi, and Giovanni Battista Pergolesi. For many years he was Italy's leading dramatic poet. Since his death, even greater importance has been assigned to his scholarship and criticism, which includes biographical prefaces to several editions of the works of other Italian writers.

ZENO, Niccolò and Antonio, Venetian navigators: fl. late 14th century. Knowledge of the adventures of these two brothers derives mainly from a narrative purported to be based on their letters but first published in Venice in 1558, more than 150 years after the letters were written. According to the narrative, which has been doubted by most historians, the brothers entered the service of Henry Sinclair, Scottish earl of Orkney, about 1390. In 1393 or 1394 Niccolò is said to have sailed from the islands north of Scotland to the east coast of Greenland, where he visited a monastery; he died a year later, at Orkney.

About 1398 Antonio Zeno supposedly accompanied Sinclair on a westward voyage inspired by the reports of a fisherman who claimed he had spent several years in "Estotiland," somewhere southwest of Greenland. The informant pictured the country as abounding in gold and inhabited by "very intelligent people." Sinclair's expedition is said to have reached harbor in a new land which may have been Nova Scotia. Antonio soon returned, while Sinclair remained to explore the territory and to produce detailed descriptions of it, since lost. Antonio died in Venice about 1406. The 1558 account of this purported pre-Columbian discovery of the New World included an extremely inaccurate map of the North Atlantic, which confused mariners and geographers for more than a century.

ZENO OF CITIUM, zĕ'nō, sĭsh'ĕ-əm, Greek philosopher: b. Citiium, Cyprus, c. 335 B.C.; d. Athens, Greece, c. 263 B.C. Probably of Phoenician origin, he was shipwrecked near Piraeus, the port of Athens, in 313 and then settled at Athens. After attending lectures by leading professors of the several Athenian philosophical schools and studying their doctrines, he began about 300 to teach his own tenets in a public hall, the Stoa Poikile (Painted Porch), whence his system was named Stoicism. Zeno's presentation was so popular that he soon attracted many auditors, and he continued to teach there for almost 40 years, until his death. Zeno's exemplary life was so esteemed by the Athenians that they offered him citizenship, which he declined from fidelity to his birthplace. Another admirer, Antigonus II Gonatas, king of Macedon

(c. 276–239 B.C.), invited him to transfer his activity to the Macedonian capital (Pella), a request that Zeno refused.

Zeno propagated his doctrine also in numerous treatises, of which only brief and isolated excerpts are extant. Among his works are recorded: *On Life According to Nature*, *On Human Nature*, *On Emotions*, *On Duty*, *On Law*, *On Vision*, *On the Whole World*, *On Signs*, *On Varieties of Style*, *Ethics*, *Pythagorean Questions*, *Rhetoric Universals*, and *The State*. Besides these, he wrote on education and poetry and left memoirs.

Teachings.—Reconstruction of what Zeno taught is extremely difficult for two reasons: (1) so little of his literary production exists that only an imperfect and partial idea of his doctrine can be constructed; and (2) his successors' literary activity during the century after his death, in controversy with competing scholars of other schools, so obscured his original work that it can be determined only generally or by conjecture how Zeno gradually achieved the original outlines of Stoicism or how far he himself carried the school's solution of philosophical problems. Most of the extant definition, amplification, modification, and contradiction in Stoicism must be post-Zenonic, since Stoicism passed through three phases (early, middle, late) in its vigorous history from 300 B.C. to 200 A.D. After this the Stoic school ceased to exist as such; but having spread beyond the professional philosophers, it influenced the formation of the philosophy of the early Christian church fathers.

Zeno created a tripartite system divided into: (1) logic, including psychology and epistemology; (2) physics, including ontology and theology; and (3) ethics, including aesthetics and politics. He adapted his logic from the Cynic dogma of Antisthenes (c. 455–c. 360 B.C.) and the Megaric doctrine of Diodorus Cronus (fl. 300 B.C.); borrowed his physics mostly from Heraclitus (fl. 500 B.C.) and partly from Aristotle (384–322 B.C.); and acquired much of his ethics from the Cynics (q.v.). In his and his immediate successors' hands ethical doctrine so overshadowed logic and physics that it became the characteristic hallmark of Stoicism in antiquity and has persisted to the present as the most prominent part of the Stoic system.

Zeno's ethical teaching appears to have been based on the axioms: (1) that absolute law admitting no exception governs nature; and (2) that man's essential nature is reason. To the rational being the same act is both according to nature and according to reason; hence man must live according to nature, that is, according to his whole nature and not according to a part of it. As virtue is the life according to reason, so morality is simply rational action; passion and emotion are essentially irrational and must be extirpated. Virtue is the only good, vice is the only evil, everything else—poverty or wealth, health or pain, life or death—is indifferent. All virtues are equally good, and all vices are equally evil—there are no degrees: one is either wholly virtuous or wholly vicious. This celebrated paradox is qualified by the profession that the prime virtue is wisdom, whence evolve all other virtues. The wise man is the good man, good not for the sake of pleasure, but of duty; and being secure in his virtue, he is happy.

ZENO OF ELEA, zē'nō, ē'lē-ə, Greek philosopher: b. Elea (Velia), Italy, c. 490 B.C.; d. there, c. 430 B.C. He was a favorite pupil and friend of Parmenides (q.v.), whose doctrines he defended and whose political schemes he shared. About 450 B.C. Zeno accompanied his mentor to Athens, where he propounded the principles of the Eleatic school (q.v.), of which he was one of the last important exponents. He soon returned to Elea, where he later died in an attempt to oust the city's tyrant.

Of Zeno's philosophical treatises, only rare fragments remain in ancient authors' works, from which can be constructed something of his system. To support Parmenidean ontology, he proposed certain ideas about time and space. Since Parmenides had taught that the phenomenal world is illusory and false, that its essentials are alteration and multiplicity, and that true being has in it no plurality and is unchangeable, Zeno argued against multiplicity and motion and attempted to prove these to be impossible by showing that contradictory propositions follow from the assumption that they are real.

Zeno's argument against multiplicity may be summarized thus: (1) if the many exists, it must be both infinitely large and infinitely small; and (2) it must be both limited and unlimited in number. Of this fourfold argument against motion two illustrations are famous: (1) Achilles and the tortoise; (2) the flying arrow. The first assumes that Achilles, the swiftest of mortals, and the tortoise, notoriously a slow-moving reptile, run a race, in which the tortoise is given a start. Achilles never can overtake the tortoise because, when he has run to the point from which the tortoise started, he finds that the tortoise has advanced. Achilles then must run to the second point, only to find that the tortoise has reached a third point. This situation continues forever; although the interval continually diminishes, it never is eradicated entirely, and Achilles never will outrun the tortoise. This argument depends on a clear distinction between the measure of an interval and the number of points contained therein—a distinction that has been fully understood only in the 20th century.

The argument illustrated by the flying arrow states that an object cannot occupy two places at the same time. Therefore, at any particular moment during its flight the arrow is in only one place. But to be in one place is to be at rest. Therefore, the arrow is at rest at every moment of its flight. It follows that motion is impossible. This argument was not refuted until the 19th century, by application of the theory of assemblages and the theory of the functions of the real variable, which clarify the nature of space-time continua and of continuous functions.

Zeno's type of argument may be called the antinomy of infinite divisibility and is part of

his dialectic, which, according to Aristotle, Zeno invented. Certainly the conception of dialectic was as important in Zeno's system as it proved to be later in the philosophy of Plato, Kant, Hegel, Henri Bergson, and Einstein, who, among others, examined the essential contradictions inherent in our ideas of space and time. Zeno's merit was that by his illustrations he was the first to pose this important problem for later philosophy.

ZENO OF SIDON, zē'nō, sī'dən, Greek philosopher: b. Sidon, Phoenicia (now Lebanon), c. 150 B.C.; d. probably at Athens, Greece, after 73 B.C. He directed the Epicurean school at Athens after 100 B.C. and is known chiefly from the philosophical dialogues of Marcus Tullius Cicero, who attended his lectures there in 79-78 B.C. In book 1 of *De natura deorum*, Cicero declares that Zeno's clear, cogent, and elegant style was misapplied to so trivial and stupid a set of tenets as those of Epicureanism (q.v.). Zeno himself was noted for his scornful abuse of other philosophers; Cicero quotes him as calling Socrates an Attic buffoon, despite Socrates' position as the first Greek to apply critical and philosophical thought to moral problems.

Zeno held (1) that happiness lies in the enjoyment of present pleasure and the assurance that such enjoyment will last throughout life or most of life without the intervention of pain; (2) that if pain intervenes it will be brief, if extreme, or will have more pleasure than ill in it, if prolonged; and (3) that reflection on these principles will make men happy, particularly if they have been content with previously enjoyed good things and dread neither death nor gods (Cicero, *Tusculanae disputationes*, book 3). Of Zeno's voluminous writings, only a few fragments like these remain. Posidonius, the scientific historian, Zeno's younger contemporary, composed a treatise against him, which has perished.

ZENOBIA, zə-nō'bē-ə (Lat. SEPTIMIA, Aramaic BAT ZABBAI), queen of Palmyra: r. 267-272. She was one of the best-educated women of her age and an accomplished linguist; beyond this, little is known of her life before her marriage to Odenathus, who in 260 assumed the title of king of Palmyra (q.v.), a city at the northern edge of the Syrian Desert. To Zenobia's wisdom and courage are ascribed her husband's military successes against Persia from 262 to 267, when Odenathus, as a client king in command of Roman armies, preserved the Roman Empire's eastern frontier and even reconquered Mesopotamia for Rome.

On Odenathus' death, for which she was

probably responsible, Zenobia assumed the sovereignty in 267, styling herself queen, though nominally she acted as regent for their infant son, Septimius Vaballathus Athenodorus. At first she continued her husband's policy as defender of the empire and was prudent in administering the Palmyrene kingdom and in safeguarding Roman territory. But her ambition to reduce Rome's eastern provinces to her power soon caused her to embark upon the conquest of the Near East. She secured Syria in 268, occupied Egypt in 269, and in 270 overran nearly the whole of Asia Minor, where she established garrisons at strategic sites, all in professed protection of the imperial interests.

The Bettmann Archive

Zenobia, queen of Palmyra.

Success proved to be her ruin. Zenobia proclaimed Vaballathus emperor soon after Aurelian had been elected Roman emperor in 270, and the latter grew alarmed at her ambition. Marcus Aurelius Probus, Aurelian's general and future emperor, recovered Egypt. Aurelian personally reconquered Asia Minor and descended into Syria, where he defeated Zabdas, Zenobia's general, successively at Antioch (now Antakya, Turkey) and at Emesa (now Homs, Syria) in 271. He finally besieged Zenobia in Palmyra, which she defended bravely, but vainly. The city capitulated in 272 and was razed in 273.

Tradition tells that Aurelian captured Zenobia and Vaballathus in secret flight from the beleaguered capital and that when the Roman soldiers clamored for her death, she purchased her safety by sacrificing her ministers, among whom was Cassius Longinus (q.v.), the distinguished rhetorician, who had also been her tutor. Zenobia was taken to Rome in 274 to grace Aurelian's triumph, laden with costly gems, shackled hand and foot with gold fetters, and led by a gold chain. Through her conqueror's clemency, she was permitted to pass the rest of her life in retirement at a villa near Tibur (now Tivoli, Italy). Aurelian also pardoned her son and married her daughters into distinguished families.

Princeton University.

ZENODORUS, zē-nā-dōr'as, Greek sculptor. fl. 65 A.D. He was noted for two huge statues adorned with silver-chased decorations. The first portrayed the Roman god Mercury and required 10 years to complete. His second famous colossus was of the Roman emperor Nero, who commissioned it for his palace (the Golden House) in Rome. This gigantic statue, altered to represent Apollo, later was reset near the Flavian Amphitheater, which from that time on was called the Colosseum.

P. R. COLEMAN-NORTON,
Princeton University

ZENODOTUS, zē-nōd'ō-tas, Greek scholar: b. Ephesus, Lydia, Asia Minor; fl. c. 325 B.C. As the first superintendent of the Alexandrian Library, he classified Greek epic and lyric poetry and edited some of it. Particularly important were his editions of Homer's *Iliad* and *Odyssey*, each of which he divided into 24 books. In his recension Zenodotus emended the text by introducing new readings, transposing lines, inserting new verses, and branding some passages as spurious or dubious. He also compiled a glossary on Homer's vocabulary and a dictionary of foreign words in Greek. Zenodotus also edited Hesiod's *Theogony* and published studies of Pindar, some of which are still extant. He also may have written some epic poetry. Though some subsequent scholars have regarded his revision as rather subjective, Zenodotus remains a respected pioneer in ancient literary criticism.

ZENTA. See SENTA.

ZEOLITES, zē'ō-līts, hydrous aluminum silicates of sodium, potassium, calcium, and barium. Although differing in crystallization and composition, they have certain similar properties, and similar origins. Zeolites are three-dimensional

The alkali and alkaline-earth cations are replaceable. This feature has been made the basis of some household water softeners, in which hard water, containing calcium ions, is passed over a bed of granulated sodium zeolite. A calcium zeolite is formed, and the sodium ions enter the water. These replace the calcium ions and thus make the water "soft."

The zeolites are usually secondary minerals, resulting from the alteration of feldspars and feldspathoid minerals. In a few cases, they seem to be primary, having crystallized from a magma rich in alkalis and low in silica. Zeolites usually occur as fillings in cavities in basalts and other eruptive rocks.

The zeolites are comparatively soft, ranging from 3 to 5.5 in hardness. They are usually white or colorless, but may be colored yellow, brown, or red by impurities. The specific gravities are low, about 2 to 2.5. They are easily decomposed by acids, usually with gelatinization. They intumesce before the blowpipe.

The compositions may be variable, and in some cases are uncertain. Some of the more common zeolites are as follows:

Analcime— $\text{NaAlSi}_2\text{O}_6 \cdot \text{H}_2\text{O}$. Cubic; good crystals common, usually trapezohedrons. Hardness 5 to 5.5. Usually white or pinkish.

Chabazite— $(\text{Ca}, \text{Na}_2)\text{Al}_2\text{Si}_4\text{O}_{12} \cdot 6\text{H}_2\text{O}$. Hexagonal; cubelike rhombohedrons. Hardness 4.5. Commonly reddish or white.

Notrolite— $\text{Na}_2\text{Al}_2\text{Si}_3\text{O}_{10} \cdot 2\text{H}_2\text{O}$. Orthorhombic; nearly square prisms. Hardness 5 to 5.5. Usually white.

Thomsonite— $\text{NaCa}_2\text{Al}_2\text{Si}_2\text{O}_{20} \cdot 6\text{H}_2\text{O}$. Orthorhombic; usually in radiating fibers. Hardness 5 to 5.5. Takes a good polish and is used as a semiprecious gem.

Laumontite— $\text{CaAl}_2\text{Si}_4\text{O}_{12} \cdot 4\text{H}_2\text{O}$. Monoclinic. Usually pulverant after exposure.

Heulandite— $\text{CaAl}_2\text{Si}_4\text{O}_{12} \cdot 6\text{H}_2\text{O}$. Monoclinic; sometimes large. Conspicuous (010) cleavage. Hardness 3.5 to 4.

Stilbite— $\text{CaAl}_2\text{Si}_4\text{O}_{12} \cdot 7\text{H}_2\text{O}$. Monoclinic; usually in radiating sheaflike groups. Hardness 3.5 to 4.

Phillipsite— $\text{KCaAl}_2\text{Si}_4\text{O}_{16} \cdot 6\text{H}_2\text{O}$; and **harmotome**— $\text{BaAl}_2\text{Si}_4\text{O}_{16} \cdot 6\text{H}_2\text{O}$. Monoclinic; cruciform twins common. Hardness 4 to 4.5.

Some of the important localities for zeolites are Great Notch and West Paterson, N.J.; the copper district in the Upper Peninsula of Michigan; Bay of Fundy region, Nova Scotia; Faeroe Islands; the Harz Mountains and the Rhineland, Germany; Cyprus; Bombay and the Western Ghats range, India.

LEWIS S. RAMSDALL,
Professor of Mineralogy, University of Michigan.

The American Museum of Natural History
A radiating group of natrolite crystals.

silicates in which all four oxygen atoms in each SiO_4 group are shared by adjacent groups. Their structures have an open framework of $(\text{Si}, \text{Al}) \text{O}_4$, with the remaining cations and the H_2O in the openings. This structure results in two characteristic behaviors: (1) The water is easily and continuously lost upon heating, and regained by exposure to a moist atmosphere. It may also be replaced by other liquids, such as alcohol. (2)

ZEPHANIAH, zēf-an'ā (in Douay Bible SOPHONIAS), Old Testament prophet: fl. late 7th century B.C. Ascribed to him is the Book of Zephaniah, constituting three chapters of the so-called Book of the Twelve Prophets (or Books of the Minor Prophets) in the Old Testament. Zephaniah's lineage is traced back for four generations to King Hezekiah of Judah (r. about 715–687 B.C.). He was therefore a second cousin once removed of King Josiah (r. 640–609 B.C.), of whom he is believed to have been a contemporary (Zephaniah 1:1) and in whose training, under teachers influenced by 8th century prophets, he may have shared. However that may be, at least he was a citizen of Jerusalem who did not hesitate to criticize royalty while sparing the king himself; he shows less concern for the poorer part of the population; and his teaching fits the conditions of the 7th century immediately prior to the reform of Josiah in 621 B.C., so far as our meager information permits us to know them.

The evils mentioned in 1:4–5, 8–9, and 12 are

similar to those which, according to II Kings 21, were characteristic in Judah until Josiah was moved to action by the finding of the Code of Deuteronomy (621 B.C.). These included star worship, syncretism, foreign clothes and foreign religious practices, apostasy, and the denial of the Lord's activity. Moreover, it is possible that the stimulus to Zephaniah's preaching was given by the Scythian raids which Herodotus (*History*, book 1, chaps. 104–105), who is not always trustworthy, reports were made in this period. In the absence of strictly reliable data, we may tentatively conclude that a prince named Zephaniah delivered an oracle or oracles in the reign of Josiah, presumably about 625 B.C. Not all of the three chapters, however, are his; much of the prophecy probably originated some four centuries later. If the historical problems of Zephaniah could be solved, there would still remain the literary problems.

CHARLES L. TAYLOR.

ZEPHANIAH, Book of (in Douay Bible **PROPHECY OF SOPHONIAS**), a book of the Old Testament, attributed in part to Zephaniah (q.v.), a prophet of the late 7th century B.C. In the books of Isaiah, Ezekiel, and the Greek order of Jeremiah, the editors of the prophets show a well-defined pattern: first, denunciation of the people of Judah; then the turning of the divine wrath upon other nations; and finally, promises of prosperity to Judah while the heathen are converted or destroyed. This arrangement appears also in Zephaniah: chapter 1 condemns the sins of Jerusalem; chapter 2 (vss. 4–15) attacks the Philistines, Moabites, Ammonites, Ethiopians (or Egyptians), and Assyrians; chapter 3 (vss. 8–20) describes the gathering in of the exiles, the end of want and trouble, and the presence of the Lord among the remnant of His people. The remaining verses (2:1–3 and 3:1–7) may in part be derived from Zephaniah but contain doubtful features, especially the change from specific, indignant denunciation, which characterizes chapter 1 to the generalities of 2:3 or 3:4–5.

Even in chapter 1, there has been extensive editorial activity. The basis of this chapter is two poems: the first (contained in vss. 4–5, 8–9, and 12) is a declaration of the Lord's punishment of the Jerusalemites for specific sins that were rife in the 7th century B.C.; the second (in vss. 7, 10, 11, the first part of 13, and 14–16) is a description of the day of the Lord, not at the end of time, but near. Here there is no mention of the reasons for the disaster, but only, as in Isaiah 5:26–29 and 10:28–32, a statement of impending doom. When editors combined and interwove these two poems—or perhaps these portions of longer poems now mostly lost—there was ample opportunity for the introduction of quotation (compare the last part of 1:13 with Amos 5:11), for new emphases, and particularly for slight changes that make specific prophecy into vague eschatological predictions of a world catastrophe. Thus verses 2, 3, 17, and most of 18 in chapter 1 show how the day of the Lord close at hand, of which Zephaniah (like Amos before him) had spoken, became the day of universal cataclysm so characteristic of the apocalypses. While the possibility must remain open that one or the other of the two poems was not written by Zephaniah, the most likely hypothesis is that this royal personage delivered two oracles

which fortunately were preserved because of their connection with his name and upon which the rest of the book (in its present form dating perhaps from around 200 B.C.) could develop. The view that Zephaniah himself is "the first of our Old Testament writers whose mind is dominated entirely by eschatological ideas" (William O. E. Oesterley and Theodore H. Robinson, *An Introduction to the Books of the Old Testament*, New York 1934) is no longer generally accepted.

The contribution of Zephaniah is to be sought in his application of the teaching of the 8th century prophets (Amos, Hosea, Isaiah, and Micah)—that the Lord is offended by the conduct of His people—to the conditions of his own time. He was neither highly original nor an exceptional poet. Nevertheless, he has supplied literature with a memorable metaphor, "the men who are thickening upon their lees," and has provided art with the picture of the Lord searching Jerusalem with lamps (1:12; Revised Standard Version). If the teachings of 3:1–4 are his and may be added to those of 1:4–5, 8–9, 12, then his ire is particularly directed toward the oppressive, toward those who compromise with foreign worship and practice—the collaborationists of his day—and toward the indifferent, those who say in their hearts that the Lord does nothing, either helpful or hurtful, in the affairs of men (1:12). "God's causes," says George Adam Smith, "are never destroyed by being blown up, but by being sat upon" (*Book of the Twelve Prophets*, vol. 2, p. 52).

The description of the day of the Lord in 1:7, 10, 11, 13, 14–16 is not without power, and it inspired the *Dies Irae*, the medieval hymn attributed to Thomas of Celano. The Lord is pictured as on the point of offering Judah as a sacrifice, to which the enemy armies are invited as guests (1:7). Special emphasis is laid upon the immediacy of the event—the day of the Lord is at hand (1:7), near and hastening fast (1:14). As in Amos, that day is a day of darkness, not light, a day of distress and anguish, of ruin and devastation, of darkness and gloom, of clouds and thick darkness.

In the section on foreign nations (2:4–15) the religious teaching is not particularly significant; the underlying idea is that the proud will be overthrown and the humble exalted. In chapter 3, however, appears one of the inspiring promises of the eschatologists, the dream of a universal language—a pure speech—so that all nations may be able to worship the Lord together "and serve him with one accord," literally, "with one shoulder" (3:9). And the picture of the humble, truthful, trustful remnant in 3:12–13 inspires successive generations of readers to rejoice at the change of fortune for Israel which the Lord continually accomplishes. Thus even in neglected, obscure, and seemingly unimportant corners of the Old Testament there are treasures of permanent worth.

ZEPHYRANTHES, zéf-ə-rān'thēz, the zephyr lily, a genus of some 55 species of bulbous plants of the amaryllis family, Amaryllidaceae, native of the tropical and warm-temperate regions of North and South America. The basal leaves are long and narrow; the solitary, showy flowers, borne on a hollow scape, are 2 to 4 inches long and tubular, with 6 spreading perianth segments which are yellow, white, rose colored, or purplish. Atamasco lily, *Zephyranthes Atamasco*, indigenous to damp woods and meadows of the southeastern United States, has white or purplish flowers. It blooms in spring, is often found in profusion, and is collected and sold commercially. *Z. candida*, a native of South America, occurs in several forms and is frequently cultivated, blooming in late summer and autumn. It has white or rose-tinted flowers.

EDWIN B. MATZKE.

ZEPHYRUS, zēf'ə-rəs, in Greek mythology, god of the west wind, son of Astraeus (Starry Man) and Eos (Dawn), and brother of Boreas (North Wind), Notus (South Wind), and Eurus (East Wind). His wives appear variously as (1) Chloris, goddess of flowers and fruits, by whom he fathered Carpus, god of fruits; (2) Iris, goddess of the rainbow; (3) one of the Hours, goddesses of the seasons; and (4) Podarge, a Harpy, by whom he sired Achilles' swift steeds. Zephyrus, a minor figure in several myths, is usually represented in art as a handsome winged youth, carrying flowers in a fold of his cloak. In Roman mythology Zephyrus becomes Favonius, and Chloris becomes Flora.

P. R. COLEMAN-NORTON.

ZEPPELIN, zēp'ə-līn, Ger. tsēp-ə-lēn', **COUNT Ferdinand von**, German airship builder: b. Constance (Konstanz), Germany, July 8, 1838; d. Charlottenburg, March 8, 1917. The son of a titled Württemberg court official, he attended the Ludwigsburg Military Academy and the University of Tübingen and received an army commission in 1859. In 1863 he went to the United States and served for a time with the Army of the Potomac in the American Civil War. Later he took part in an expedition to the headwaters of the Mississippi. While in Minnesota, he made his first balloon ascent. After his return to Europe, he fought for Württemberg against Prussia in the Seven Weeks' War (1866) and was a cavalry officer in the Franco-Prussian War (1870-1871). He had attained general's rank in the German Army when he was suddenly retired in 1891, at the age of 53. He at once decided to devote his time to the development of dirigible balloons.

Though his costly experiments had soon reduced him to poverty, imperial support and funds raised through public subscription enabled him to build a rigid airship and fly it (for 20 minutes) in 1900. By 1914 several of his dirigibles, called zeppelins, had made flights of more than 1,000 miles, but 13 had crashed. Zeppelins were used to bomb England early in World War I, but they were found vulnerable to both storms and gunfire. The most famous of the zeppelins, the Hindenburg, went down in flames in 1937. By the time of the count's death the greater

potential of the airplane as a means of flight was becoming apparent.

ZERAVSHAN RANGE, zə-ráf-shān', mountain range, USSR, a part of the Pamir-Alai system of Soviet Central Asia. It is situated in the Tadzhik and Uzbek SSR's, extending east-west along the south bank of the Zeravshan River and rising at some points as high as 18,000 feet. Mineral resources include coal, rare metals, and fluor spar. The mountains are crossed by an automobile road linking Tashkent and Dushanbe.

THEODORE SHABAD.

ZERAVSHAN RIVER, river, USSR, a right tributary of the Amu Darya in Soviet Central Asia. It is about 460 miles long, rising in the Zeravshan Glacier, 140 miles southeast of Tashkent, in the Pamir-Alai mountain system. The river flows for some distance in a narrow, deeply entrenched gorge between the Turkestan Range in the north and the Zeravshan Range in the south and passes the town of Pendzhikent. After a course of about 130 miles in the Tadzhik SSR, it enters the Uzbek SSR, where it waters the oases of Samarkand, Katta-Kurgan, and Bukhara before disappearing in the desert sands near the Amu Darya. The Zeravshan collects virtually all of its water in the high mountains of the Tadzhik SSR and supplies it for irrigation in the Uzbek SSR. The oases that depend on it for water are among densely populated and productive in Central Asia. A large storage reservoir near Katta-Kurgan is used for irrigation of the surrounding region. The Zeravshan is not navigable. Its lower course, between Bukhara and Samarkand, is paralleled by a section of the Trans-Caspian Railroad.

THEODORE SHABAD.

ZERBST, tsērpst, city, Germany, on the Nuthe River, a small tributary of the Elbe, 70 miles southwest of Berlin and 12 miles northwest of Dessau. The old town, once much admired for its stately buildings, was virtually destroyed by aerial bombardment in World War II; only a few towers, remnants of the ancient wall, and parts of the city gates survived. Zerbst is a trading center for cattle and vegetables, especially asparagus; it has several breweries and some manufacturing, including textiles, leather, thermometers, and musical instruments. It existed as early as 1007, when it was mentioned under the name Zirwisti. From 1603 to 1793 it was the capital of the principality of Anhalt-Zerbst. Catherine II the Great of Russia, born a princess of Anhalt-Zerbst, spent her childhood in the city. After World War II it was included in the German Democratic Republic (East Germany), from 1952 in Magdeburg District. Pop. (1981) 19,283.

ZERMATT, tsēr-mät', village, Switzerland, in Valais Canton, Visp District. It is situated at an elevation of over 5,300 feet, 22 miles southwest of Visp, at the foot of the Matterhorn (q.v.), and is the traditional base from which expeditions set out to scale that famous peak. The village is popular both as a summer resort and for winter sports. Pop. (1980) 3,548.

ZERMELO PARADOX, tsēr-mə-lō. (also called **BERTRAND RUSSELL PARADOX**), in logic, a problem formulated independently, about 1902-1903, by Ernst Friedrich Ferdinand Zermelo (1871-

1953) and Bertrand Russell (q.v.) It deals with collections (sets) of all sets of objects which are not members of themselves. Suppose that we have a set S : Is S a member of itself? In 1919 Bertrand Russell popularized this problem by posing the following paradox: There is a village barber who shaves all those residents of the village who do not shave themselves. Does this barber shave himself? If he does not shave himself, then he should shave himself. But if he shaves himself, then he must not shave himself. Another variant of this paradox is as follows: A man asserts that all persons of his nationality consistently lie. If all persons of his nationality are liars, is the man himself telling the truth or lying? Zermelo, a German mathematician, is known mainly for his contributions to the logical theory of the foundations of arithmetic and to set theory (see LOGIC—3. *Modern Deductive Logic*), not the least of these contributions being the paradox which bears his name.

ZERNIKE, tsér'nā-kê, Frits, Dutch physicist: b. Amsterdam, July 16, 1888; d. March 10, 1966. After showing early promise as a student, he was educated at universities in Amsterdam and Groningen. He joined the staff of Groningen University in 1913 as an assistant in astronomy to Professor J. C. Kapteyn, became professor of theoretical physics and mechanics in 1920, and remained with the university throughout his career.

In the 1920's he developed the Zernike galvanometer, which registers very weak electric currents and is now standard equipment in major laboratories. His spectroscopic studies led to his announcement in 1934 of a "phase contrast" method of detecting and compensating for the irregularities in the curved reflectors of astronomical telescopes. He had already applied the basic principles of this technique to microscopy also, but its practical aspects were not at once perceived, and the Zernike phase contrast microscope came into general use only after World War II.

The phase contrast (or phase) microscope makes it possible to study minute transparent cells of living matter without first staining them chemically. Since such staining usually kills the specimens, the instrument has been of great value in biological and medical investigation, particularly in cancer research. It is equipped with an annular light-controlling diaphragm and a transparent "phase plate" with an annular coating or groove. The plate produces a phase difference of about one-quarter wavelength between the direct and the diffracted light waves that pass through it. This, together with diffraction index variations in the cellular matter under observation, effects an apparent "coloring" of the cells and makes their structures visible as lighter or darker details. Phase contrast microscopy thus is an important forerunner of holography. The Nobel prize for physics for 1953 was awarded to Zernike for his invention of phase contrast. He also developed a "color phase" microscopic process and did important work in chemistry, thermodynamics, and mathematical theory.

ZERO, zir'ô; the symbol "0" (or naught), as used in the Arabic system of numerals, and wherever that system is applicable. The standard use of zero is to indicate the absence of some

countable or measurable magnitude whose precise nature is determined by the context. Thus, in the numeral 205, the zero symbol indicates that the intended number is composed of 2 hundreds and 5 units, but no tens; "zero velocity" means no velocity, or rest; "zero degrees Centigrade" means a temperature that is no degrees above the arbitrarily chosen starting point of the thermometric scale, which is a temperature equal to that of melting ice; and "zero degrees absolute" or "absolute zero" (q.v.) refers to the theoretical low point on the absolute temperature scale, that is, a temperature at which it was once assumed there would be no molecular motion whatsoever. As a rule of thumb, "0" or "zero" may be replaced by the adjective "no," in the manner illustrated by the examples given. Like other adjectives, "zero" needs to be attached to a noun or noun clause whose reference it modifies.

The word "zero" is derived from the Arabic *sifr* ("something empty"—compare the related word "cipher"). The use of zero as a visible mark of absence was a striking innovation of the Arabic notation that reached Europe in the 12th century. In Greek and Roman arithmetic, the ambiguity resulting from the absence of a zero symbol was a serious hindrance to scientific progress. Familiar though it is, the use of zero must be reckoned as one of the basic intellectual inventions of modern culture.

An obvious way to indicate absence is by means of a blank space. But such a notation as 2 5, with a mere gap between the 2 and the 5, is easily confused with an error in transcription and fails to indicate what and how much is intended to be omitted; hence the early use of a dot, as in 2.5, to mark the gap. Our present oval sign 0 seems to have evolved from the hexagonal or other closed line originally drawn around the dot as a precaution against ambiguity or forgery. In this way, an auxiliary device for showing mere absence took on the appearance of a substantial symbol, apparently standing for a genuine number on a par with the so-called natural numbers 1, 2, 3, 4, 5, 6, 7, 8, 9.

Considered as a number, zero seems to have odd and mysterious properties that set it apart from the natural numbers. Plausible though it is for the addition of zero to make no difference (on the principle that nothing is being added), the parallel for multiplication by zero has to be rejected. The prohibition of division by zero seems reasonable, but the learner finds it hard to attach clear meaning to the symbol x^0 (x to the power zero) and is puzzled by the supposed demonstration that the value of x^0 is always 1. The truth is that such symbols as x^0 and $0!$ (factorial zero) have to be given stipulated definitions that are not derivable from any natural equation of "zero" with "no" or with "nothing."

In modern logic, 0 is sometimes treated as a device for mentioning classes that are null or empty. Thus, to say "There are zero pigs that can fly" is equivalent to saying "The class of pigs that can fly is null," and that in turn means the same as "There are no pigs that can fly." On this conception, 0 does not stand for some peculiar or mysterious entity, though it does have specifiable uses. In practice, however, the mathematician ignores the problem of a logical definition of zero and is content to treat 0 as a symbol sufficiently defined for his purposes by such a familiar rule of use as $0 + n = n$.

Although 0 has no reference in isolation, a temptation remains to treat words like "zero," "no," "nothing," and "nobody" as standing for extraordinary entities having a shadowy kind of existence. An ancient example is found in the sect called Neminians, established by one Radulfus at the end of the 13th century, who worshiped Nemo (that is, Nobody), the supposed person referred to by that name in biblical and classical texts. Similar tendencies may be detected in the preoccupation of some modern existentialists such as Germany's Martin Heidegger with "Nothing" and the alleged "encounter with Nothingness."

MAX BLACK
Cornell University

ZERO-POINT ENERGY, the kinetic energy remaining in a substance at the temperature of absolute zero; that is, at 0° K or -460° F (see ABSOLUTE ZERO). In many elementary science textbooks it is stated that the absolute zero of temperature would be characterized by complete absence of motion and energy. Although this temperature has not been, and may never be, attained, quantum mechanics, in particular the Schrödinger equation, has shown these statements in regard to the absence of motion and energy to be incorrect. Consider a simple harmonic oscillator, the behavior of which is approximated by a vibrating atom in an isolated molecule or in a solid. The Schrödinger equation gives for the energy of such an oscillator at absolute zero the value $\frac{1}{2}hf$, where f is the frequency of oscillation and h is Planck's constant (6.62×10^{-27} erg-seconds). The energy $\frac{1}{2}hf$ is the zero-point energy, and it cannot be further reduced.

The existence of the zero-point energy has been experimentally confirmed by analyses of molecular spectra and by the thermal behavior of gases at low temperatures. The vibrating atoms in a crystalline solid would have considerable energy in this lowest allowed state of vibration, and the zero-point energy accounts for the strange behavior of liquid helium at temperatures near absolute zero. The concept of zero-point energy satisfies the Heisenberg uncertainty principle, which forbids a particle ever to be completely at rest at a precisely known point.

ZERUBBABEL, zə-rüb'ə-bəl, governor of Judaea: fl. late 6th century B.C. The son of Shealtiel, governor of Judah (Haggai 1:1), and a grandson of the captive king Jehoiachin (I Chronicles 3:17), he was a recognized prince of Judah and led the first band of Israelitish exiles returning from Babylon. He was made governor of Judaea and, with Joshua, the high priest, directed the renewal of public daily worship and the reconstruction of the Temple, which was completed only after a 17-year interruption caused by their enemies.

ZETA RIVER, zē'tā, river, Yugoslavia, in the republic of Montenegro. It is a tributary of the Morača (which in turn flows into Lake Scutari), which the Zeta joins near Titograd after a southeasterly course of about 50 miles (80 kilometers) from its double source in the Dinaric Alps. It flows underground for some distance below the city of Nikšić. The last 15 to 20 miles (24 to 32 kilometers) of its course lie in the Bjelopavlići, a broad plain which is one of Montenegro's few fertile lowlands.

ZETKIN, tsēt'kën, Clara, German Communist leader: b. Wiederau, Saxony, July 5, 1857; d. Arkhangelskoye, near Moscow, USSR, June 20, 1933. Originally a schoolteacher, she joined the German Social Democratic Party and became its outstanding spokesman on women's rights, editing the paper *Die Gleichheit* from 1892 to 1916. She opposed the party's compromising position during World War I and in 1919 joined in forming the Communist Party in Germany. From 1920 to 1933 she was a Communist deputy in the Reichstag, although she had differences during much of this period with the Soviet leadership. She published a number of books on women's problems. Her *Reminiscences of Lenin* appeared in English translation in 1929. She was known as an impassioned orator.

ZETLAND. See SHETLAND ISLANDS.

ZEUGLONDON, zōō'glə-dŏn, the popular name of the gigantic fossil whale *Basilosaurus* of the primitive cetacean suborder Archaeoceti. *Basilosaurus* is known from late Eocene deposits in the southeastern United States. Its closest relatives have been found in the late Eocene of Egypt and in the early Oligocene of the Ukraine. *Basilosaurus* and its close allies are the largest archaeocetes, reaching a length of 65 feet. The skull alone may extend 5 feet. The neck is short, but the succeeding vertebrae are elongate. The bones of the rostrum and cranium are not telescoped together as in more-advanced cetaceans. Serrate teeth are present. The anterior limbs were still functional and served as paddles, but the rear limbs are greatly reduced and are contained within the body. Traces of the pelvis and femur have been found. Zeuglodon and the other primitive whales are believed to have originated from primitive terrestrial carnivores.

MALCOLM C. MCKENNA
American Museum of Natural History

ZEUS, zōōs, in ancient Greek religion, the chief deity. He was known to the Romans as Jupiter (Juppiter) and to Asiatic Indians as Dyaus pita. In origin he was an Indo-European divinity—a weather god enthroned on mountain summits, which are watched for indications of weather, and the ruler of the sky (the name means "sky"), where atmospheric phenomena are observed. As god of the bright sky, he controlled the sun, moon, stars, and planets; as god of the dark sky, he caused thunder, lightning, clouds, winds, dew, rain, hail, sleet, snow, comets, meteors, and meteorites.

Zeus was the son of Cronus (Kronos) and Rhea, and brother of Hestia, Demeter, Hera, Hades, and Poseidon. He married successively Metis (Counsel), Themis (Law), and Hera (Lady), of whom the last was his sister. By more than 115 mistresses, both mortal and immortal, he had over 140 offspring, such as the Graces, the Muses, the Seasons, and numerous kings and queens, heroes and heroines, who were considered demideities. His divine children, who ranked as Olympian divinities (except Persephone), were Apollo, Ares, Artemis, Athena, Dionysus, Hebe, Hephaestus, and Hermes.

Epithets. Homer, the earliest Greek writer to mention Zeus, calls him "father of gods and men," a designation to be interpreted as signifying a paterfamilias, the father of a family, whose members owe obedience to him as director

of their conduct and upholder of customary law. From this conception came several of his more than 685 recorded epithets, such as *Ktesios* (protector of the household), *Herkios* (defender of the courtyard), *Hikesios* (supporter of suppliants), and *Xenios* (upholder of hospitality). Since the family was the foundation of the state, it was a short step to associate Zeus with care of the city-state; hence political epithets, such as *Polteus* (guardian of the city), *Eleutheros* (vindicator of liberty), *Agoraios* (advocate of the assembly), and *Boulaios* (champion of the council). From his role as overseer of the state developed his role as observer of conditions among mortals; hence moral epithets, such as *Epopsios* (observer of all things), in which capacity he castigated criminals and avenged injured persons, and *Horkios* (maintainer of oaths), in which role he punished those who violated the sanctity of their sworn pacts.

As *Panompaios* (author of all divination), Zeus was the primal source of prophetic power. As *Soter* (savior), he saved persons, particularly sailors and seafarers, from peril. Other epithets referred to the many places where Zeus was worshiped throughout the Hellenic world. Of these the most noted were *Diktaios* (of Mount Dikte in Crete, where he was born); *Lykaios* (of Mount Lykaion in Arcadia, where he was reared); *Olympios* (of Mount Olympus in Thessaly, where he dwelt); *Dodonaios* (of Dodona in Epirus, where his oracle was the oldest oracle in Greece); *Ammon* or *Ammonios* (of Ammonium, now the Oasis of Siwa, in Egypt, where Alexander the Great of Macedon was hailed in 332 B.C. as the son of Zeus Ammon by the priests of this oracular shrine); and *Olympikos* (of Olympia in Elis, where, from 776 B.C., the Olympic games were held quadrennially in his honor and where, in 457 B.C., Phidias completed his colossal statue of Zeus *Olympikos*, one of the Seven Wonders of the World, in the Olympeum or Temple of Zeus).

Mythology. Many important myths, with numerous variations, concerned Zeus. Cronus, his father, was destined to be overthrown by one of his sons and therefore customarily swallowed his newborn male children. Rhea, Cronus' sister-wife, consulted Uranus (Heaven) and Gaea or Ge (Earth), their parents, as to how the unborn Zeus might be saved. For her lying-in they sent her to Crete, where she bore Zeus, concealed him in a cave, and substituted a stone, wrapped in swaddling clothes, for Cronus to swallow. The infant Zeus was tended by nymphs and nourished on milk given by a goat and on honey gathered by bees. Weapon-clattering Curetes (semidivine beings) danced around him and by their noise prevented his father from hearing the babe's cries. After he had reached manhood, Zeus plotted with Poseidon and Hades whom Cronus had been persuaded by trickery to disgorge—to dethrone their father. This attempt induced war with the Titans, who supported their brother Cronus. Zeus received aid from the Cyclopes, whom he had liberated from the bonds put upon them by Cronus and who in gratitude armed their deliverer with thunderbolts. He also had the help of certain hundred-handed giants. With these allies he conquered the Titans and then imprisoned them with Cronus in Tartarus (Hell). Thus Zeus won domination of the world, which he then divided by lot with his brothers: Poseidon obtained the sea, Hades received the under-

world, Zeus secured the sky, while the earth was held as common property.

Above all, Zeus was the supreme ruler, the most powerful among the immortals, the protector of regal power, the custodian of law, and the guardian of morality, his assistants being the goddesses Dike (Justice), Themis (Law), and Nemesis (Retribution). According to his own choice, he assigned a good or evil lot to mortals. He was armed with thunder and lightning; the shaking of his shield produced storm and tempest. The eagle, the oak, and the mountain peaks were sacred to him. His sacrifices usually were goats and cattle.

Artists normally portrayed Zeus as a muscular, majestic elder, with abundant locks and bushy beard, wearing a wreath of olive or oak leaves on his head, and holding in his hands various objects, such as a figure of Nike (Victory), a scepter, a cornucopia, and thunderbolts. He is often pictured with an eagle at his feet.

ZEUXIS, zōōk'sīs, Greek painter: b. Heraclea, Lucania, Italy; d. Ephesus, Lydia, Asia Minor; fl. 400 B.C. He either introduced or improved the use of highlights in shading. While he occasionally painted small subjects on clay plaques, his principal work was executed on walls and portrayed human figures in superhuman proportions. The chief criticism of his painting was that it emphasized form rather than character. His greatest fame came from his decoration of the Macedonian royal palace at Pella, where tourists went to admire his art. Like other painters of his period, Zeuxis specialized in mythological subjects, among which are recorded: *Zeus Enthroned amid Deities*; *Eros Crowned with Roses*; *The Centaur Family*; *The Infant Hercules Strangling the Serpents*; *Alcmena*; *Helen*; *Penelope*; *Pan*; *Autoboreas*; *The Muses*; *The Bound Marsyas*; and *The Weeping Menelaus*.

ZHAO Ziyang, jou' dzi'yang' (1919–), Chinese political leader, who became both chief of government and formal head of the Chinese Communist Party (CCP). Zhao was groomed for his job as premier by Deng Xiaoping, China's paramount leader, who had picked him to carry forward the nation's new program of economic modernization. Deng's choice rested on Zhao's record in Sichuan, where he had shown flexibility and innovativeness in converting the troubled economy of that province to one of the most productive in China.

Zhao Ziyang (Chao Tzu-yang) was born in Henan province in 1919. He joined the CCP in 1938, and before the Communist takeover in 1949 he was a county party secretary in Henan. Afterward he rose in the CCP hierarchy of Guangdong, becoming first secretary in 1965. Purged as a "capitalist roader" in 1967 during the Cultural Revolution, he was restored to his Guangdong post in 1972. In 1975 he became party leader in Sichuan, where he experimented with allowing factories greater freedom of management and with increasing the amount of privately cultivated land. By 1978 industrial production was up 81% and farm output 25%. The next year Zhao was elevated to the CCP's central Politburo, and early in 1980 to its Standing Committee, or inner circle. In the role of deputy premier that year, he in effect ran the government

for Premier Hua Guofeng, whom he succeeded in September.

As China's chief administrator, Zhao implemented Deng's policies of loosening state control of the economy, of providing greater incentives for managers, workers, and farmers, and of promoting foreign investment in China. At the same time, he worked closely with Deng's other chief deputy, CCP General Secretary Hu Yaobang, in campaigns against crime and official corruption. The two men were widely regarded as the "legs that Deng stood on." In 1987, Zhao succeeded Hu as general secretary. But in 1989, blamed for "supporting the turmoil" of student-led demonstrations for democracy, Zhao was dismissed from all posts that he held.

ZHDANOV, zhda'nôf, a city in the USSR, in Donetsk oblast, Ukrainian SSR, 60 miles (95 km) south of Donetsk. Zhdanov is a major port on the Sea of Azov, near the mouth of the Kalmius River, and the terminus of a railroad from the Donets Basin. The city is an important steel-producing center with three steel mills (the Azovstal, Ilyich, and Kuibyshev plants), using iron ore from Kerch and coking coal from the Donets Basin. Other industries include shipyards, chemicals, and machine building. The port, one of the largest in the Ukraine and in the entire Soviet Union, serves primarily the nearby Donets Basin. In addition to iron ore, incoming goods include manganese, timber, and manufactured and food products; outgoing commodities include coal, steel, machinery, and farm products. Zhdanov has a steel-engineering school and a regional museum. The city was founded by Crimean Greeks in the 1880's and named Mariupol. It had already developed as a port and a steel center before the Bolshevik Revolution, but its growth was speeded under the Soviet regime. In 1948 it was renamed for the Soviet political leader Andrei Aleksandrovich Zhdanov. Population: (1979 census) 503,000.

ZHITOMIR, zhi-tô'mēr, an oblast in the USSR, in the Ukrainian SSR, on the southern margins of the Pripyet Marshes, west of Kiev. More than four fifths of the oblast's area of 11,500 square miles (29,785 sq km) is typical of the marshlands, with gray-brown forest soils, large wooded areas, and much swampiness. Mineral resources are limited to peat, building stone, kaolin, sand, and other construction materials. The economy of the oblast is primarily agricultural, with flax, potatoes, and livestock predominating in the lower-lying marshlands, and sugar beets, wheat, corn, and livestock in the drier uplands. The area's principal cash crops are flax, sugar beets, and hops. In addition to food processing (dairying, meat-packing, sugar refining, alcohol distilling), industries include stonecutting and the manufacture of porcelain, glass, wood, and paper. Furniture and musical instruments are also made. The principal cities are Zhitomir (the capital), Berdichev, Korosten, and Novograd-Volynski. The oblast is inhabited mainly by Ukrainians, Russians, and Belorussians. There was a large Jewish population before the German invasion in World War II. The oblast was formed in 1937. Population: (1979 census) 1,597,000.

Author of *"Geography of the USSR"*

ZHITOMIR, zhi-tô'mēr, a city in the USSR, capital of Zhitomir oblast, Ukrainian SSR, 85 miles (135 km) west of Kiev, on the Teteriv River (a tributary of the Dnieper). Zhitomir is an industrial and transportation center of the western Ukraine, situated in a rich agricultural area at the junction of four railroads. Its industries include wood-working plants; manufactures of furniture, musical instruments, and building materials; hosiery and shoe factories; and a large food-processing industry (meat-packing, canned goods). It is also the chief Soviet processor of hops. Zhitomir is a cultural and educational center, with agricultural and teachers colleges and several higher trade schools. The city had a large Jewish population before it was occupied by Germany during World War II.

Zhitomir was founded in the 9th century under Kievan Russia. It was sacked by the Tatars in 1240 and passed to Lithuanian rule in the 15th century. By 1569 it became part of Poland and was annexed by Russia at the time of the second partition of Poland in 1793. In the 19th century it was the administrative capital of Volhynia and an active trading center for timber, grain, and hops. Population: (1979 census) 244,000.

ZHUKOV, zhōo'kôf, **Georgi Konstantinovich**, Soviet army officer: b. Kaluga Province, Russia, 1896; d. Moscow, June 18, 1974. The son of peasants, he became a private in the Imperial Russian Army in 1915. By 1917 he had advanced to sergeant and had twice been decorated with the Cross of St. George. After the Russian Revolution, he joined the Red Army (1918) and served throughout the civil war as an officer of cavalry. Zhukov attended the Frunze Military Academy (1928-1931) and thereafter became the commander successively of a cavalry regiment, a division (1934), and a corps (1936). During this period he was closely associated with Gen. (later Marshal) Semyon K. Timoshenko and took a leading part in the development of the Soviet Union's armored forces.

In January 1940, Zhukov was appointed chief of staff of the Soviet forces in the final stages of the Russo-Finnish War. He was promoted to army general in May 1940 and became chief of staff of the Red Army, vice commissar for defense, and an alternate member of the Politburo in January 1941. He was active in the sweeping reorganization and retraining of the Soviet Army that followed the Finnish war.

After Adolf Hitler invaded Russia in June 1941, Zhukov took part in defensive operations on the central and Leningrad fronts as representative of the High Command. In October 1941 he was appointed to command the reserve forces that were being massed for the defense of Moscow, and he brought the German offensive to a halt in December of that year. Meanwhile the Headquarters (Stavka) of the Supreme Command had been organized, and Zhukov became 1st deputy commissar for defense and—under Joseph Stalin's overall direction—the virtual chief of the Soviet war effort, aided by the 2d deputy commissar for defense, Gen. Aleksandr M. Vasilievsky. In 1942 he personally organized the great counteroffensive at Stalingrad and subsequently the operations that resulted in the relief of Leningrad; for these services he was promoted to the rank of marshal of the Soviet Union. His

Marshall Zhukov, a prominent Soviet military leader in World War II, at the Kremlin before a parade.

final front command of the war was the invasion of Germany and the great offensive against Berlin (1944–1945).

After World War II, Zhukov commanded the Soviet occupation forces in Germany (1945–1946) and in 1946 was recalled to Moscow as deputy minister of defense and commander in chief of the ground forces. A few weeks later he was relieved of these posts and ordered to an obscure command at Odessa, apparently because of Stalin's jealousy of his military reputation. Late in 1952, however, Zhukov was suddenly and secretly reinstated in both the posts from which he had been dismissed, for reasons never clearly revealed.

On the death of Stalin, in March 1953, he played a prominent part in the arrest and overthrow of Lavrenti P. Beria, the head of the secret police. The army now became a powerful political force, and in February 1955 army support headed by Zhukov was responsible for Nikita S. Khrushchev's political triumph over Georgi M. Malenkov, Zhukov becoming minister of defense.

In June 1957 the revolt of Vyacheslav M. Molotov and Malenkov against Khrushchev was crushed by Zhukov, who boldly told the Central Committee that the armed forces would not "permit anyone to bid for power." Zhukov was now made a full member of the party Presidium, the first Soviet professional soldier ever to reach the eminence. In October 1957, however, he was ousted from this and all other political positions and again relegated to obscurity, ostensibly for trying to limit the control of the party organization over the armed forces, but probably because Khrushchev had become suspicious of him.

After the ouster of Khrushchev in 1964, Zhukov was allowed to return to public life once again. He made appearances at military functions, and his wartime memoirs, *Toward Berlin*, were published in the official magazine of the Soviet ministry of defense.

GEORGE FIELDING ELIOT
1898–1957

ZIA-UL-HAQ, zē'oul-hāk', Muhammad (1924–1988), president of Pakistan. A military officer with no apparent political ambitions, he was chief of staff of the army in 1977 when he led a bloodless coup that deposed Prime Minister Zulfikar Ali Bhutto. General Zia then became chief martial-law administrator, and in 1978 he assumed the presidency.

Zia was born in Jullundur, eastern Punjab (now part of India), in 1924. Commissioned from the Royal Indian Military Academy, he moved to Pakistan upon its separation from India in 1947. Holding increasingly important military posts, Zia became a full general in 1976 and was named by Bhutto, over officers with greater seniority, as the army's chief of staff.

When Bhutto's party won an electoral landslide in March 1977, the opposition charged fraud. Widespread unrest brought hundreds of deaths. On July 5, Zia took control by military coup.

Subsequently, Zia failed to hold elections and step down as he had promised. He launched "Islamization" reforms. In 1979, Zia permitted the execution of Bhutto, denying him clemency after the Supreme Court upheld his conviction for complicity in a 1974 political murder. Thereafter, Zia suppressed all opposition.

Zia supported guerrillas fighting against the Soviet puppet regime in Afghanistan. He pressed for withdrawal of Soviet troops, an aim embodied in the U.N.-sponsored accords of early 1988. On August 17, 1988, as Soviet troops were withdrawing, Zia was killed when his plane exploded near Bahawalpur in eastern Pakistan.

ZIEGFELD, zig'feld, Florenz (1869–1932), American theatrical producer, who established a standard of taste and artistry that left its mark on stage entertainment. He was born on March 21, 1869, in Chicago, Ill., the son of the founder of the Chicago Musical College. He began his career in the entertainment field by importing bands for the Chicago World's Fair in 1893; he was also manager for the strong man Eugene Sandow. In 1896 he produced the play *A Parlor Match*, with Anna Held, a young actress from Paris, whom he married the next year. She appeared under his direction in shows featuring songs, settings, and costuming, which foreshadowed the musical revues that were Ziegfeld's distinctive contribution to the American stage.

The first of his revues was *The Follies of 1907*, followed by more than 20 consecutive annual editions of *The Ziegfeld Follies*, billed as "An American Institution." They were spectacular displays, combining lavish and imaginative sets and costumes with an abundance of attractive girls. Under the slogan "Glorifying the American Girl," Ziegfeld created a model of feminine beauty that became the fashion, emphasizing slenderness and grace. He hired leading composers, librettists, lyricists, and top-notch comedians for his shows.

Ziegfeld was an acute judge of talent and launched many stars of musical comedy and motion pictures on their careers, including Will Rogers, W. C. Fields, Eddie Cantor, Fanny Brice, Marilyn Miller, and Mae Murray.

Ziegfeld was prodigal with money in his personal and professional life. He sometimes discarded, after one performance, a scene on which he had spent huge sums.

Besides the *Follies*, his outstanding stage successes included *Sally* (1920), starring

© JONATHAN WRIGHT/BRUCE COLEMAN, INC.

The ziggurat was a Mesopotamian temple tower—either a simple platform (above, at Uruk) or a staged structure.

Marilyn Miller; *Kid Boots* (1923), with Eddie Cantor; *Rio Rita* (1927); *Show Boat* (1927); and *Bitter Sweet* (1929).

Ziegfeld's marriage to Anna Held ended in divorce, and in 1914 he married the actress Billie Burke. He died in Hollywood, Calif., on July 22, 1932.

ZIEGLER, tsē'glər, Karl (1898–1973), German chemist, who shared a Nobel Prize for his discoveries of catalysts for synthesizing plastics. Ziegler was born near Kassel, Germany, on Nov. 26, 1898. After receiving a doctorate from the University of Marburg, he taught at the universities of Heidelberg and Halle. In 1943 he accepted the directorship of the Kaiser Wilhelm (now Max Planck) Institute for Coal Research in Mülheim. By this time he was already renowned for his important discoveries in synthetic organic chemistry.

In the early postwar years Ziegler investigated catalytic polymerization reactions. In 1955 he announced the discovery of a variety of metallic and organometallic catalysts that enabled ethylene, propylene, and other olefins to polymerize at low pressures and with hitherto unequalled control over the precise shapes of the macromolecules. On the basis of Ziegler's research, the Italian chemist Giulio Natta developed commercial processes for new high-performance polyethylenes, polypropylenes, and polystyrenes. For the first time it became possible to synthesize a product virtually identical to natural rubber. For this work Ziegler and Natta shared a Nobel Prize in 1963. The new Ziegler-Natta catalysts revolutionized plastics technology, dramatically expanding the applications of these materials while lowering their price. Ziegler died in Mülheim on Aug. 11, 1973.

A. J. ROCKE, *Case Western Reserve University*

ZIGGURAT, zig'ə-rat, the temple tower which was the most characteristic feature of sacred architecture in Mesopotamia. In Assyrian the word was *ziquurratu*, from *zaqāru*, "to build high." Its significance is revealed in the Sumerian pictograph for "sanctuary": a house on a mountain.

The ziggurat was an artificial mountain, architectonically conceived and built with immense

communal effort high above the plain to support the sacred shrine destined principally for the descent and visitation of the deity. A monumental stairway led from the summit to a temple at ground level, where the image of the god symbolized his epiphany.

Ruins of more than 30 ziggurats are known from Mesopotamian sites. Every important city possessed at least one temple tower as an integral part of a temple complex dedicated to its principal divinity. The sanctuaries of the 4th and early 3d millennium B.C. were raised on simple platforms: square, as at Erech (Uruk), Brak, and Al 'Ubaid; or oval, as at Khafajah and Uqair. The earliest stepped ziggurats go back to the 3d dynasty of Ur, at the end of the 3d millennium B.C. Examples of these are at Eridu, Ur, Erech, and Nippur.

Two basic types of temple towers evolved: one rectangular, in Sumer (Eridu, Ur, Nippur), featuring a triple stairway; another, square in plan, in Assyria (Kār-Tukulti-Ninurta, Assur or Ashur, Calah or Kalakh). The latter date from the 13th to the 9th centuries B.C.; their means of access are nowhere preserved. The continuous square spiral ramp which led counterclockwise in seven turns to the summit at Khorsabad (ancient Dur Sharrukin, 8th century B.C.) was a new solution. It was copied (6th century B.C.) in the Neo-Babylonian Tower of Babel (Genesis 11:1–9). The Elamite ziggurat at Choga Zanbil (13th century B.C.) is the largest known (320 feet square) and the best preserved.

The huge core of the temple towers consisted of mud brick, often with layers of reed matting between. The masonry was reinforced by anchor chains and was protected by a thick encasement of baked brick laid in asphalt.

The ziggurats rose in three to seven stages, diminishing in area and height. Their walls, articulated by buttresses and sometimes differentiated by colors, believed to be of cosmological significance, sloped inward (Sumer) or were perpendicular (Assyria, Babylon). Plants on the terraces completed the image of the sacred mountain as the source of all life and seat of divine power.

PAUL LAMPL, *Author of "Cities and Planning in the Ancient Near East"*

ROBERT HARDING PICTURE LIBRARY LTD

Spacious Harare is the capital of Zimbabwe. The city was formerly named Salisbury.

ZIMBABWE, zim-bā'bwā, a landlocked republic in southeastern Africa. It is located on the southern African plateau, surrounded by Mozambique, Zambia, Botswana, and South Africa.

Zimbabwe became independent on April 18, 1980, after 14 years of guerrilla warfare waged by black nationalists. As Southern Rhodesia it had been ruled by whites, a minority who originally arrived in 1890 as settlers with Cecil Rhodes' British South Africa Company. Rhodes had intended to extend Britain's African empire from Cape Town to Cairo. Since 1890, Zimbabwe has been successively a territory under company charter, a self-governing British colony, an illegal independent state, a British colony again, and an independent nation under majority rule.

When the white settlers came, they took the best lands and forced the Africans onto overcrowded reserves, now known as communal lands. Africans fought the war of liberation to reclaim what had been theirs. Almost all aspects of the society are undergoing change as the independence government tries to redirect priorities to meet the needs of the African population. Its goals are to develop a nationwide education system and health service, to maintain security, and above all to provide access to land for the majority of the people without jeopardizing the nation's economic well-being.

Soon after independence, several years of drought and world recession strained the country's resources and the government's ability to transform the economic and social structures. But the pace of reform will probably be determined by political pressures, rather than economic considerations, as varying factions within the ruling party vie for dominance.

1. The Land

Zimbabwe extends about 500 miles (800 km) from east to west and 450 miles (720 km) from

north to south. The land rises in the north and northwest from the Zambezi River and in the south from the Limpopo River. In the east a mountainous area known as the Eastern Highlands edges the plateau, separating it from the plains of Mozambique. Here Zimbabwe's highest peak, Inyangani, rises to 8,503 feet (2,592 meters). In the southwest the plateau slopes gently toward Botswana and the edge of the Kalahari desert. Most of Zimbabwe is at least 2,950 feet (900 meters) above sea level. Running nearly 300 miles (480 km) from north to south almost through the middle of the country is the Great Dyke, a range of hills about 6 miles (10 km) wide that contains reserves of chrome ore, platinum, and gold.

The extensive river systems of the plateau drain north into the Zambezi and south into the Sabi-Lundi and Limpopo river basins. The riv-

INFORMATION HIGHLIGHTS

Official Name: Republic of Zimbabwe.
Name of Nationals: Zimbabweans.
Head of State: President.
Head of Government: Prime Minister.
Legislature: Parliament, consisting of the House of Assembly and the Senate.
Area: 150,803 square miles (390,580 sq km).
Boundaries: North, Zambia; east, Mozambique; south, South Africa; west, Botswana.
Elevations: Highest, Inyangani (8,503 feet, or 2,592 meters); lowest, junction of the Sabi and Lundi rivers (535 feet, or 163 meters).
Population: (1981 provisional census) 7,539,000; (1983 est.) 8,376,000.
Capital and Largest City: Harare.
Major Languages: English (official), Shona, Shindebele.
Major Religious Groups: Animists, Christians.
Monetary Unit: Zimbabwe dollar (= 100 cents).
Flag: Seven horizontal bands of green, gold, red, black, red, gold, and green; at left, a white triangle containing a gold Zimbabwe bird superimposed on a red star. See also FLAG.

ers empty into the Indian Ocean through Mozambique. None of Zimbabwe's rivers are regularly navigable. Along the northwestern border between Zimbabwe and Zambia is Lake Kariba, which covers more than 3,000 square miles (7,770 sq km). The lake was created in 1958-1959 when construction of Kariba Dam flooded part of the Zambezi Valley. "Operation Noah," the rescue of animals stricken by the flooding, received worldwide attention.

Although Zimbabwe lies wholly within the tropics, its high elevations provide moderate temperatures the year round. Moreover, the humidity is low. In summer the temperature averages between 77°F (25°C) and 86°F (30°C); in winter, from 59°F (15°C) to 68°F (20°C). The high plateau is subject to frost.

The rainy season runs from mid-November to the end of March, or late spring to early autumn. Farmers are highly dependent on rainfall, which is often capricious. In almost 30% of the country precipitation is too erratic even for drought-resistant crops. Prime growing areas are in the north central region and the Eastern Highlands, about 19% of the land. About 40% of the country receives more than 28 inches (700 mm) of rain annually, the minimum required for semi-intensive farming. In Matabeleland (the southwest) rainfall is low but sufficient for drought-resistant fodder crops for cattle.

Soils are predominantly sandy, and the land is dotted with granite outcroppings and boulders. The vegetation is savanna grassland on the central (high) plateau, with wooded savanna throughout the rest of the country. Most wildlife is found in the nation's game reserves, primarily at Hwange National Park, Gona Re Zhou Game Reserve, and along the Zambezi River. About 15% of Zimbabwe's territory is set aside as national lands.

In most of the country the high elevation minimizes the risk of contracting malaria, but preventive measures should be taken in the low-lying areas. The tsetse fly, species of which cause sleeping sickness in humans or diseases fatal to cattle, is prevalent in the Zambezi Valley and the extreme southeast.

2. The People

Provisional figures from the 1982 census give the population of Zimbabwe as 7,539,000. The average annual rate of natural growth for the 20-year period beginning in 1980 is projected at 4.4%, yielding a population of 16 million by 2000. Only Kenya has a higher growth rate.

Ethnolinguistic Groups. Africans constitute almost 99% of the population and speak Bantu languages. Nearly 82% of the Africans are Shona speakers, known as Mashona. Within this grouping are six major linguistic subgroups: the Karanga (22%) from the Masvingo area, the Zezuru (18%) from the Harare area, the Manyika (13%) from the Eastern Highlands, the Korekore (12%) from the Mt. Darwin area, the Rozvi (9%) from the Midlands, the Kalanga (5%) from the far west, and the Ndau (3%) from south of Mutare.

About 14% of the African population are Sindebele speakers, most of whom are Ndebele, from the southwestern area known as Matabeleland. The remaining 4% are Tonga, Birwa, Venda, Hlengwe, and others.

At the time of independence, the predominantly English-speaking whites numbered about 230,000. Since then, more than 150,000 have

© CAROL JOPP/ROBERT HARDING PICTURE LIBRARY LTD.

"The Smoke That Thunders," Mosi-oa-Tunya, or Victoria Falls, is Zimbabwe's best-known tourist attraction.

emigrated, reducing the white population to 80,000. The average age of the remaining whites is increasing. The Asian and Coloured (of mixed race) populations are minimal.

English is the official language, but Shona and Sindebele are widely used.

Religion. Traditional African belief systems predominate among Zimbabweans. The vast majority of the people practice animism, with a strong emphasis on ancestor worship. Some combine Christian and traditional beliefs. Nearly 25% of the people are Christians. A few are Muslims or Hindus.

ROBERT HARDING PICTURE LIBRARY LTD

Inyanga National Park lies in the Eastern Highlands near the border between Zimbabwe and Mozambique.

In the past, missionary activity provided rural people with their only opportunity to acquire secondary education. Many of the independence government leaders were educated at Catholic mission schools. The churches continue to speak out against government excesses, much as they did during white rule.

Urban-Rural Contrasts. Harare (formerly Salisbury) is the capital. In 1982 it had a population of 656,000, an increase of almost 70% over 1969. Chitungwiza, on the outskirts of Harare, is a sprawling settlement of 172,600. Bulawayo in Matabeleland, is the second-largest city, with a population of 413,800. Cities of 30,000 to 100,000 inhabitants are Gweru (formerly Gwelo), Kwekwe (Que Que), Kadoma (Gatooma), and Masvingo (Fort Victoria) on the plateau; Mutare (Umtali) in the Eastern Highlands; and Hwange (Wankie) in the Zambezi Valley. Between 60% and 70% of Zimbabweans remain in rural areas despite the prolonged drought of the early 1980's, which forced many rural people into urban centers.

The labor practices of the preindependence governments disrupted normal development of both urban and rural areas. Although the majority of the people are rural dwellers, they are overwhelmingly women, children, and old people. Many of the able-bodied men work in the cities as domestic labor or in menial factory jobs; others work in mines or on commercial farms, living at the site of employment. Those who have left dependents behind return to them infrequently but usually provide them with cash and food. Women remain in the rural areas and are responsible for growing food and tending to the young. Many Zimbabweans practice polygamy, and it is not unusual for a man to take a wife in the city and maintain another in his rural household.

Health. The government subsidizes a healthcare system for those earning less than Z\$150 a

month. In 1980 the country had one nursing person for every 1,190 people and one physician for every 6,580 people. Africans also rely on traditional healers (*n'angas*) for medical advice.

Public and private hospital facilities in the major cities are good. Church missions continue to serve the people in rural areas. Health facilities that were damaged or destroyed during the war have been rehabilitated, largely through foreign-aid programs. But many areas not served by public transportation have no clinic within a day's walk.

The infant mortality rate in 1981 was 72 per 1,000 live births, down from 118 in 1960. Life expectancy at birth is 55 years. The per capita daily calorie supply in 1980 was 1,793, 86% of the minimum requirement.

Poor diets, inadequate sanitary facilities, and lack of clean water sources create health problems for people in rural and poor urban areas. Diarrhea, malaria, measles, pneumonia, malnutrition, and trachoma are the most common diseases and causes of death. The incidence of typhoid is increasing. One half of rural children between the ages of eight and ten have bilharzia, an extremely debilitating infection contracted by swimming or bathing in slow-moving, snail-infested waters.

Education and Literacy. One of the government's primary objectives is to provide free primary-level education for all. Almost a sixth of the total annual budget has been spent on education, more than for any other purpose. In 1979 there were about 800,000 primary-school students; in 1983, more than 2 million. The government subsidizes private-school teachers' salaries. Enrollment in secondary schools increased from 73,000 to 300,000 between 1979 and 1983. Schooling is mandatory to the age of 16, and nearly 70% of the adult population is literate.

Social Change. Independence freed many young people from the strictures of the extended

family, but as traditional ways undergo change, societal mores are breaking down. For example, the incidence of young women abandoning newborn babies caused such concern among officials that the government endorsed publicly a family-planning program. About 14% of married women use contraceptives. Rural families tend to be large.

Unemployment among the young is a growing problem. The economy is not expanding fast enough to absorb the nearly 90,000 school leavers who enter the job market annually. In addition, thousands of former soldiers, skilled only in guerrilla tactics, must be incorporated into the economy.

The nation as a whole continues to suffer from rivalry between Mashona and Ndebele. As the army of the Mashona-dominated government tries to quell acts of terrorism in Matabeleland, many innocent Ndebele suffer and hostility between the two ethnic groups intensifies.

3. Government

The constitution of the Republic of Zimbabwe was drawn up at the Lancaster House Conference in London in 1979. It took effect on independence day, April 18, 1980. The constitution establishes a parliamentary system based on the Westminster model. The legislature is bicameral, consisting of a House of Assembly and a Senate.

The constitution stipulates that for ten years entrenched clauses such as those relating to the composition of Parliament and to dual citizenship may be amended only by unanimous vote of the House of Assembly. Dual citizenship means that a person who became a citizen at independence may retain prior citizenship in another country without being deprived of Zimbabwean nationality.

Parliament. The House of Assembly has 100 members, of whom 80 are elected by voters registered on a common roll. According to an entrenched clause of the constitution, the other 20 are chosen by voters on a separate white roll. Elections must be held at least once every five years, or within four months after Parliament is dissolved. House members are elected by their constituents under a system of universal adult suffrage.

The Senate, which has only delaying powers, consists of 40 members, 24 of whom are elected by the House. Another 10 are chiefs (5 Shona, 5 Ndebele) elected from their chiefdoms, and 6 are appointed by the president on the advice of the prime minister.

The Executive Branch and Civil Service. The president of the republic is elected for a maximum of two six-year terms by an electoral college composed of members of the House and Senate. His position is largely ceremonial. The Rev. Canaan Banana, an Ndebele, was elected as the country's first president.

The prime minister is head of his party, and he selects the members of his cabinet from either the House or the Senate. Most cabinet officials are former nationalist fighters or strategists. Few technocrats hold high office. In 1980 the Zimbabwe African National Union—Patriotic Front (ZANU-PF) won 57 of the 80 seats on the common roll. The party selected Robert Mugabe as prime minister.

The bureaucracy consists of permanent civil servants, with heads of departments subject to the general direction and control of a cabinet minister. The bureaucratic process is extremely slow. Many skilled, experienced whites have left government service, and their places have been filled by less experienced and less educated blacks. In addition, the bureaucratic ranks

In high-lying Harare many people wear sweaters on a cool day. Cafe umbrellas protect patrons from the sun's glare.

ERWIN & PEGGY BAUER

swelled after independence, absorbing nearly 35,000 job seekers within a few years.

The Judicial System. The legal system in Zimbabwe is based on an amalgamation of Roman and Dutch law that was brought originally to South Africa by Dutch trading companies and to Zimbabwe in the 1890's by settlers from South Africa. In 1973 trial by jury, which had been inherited from England, was abolished. In its stead are judges and assessors who determine guilt or innocence.

Six types of law courts exist. The Supreme Court, the final court of appeal, is headed by the chief justice, who is appointed for life by the prime minister. The High Court consists of two courts, an appellate division and a general division, presided over by the chief justice and other judges. Magistrates' courts are located in major urban areas and have civil and criminal jurisdiction over all cases except murder and treason. These courts are conducted by civil servants.

Of the primary courts, community courts are formal courts of record with trained presiding officers and limited criminal jurisdiction. They may interpret customary law. Village courts stem from the old chiefs' or headmen's courts. They may deal with civil cases involving less than Z\$500 and must restrict themselves to interpreting customary law.

Local Government. Three main administrative regions encompass the eight provinces. On the provincial level, governors are appointed by the prime minister and report to his office. Provincial administrators, who are civil servants, report to the ministry of local government.

Within the provinces, urban councils are made up of elected officials and administrative

staffs. They raise their own revenue by levying rates on municipal services. Rural councils represent commercial farmers and impose a unit tax on area residents. Urban and rural councils do not employ civil servants. District councils represent communal farmers and rely on administrative grants for their revenue. The district administrator is a civil servant.

The system of local administration established under white rule sorely neglected the small-scale African farmer. The government is endeavoring to compensate for past inequities by creating rural growth points with administrative and social facilities necessary for development.

Political Parties. Running parallel to the local government structure is the ZANU-PF party organization. From provincial chairman on down, party officials are actively involved in local affairs, often usurping the functions of government workers. The party is broadly based, encouraging people at all economic levels to join. It has an active youth wing and women's wing. Current government policy is to create a one-party state.

Within the party there are several contending factions, some based on ethnic heritage and others on ideological grounds. Political decisions often reflect the dominance or submission of one group or another.

Opposition parties include the Zimbabwe African People's Union (ZAPU), led by Joshua Nkomo; the United African National Council (UANC), led by Bishop Abel Muzorewa; and the Conservative Alliance (formerly the Republican Front and before that the Rhodesian Front), representing conservative elements of the white community and led by Ian Smith.

Workers load sacks of maize for transport to a bulk-storage site. Maize (white corn) is a dietary staple.

© PETER JORDAN/EPG

Continuation of the emergency-powers regulations left over from the Ian Smith regime of 1965–1979 gives the government extraordinary authority. It may detain people without trial and may bypass Parliament to enact legislation.

The government owns the major media outlets: television, radio, and leading urban newspapers. Political parties must apply to the government for permission to hold rallies.

4. The Economy

Zimbabwe is predominantly agriculture but has rich mineral resources and a highly developed infrastructure. Its wealth is controlled mainly by whites, both individual and corporate. Extractive and manufacturing industries generally are owned by foreign investors, usually British or South African.

The postindependence government of Prime Minister Robert Mugabe seeks to create a socialist state and thereby redistribute the wealth. However, it has moved cautiously in this direction, recognizing that it needs a strong economic base to work from.

Agriculture. White commercial farmers continue to own the prime farming land. Some blacks own freeholds, but most hold land in communal areas in the poorer, overcrowded regions. Most Africans are subsistence farmers. The government buys land from white farmers on a willing-seller, willing-buyer basis in order to resettle Africans. About 12,000 African families are resettled annually.

Tobacco and cotton are major export crops. With good rains, commercial and communal farmers grow enough maize (white corn) to feed the country, with a surplus for export. Winter wheat for domestic use is grown by commercial farmers on irrigated fields.

The size of cattle herds decreased substantially during the war and the drought. Efforts are under way to restore the herds, because beef will become an important export if the European Economic Community agrees to accept Zimbabwe beef. Tea, coffee, and sugar are also grown for export.

Forestry. Only three types of indigenous trees—mukwa, Zimbabwe teak, and Zimbabwe mahogany—are used in commercial operations. They are harvested from a 2-million-acre (800,000-hectare) woodland in Matabeleland for use in making furniture. Exotic trees like eucalyptus or *Saligna* gum are used for power-transmission poles and fence posts. Pine plantations feed the paper pulp industry.

Throughout the country deforestation is a major problem. Most of the people depend on wood for cooking, fuel, light, and heat. Because felled trees have not been replaced, soil erosion and river siltation have resulted.

Mining and Manufacturing. The mining industry suffered heavy losses and closures as a result of the world recession in the early 1980's. The government attempted to subsidize mines but found it too costly. Thousands of mine workers lost their jobs.

Gold is the most important of some 40 minerals mined in Zimbabwe. Most gold-mining operations are owned and operated as small workings. In 1983 the value of gold output reached a record \$194 million, more than the combined value of the next five most important minerals— asbestos, nickel, coal, copper, and chrome ore. The country has vast reserves of coal.

MONKMEYER PRESS

A mine worker carefully removes crystals of mica from surrounding rock. Zimbabwe produces over 40 minerals.

The well-developed manufacturing sector accounts for a fourth of the gross domestic product, the highest proportion in black Africa. Highly diversified, it supplies most of the country's needs for durable and nondurable goods and is an important earner of foreign exchange. Continued high performance depends on the availability of foreign exchange, replacement of managerial and technical skills lost through emigration, maintenance of the domestic consumer market, and replacement of obsolescent machinery.

Manufacturing is concentrated in and between the Harare and Bulawayo areas. During the period of steady growth between 1964 and 1974, intermediate and capital goods industries led the way as international trade sanctions encouraged import substitution. Production of metals and machinery nearly equals that of food processing in value. Two other major industries are textiles and clothing followed by chemicals, including fertilizers, pesticides, soap preparations, pharmaceuticals, and plastics.

The Hwange thermal power station is the largest consumer of coal. Electricity is generated from Hwange and from the Kariba Dam on the Zambezi.

Foreign Trade. Zimbabwe's major trading partners are South Africa followed by Britain, the United States, and West Germany. With the lifting of international trade sanctions that were imposed against the illegal government in 1965 to 1979, exports increased by more than 40% in four years. But in the same period imports rose by more than 65%.

Zimbabwe's major exports are cash crops—tobacco, cotton, sugar—and minerals—asbestos, nickel, gold, and ferroalloys. Its major imports are machinery, transportation equipment, spare parts, chemical products, and petroleum. The country runs a trade deficit of about \$500 million annually.

Transportation. The road network in Zimbabwe is extensive and well maintained. All

A farmhand loads tobacco onto a truck. Tobacco has long been one of Zimbabwe's leading commercial crops.

major roads and most secondary roads are paved. Tertiary roads are dirt but well graded.

Railroads link Zimbabwe with the Mozambican ports of Beira and Maputo and with South African ports. Other lines connect with Botswana and Zambia. The railroads are partially electrified.

The national airline is Air Zimbabwe. Most international flights use Harare International airport.

Tourism. Zimbabwe's tourist facilities were developed before the war, but the tourist trade did not revive afterward. The number of South African visitors declined, and European visitors remain uneasy about security. Several tourist hotels have closed.

The major attraction is Victoria Falls—or Mosi-Oa-Tunya, “the smoke that thunders”—on the upper Zambezi. Lake Kariba has fine facilities for tourists and anglers. Game reserves for viewing and hunting also draw visitors from Europe and the United States.

5. History

Late Stone Age Bushmanoids, who were hunters and gatherers, freely roamed the Zimbabwean plateau before about 1000 A.D. By then, Early Iron Age Bantu-speaking Negroids, migrating from the north, had absorbed the Bushmanoids or pushed them into the Kalahari desert.

The Bantu were agricultural and pastoral peoples who settled along the watercourses of the plateau. There they found a good climate, free of tsetse fly, and developed surface mining of gold, iron, and copper.

After 1000, Late Iron Age Bantu arrived and absorbed the earlier peoples. They brought with them improved mining techniques and an emphasis on cattle rather than goats and sheep. Eventually, they traded gold and ivory for ceramics, cloth, and beads brought by Muslims from the Indian Ocean coast.

Early States and Empires. By the 11th century the Karanga, a group of Late Iron Age Bantu, had

developed the southern plateau area and had formed the Zimbabwe state. Some grew wealthy from trade and mining, and they constructed elaborate walled settlements. Over time, craftsmen improved and refined stone-building techniques. Their efforts culminated in the construction of the Imbahuru (Great House) at Great Zimbabwe, near present-day Masvingo, during the 1300's and 1400's. Smaller structures in the same style of exfoliated granite were built in other areas where people spoke similar languages. At Great Zimbabwe, limited resources and overpopulation forced the occupants gradually to abandon their site by 1500. See also ZIMBABWE (ruins).

As people moved out of the Zimbabwe state, some went westward and established the Torwa state at Khami, near present Bulawayo. Others moved northward to the edge of the plateau. One such group traveled under a leader named Mutota to just above the Zambezi escarpment. The new state founded there was called Mutapa, and by the mid-1400's its influence had spread as far as the Indian Ocean coast in Mozambique.

After the Portuguese established themselves on the Mozambique coast in the early 1500's, they pushed into the interior along the Zambezi River, following the trade routes. The upheavals caused by the Portuguese wars with the local peoples forced groups to flee southward. Among them were the Rozvi. Because the Torwa state in the southern region was weak and splitting up, the Rozvi moved into that area. By the 1600's they had established themselves as masters of Torwa and called their new dynasty Changamire. They expelled the Portuguese from the plateau and ruled in the southwest until the Ndebele invaded the area and defeated them.

The Ndebele were Nguni peoples fleeing the havoc caused by Shaka's Zulus in the eastern region of present-day South Africa. In the 1840's, under Mzilikazi, the Ndebele destroyed the Changamire state; they raided Rozvi settlements for cattle and women, incorporated many of the people into their own state, and established their capital at Bulawayo (“the place of slaughter”).

The Ndebele are believed to have first used the word “Shona,” as a derogatory term for the people they had defeated. When the British arrived they extended the term to all the peoples native to the plateau.

Charter Company Territory. Other than scattered missionary groups, the first contingent of British arrived in 1890 carrying the flag of Cecil John Rhodes' British South Africa Company, (BSAC). They came in search of gold. Previously, a huge vein of gold-bearing rock had been discovered in the Witswatersrand of the Transvaal in South Africa. Believing that the vein extended northward and also remembering tales of the Queen of Sheba and the land of Ophir, the BSAC (chartered by the British crown in 1889) sent out the Pioneer Column of young men in search of gold. On Sept. 12, 1890, the Column raised the company flag on Harare Hill, where they proceeded to establish Fort Salisbury.

In 1888, Rhodes had sent his envoy Charles Rudd to make an agreement with Lobengula, the son of Mzilikazi and king of the Ndebele. In the Rudd Concession, Lobengula unwittingly gave the BSAC extensive mining rights. By 1893 the company realized that there was little gold in the norther plateau and moved south toward Matabele-

© ERWIN & PEGGY BAUER

Country women display their hand-crocheted work, a source of extra income for their families.

Ireland. A local disagreement between Shona and Ndebele served as an excuse for the BSAC to launch a full-scale attack against the Ndebele. The company destroyed Lobengula's kingdom and took over the prime lands.

With the defeat of the Ndebele, the Europeans began conscripting Africans to work the mines. In 1896 the Ndebele revolted against the conditions imposed on them. The Mashona in the northern areas also had been deprived of their lands, and as word of fighting spread they joined the Ndebele in battle against the Europeans. Although the uprising was soon put down by superior European firepower, this early resistance to outside rule is celebrated by Africans as the first "Chimurenga," or war of liberation.

The mines returned little gold. In order for the BSAC to recoup its expenses, it encouraged European farmers to settle and allocated the best lands to them. By 1901 there were 11,000 white settlers.

Although the British government was unwilling to assume any financial stake in the new territory of Southern Rhodesia, it did insist that the company give white settlers some legislative control. In 1907 settlers were assigned a majority of the seats in the legislature, and in 1914 they were allowed to assume the company's powers when its charter expired in 1923.

British Colony and Illegal State. In the 1922 referendum on the future status of the territory, the settlers voted to become a self-governing colony rather than be incorporated into South Africa. In 1923 a constitution was drawn up for the colony of Southern Rhodesia, giving Britain the right of veto on discriminatory and constitutional matters.

In 1930 the legislature passed the Land Apportionment Act, which divided the land between blacks and whites without regard to population numbers. Africans received the poorest and most inaccessible land. In addition, Africans were forbidden to compete with whites in growing cash crops such as tobacco. The 1934

Industrial Conciliation Act further restricted African competition in the work force. It ensured the availability of large numbers of Africans as cheap migrant labor.

The years between the two world wars were a time of enormous economic growth in the colony. Under Prime Minister Godfrey Huggins (1934 to 1953) the iron-and-steel industry was developed, the textile industry was established, and tobacco became a major export crop. Between 1938 and 1958, the economy grew at an annual rate averaging 9%. The colony attracted many white immigrants after World War II, especially from the United Kingdom. Between 1945 and 1958 the white population increased from 80,000 to 205,000.

In 1953, Huggins became prime minister of the newly formed Federation of Rhodesia and Nyasaland. The federation lasted until 1963, by which time measures had been taken to bring about majority rule in Nyasaland (Malawi) and Northern Rhodesia (Zambia).

Many factors had contributed to the growing spirit of nationalism on the African continent. Returning soldiers had fueled the impatience of the people to have full rights as citizens. Britain was unable to hold its colonies by force and unwilling to sustain the financial costs of them. And, at least in Southern Rhodesia, local conditions for blacks had worsened.

Anger over application of the 1951 Land Husbandry Act in 1955, by which semi-individual land ownership by Africans was shifted to communal ownership, led to the formation of the African National Congress (ANC) in 1957. The ANC was banned in 1959 but was replaced by the National Democratic party (NDP) in 1960.

As prime ministers of Southern Rhodesia, Godfrey Huggins and his successor Garfield Todd had inaugurated measures to end the segregationist policies adopted by the colony and to develop an educated black middle class. Todd proved too liberal for his own party and was replaced by Edgar Whitehead in 1958.

UPI-BETTMANN

Prime Minister Robert Mugabe was a leader of the Patriotic Front's struggle for the liberation of Zimbabwe.

Whitehead tried to maintain white support for his government while he defused nationalist stirrings. Believing that he had enough support from the black community to convince Britain that the colony should be granted independence, he invited the NDP to attend talks on a new constitution. The NDP rejected the terms of the proposed charter, which called for eventual, but far-off, majority rule. However, the white electorate endorsed the new constitution in a 1961 referendum.

Whitehead was unable to walk the line between black and white aspirations. In the 1962 elections, he frightened whites when he called for repeal of the Land Apportionment Act. Whites opposed to reform organized the Rhodesian Front (RF) and won the election overwhelmingly. Winston Field, the RF's first prime minister, was replaced in 1964 by Ian Smith.

Smith consolidated white political power, detained and imprisoned black opposition leaders, and discontinued negotiations with Britain on independence for the colony. On Nov. 11, 1965, he issued a unilateral declaration of independence (UDI), proclaiming the colony an independent nation.

Britain ruled out the use of force against the rebel government of "Rhodesia" and applied economic sanctions instead. The United Nations imposed mandatory sanctions that were adhered to by some members and circumvented altogether by others. Rhodesia freely traded with South Africa and with Portugal and its colonies. Sanctions had the unexpected side effect of strengthening import-substitution industries in Rhodesia.

The Nationalist Movement. During Smith's 14-year rule, many of the nationalist leaders were in detention or in exile. Moreover, dissension existed within and among the nationalistic groups. In 1963 the outlawed Zimbabwe African People's Union (ZAPU, successor of the NDP) split apart, mainly because of disagreement over decisions made by its leader, Joshua Nkomo. A new party was formed, the Zimbabwe African National Union (ZANU), led by the Rev. Ndabaningi Sithole. It too was soon banned, and in 1971 a

new internal party was formed, the African National Council, headed by Bishop Abel Muzorewa.

Guerrilla warfare began in the 1960's, but the nationalistic forces at that time were poorly trained and ill equipped. The 1966 "Battle of Sinoia (now Chinhoyi)" symbolically marks the beginning of the second "Chimurenga," although intensive fighting did not get under way until December 1972, in the northeast.

Events in Portugal had immediate effects on the future of Rhodesia. In 1975, a year after the military had taken control in Lisbon, the Portuguese government freed Angola and Mozambique from colonial status. The government that took power in Mozambique was sympathetic to the nationalist cause in adjacent Rhodesia, especially to ZANU freedom fighters.

With the end of Portuguese rule in Mozambique and an increase in military supplies to the guerrillas from the Soviet Union and China, South Africa and the United States put pressure on Ian Smith to come to terms with the nationalists. At the 1976 peace conference in Geneva, Smith accepted proposals that would lead to majority rule within two years. But agreement could not be reached on the form of an interim government, and the talks collapsed. In anticipation of the conference, Nkomo and Robert Mugabe, the new leader of ZANU, had formed the Patriotic Front (PF) to present a united nationalistic stand.

With the collapse of the talks, fighting intensified, bringing greater hardships to the African people, an increase in military spending, and attacks on refugee camps in Mozambique and Zambia by the Rhodesian military. As costs escalated, Smith attempted to forge an alliance with three internal national leaders: Muzorewa, whose party had been renamed the United African National Council (UANC); Sithole, head of a ZANU splinter group (ZANU-S); and Chief Jeremiah Chirau, leader of the Zimbabwe United People's Organization (ZUPO). They agreed on a new constitution and in April 1979 held elections based on universal adult suffrage. The Patriotic Front did not participate.

The UANC won the election, and Bishop Muzorewa became prime minister of the newly named Zimbabwe Rhodesia. However, his government was unable to end the fighting, even though its army was increasingly well supplied. Also, the new government was denied international recognition and the lifting of sanctions, because the internal settlement did not have the support of the majority of the Africans. The Patriotic Front was the only organization internationally recognized as representative of the African population.

The "front-line states"—Botswana, Mozambique, Zambia, and Tanzania—persuaded Britain to try to work out an agreement for an internationally acceptable independent Zimbabwe. In response Britain hosted a 14-week conference at Lancaster House, London, beginning in September 1979. Mugabe and Nkomo attended as the Patriotic Front, and a constitution acceptable to all parties was agreed on.

Until supervised elections could be held, Zimbabwe Rhodesia reverted to colonial status as Rhodesia. Elections held in February 1980 were contested by ZANU as ZANU-Patriotic Front (Mugabe), ZAPU (Nkomo) as Patriotic Front-ZAPU, the UANC (Muzorewa), and sever-

al smaller parties. ZANU-PF won 71% of the vote.

The Republic of Zimbabwe. In April 1980, on becoming prime minister of the Republic of Zimbabwe, Robert Mugabe faced a society divided by years of fighting. The government successfully integrated the forces of the three warring factions: the Rhodesian army and the guerrilla fighters of the ZANU and ZAPU armies. Today these groups form the national army.

Reconciliation between whites and blacks was achieved remarkably quickly. After an initial exodus of whites, nearly 200,000 remained. But economic conditions, declining quality of education, and various decisions taken by the government prompted many more whites to leave. As they departed, they deprived the country of sorely needed skills. Consequently, technological aspects of the infrastructure, such as the telephone system, deteriorated.

Mugabe introduced a rather vaguely defined ideology of "scientific socialism." Opposition within ZANU-PF continued over the pace and direction of change. Tensions between the predominantly Mashona ZANU-PF and the Ndebele-based ZAPU were exacerbated by terrorist activities in Matabeleland and army reprisals; by the detention of two ZAPU leaders even after the Supreme Court had acquitted them of charges; and by Mugabe's insistence on creating a one-party state, thus eliminating all opposition to ZANU-PF.

Aid from the international community cushioned economic problems in the early years of independence, giving the government sorely needed foreign exchange. International assistance also made possible government purchase of land in order to resettle people from overcrowded communal areas. The government's promises, though, far exceeded its ability to fulfill them as economic growth declined and inflation increased. Reduced foreign-currency allocations to importers hampered the manufacturing industry. And emergency economic measures introduced to slow the outflow of foreign currency further discouraged foreign investors.

Zimbabwe is a nonaligned nation. It re-

ceives aid from Eastern and Western nations, and the United States is its major donor. South Africa is its major trading partner; the two countries maintain trade missions in each other's capital although they do not have diplomatic relations. Zimbabwe has been instrumental in developing and strengthening the Southern African Development Coordinating Committee (SADCC), intended to bring about regional cooperation and eventual loosening of ties with South Africa.

ZIMBABWE, zim-bā'bwā, spectacular stone ruins in southern Zimbabwe, 17 miles (27 km) south-east of Masvingo. The name Zimbabwe is of uncertain etymology but possibly means "houses of stone." The Republic of Zimbabwe is named for the ruins, which are also known as Great Zimbabwe.

The size of the ruins and their relatively good preservation (partly restored) distinguish them from many others in the southern half of the country and adjacent territories. With few exceptions, the building stone of all these structures is a local granite that has weathered into flat-sided slabs.

Buildings. The Elliptical Building at Zimbabwe consists of a great oval circuit wall about 280 yards (256 meters) in circumference and 30

The massive stone ruins seen at Zimbabwe today were built of local granite over a long period beginning in the mid-15th century, but the site was inhabited as early as the 4th century.

TONY CARR—ALAN BARD ASSOCIATES

feet (9 meters) high (the top is dilapidated). The granite bricks are laid in fairly regular courses without through ties. Three fine entrances break the continuity and display the peculiar rounding of entrance ways and integrated steps unparalleled outside ruins in the republic, where curvature of plan is a general feature.

Within this great enclosure, notable features include a second wall, 100 yards (91 meters) long, parallel with and only 3 to 4 feet (0.9–1.2 meters) from the taller circuit wall, forming a long, forbidding passage. It widens into a semi-enclosed area, popularly called the Sacred Enclosure. Here stands the Conical Tower, a 30-foot (9-meter) tapering cone of solid masonry, with a basal diameter of 18 feet (5.5 meters). Excavations made underneath it in 1929 failed to reveal its purpose.

The Zimbabwe Acropolis is a wall-strengthened kopje (steep hill), some 300 feet (90 meters) above the Elliptical Building. Steep stone-stepped ascents lead up to and through crevices in the rock precipices, upon the crests of which are parapet walls of immense strength, edging level enclosures. As in the Elliptical Building, and elsewhere, these walled enclosures were originally filled with clay or *daga* floors and huts. Their frequent reconstruction caused constantly rising levels of debris, eventually up to 18 feet (5.5 meters) thick, making it necessary to raise the retaining walling.

Age and Origin. The age and origin of Zimbabwe have been debated since it was discovered in 1868. Historical assessment by archaeological methods has been cramped by the depredations of early English gold hunters, stimulated by widespread evidence of ancient gold mining, reported by Arab chroniclers in the 11th century A. D. The earlier view that the buildings were erected by Oriental prospectors, at periods variously placed from 2000 or 1000 B. C. down to the Christian era, was challenged by later scientific excavators, who unanimously affirmed that the structures were of native origin and of medieval and postmedieval age.

Between 1946 and 1962, carefully planned, unhurried archaeology was carried out on ruins in the country. This culminated in 1958 in excavations on the Acropolis and in the Elliptical Building at Zimbabwe. The results disclosed a far more integrated, though complex, history than anything possible before radiocarbon determinations replaced the former deductions based on datable imports. They indicated a prolonged occupation of the site beginning before the 4th century A. D. by people already using iron and living in pole-and-*daga* huts, but without stone walling. These people, contemporary but not identical with the earliest gold miners, were replaced in the 11th century by newcomers responsible for the earliest examples of granite walling. Not until about 1450 were the great stone monuments, as now known, begun in prolonged stages. Throughout this history the inhabitants are believed to have been indigenous, although tribally changing, Africans.

ZIMBALIST, zim'ba-list, Efrem (1889–1985), Russian-American violinist. He was born in Rostov-on-Don, Russia, on April 9, 1889. After studies with his father and with Leopold Auer at the St. Petersburg Conservatory, he made a sensationally successful appearance as a violinist at Berlin in 1907, and thereafter embarked on a brilliant European career as a virtuoso. On Oct. 27, 1911, he made his United States debut with the Boston Symphony Orchestra, playing the solo part in the first American performance of Aleksandr Glazunov's Violin Concerto. After a long series of international tours, including six visits to the Orient, he served as head of the violin department from 1928 to 1941 and as director from 1941 to 1968 of the Curtis Institute of Music, Philadelphia. The institute had been founded in 1924 by Mary Curtis Bok, whom he married in 1943. His first wife was the noted soprano Alma Gluck, who died in 1938. Zimbalist also was a composer and wrote the opera *Landara*. He died in Reno, Nev., on Feb. 22, 1985.

EFREM ZIMBALIST, JR. (1923–), the son of Efrem Zimbalist and Alma Gluck, was an actor, chiefly in films and on television. He starred in the TV series *The FBI* (1965–1973) and in the films *By Love Possessed* (1961), *The Chapman Report* (1962), and *Airport 1975* (1974).

ZIMMERMANN, tsim'or-män, Arthur, German statesman: b. Marggrabowa, East Prussia, Oct. 5, 1864; d. Berlin, June 6, 1940. He was counselor in the foreign office from 1908, undersecretary for foreign affairs from 1911 to 1916, and secretary of state for foreign affairs from November 1916 to August 1917. On Jan. 19, 1917, he sent a telegram to the German minister in Mexico, informing him that the German government had decided to open unlimited submarine war on February 1. The minister was told that he should propose to the Mexican president the conclusion of a German-Mexican alliance if, as the Germans expected, the United States gave up its neutrality as a consequence of the unrestricted submarine campaign. Mexico was to be urged to reconquer its "lost territory" in Texas, New Mexico, and Arizona, and to endeavor to win the cooperation of Japan against the United States.

Since the German government had complained that it could not freely communicate with its foreign missions concerning President Woodrow Wilson's proposal of December 1916 to mediate among the warring powers, the United States Department of State had agreed to send such German messages over its own lines. The coded Zimmermann dispatch consequently was cabled by the American embassy in Berlin to the Department of State in Washington and delivered to the German ambassador, who transmitted it to Mexico City. The British intercepted and deciphered it, however, and presented the full text of what became known as the "Zimmermann note" to the United States government after Germany's announcement of unlimited submarine warfare. The note was published in the United States on March 1, 1917. It aroused strong anti-German feeling there and was an important factor in prompting the American declaration of war on Germany on April 6.

Hajo HOLBORN, Author of
"A History of Modern Germany"

ZINC, a shiny white metallic chemical element with a bluish gray luster. In the metal trades zinc often is known as spelter, especially when in the form of ingots, plates, or slabs. It is one of the four most important metals from the standpoint of quantity produced, being exceeded only by steel, aluminum, and copper, in that order. Zinc is widely used as a protective coating on steel products, as the major ingredient in die-casting alloys, and as an ingredient (together with copper) of brass. It is also an important ingredient in the manufacture of rubber and paints.

History. Accurate knowledge of zinc has been acquired only in the last 200 years. This is because zinc is one of the more active elements chemically, and as a result its ores as found in nature are rather difficult to convert to the metal.

Zinc was in use as a constituent of brass by the Romans and certain civilizations of the Middle and Far East more than 2,000 years ago, but the fact that it was a distinct metal was not recognized until much later. Philippus Aureolus Paracelsus invented the name "zinck" for a substance produced in lead-silver smelting furnaces, but he regarded it as a "bastard of copper." In 1721 the German Johann Friedrich Henckel isolated zinc, and that date must be considered as marking the discovery of zinc by the Western world. It is true, however, that elementary zinc was being made in China and perhaps in India more than 300 years earlier, some of it apparently finding its way to Europe as early as the 17th century. Undoubtedly some knowledge of the Oriental procedure had reached England, and in 1740, William Champion began smelting zinc at Bristol. It was not until 1807, however, that the first successful operation was set up on the continent of Europe, at Liège, Belgium.

Zinc was first produced in the United States in 1835 at the Washington, D. C., arsenal from New Jersey ores. Between 1850 and 1860 various experiments aimed at smelting zinc were made, but it was not until 1860 that commercial success was attained at La Salle, Ill., and South Bethlehem, Pa.

Properties. The chemical symbol for zinc is Zn. Zinc belongs to group II of the periodic table of elements. Its atomic number is 30, and its atomic weight is 46.37. The metal has a density of 7.133 and a hardness low to intermediate among metals. It melts at 419.5°C (787°F) and boils at $906^{\circ}\text{C} \pm 1^{\circ}\text{C}$ (1663°F). Zinc is very ductile in the temperature range of 100° to 150°C (212° – 302°F), but at 200°C (392°F) it is brittle. Metal of high purity is ductile even at room temperature, but ductility decreases with increased content of impurities.

Zinc's outstanding chemical property is its decidedly active or electropositive character, only aluminum and magnesium, of the more common metals, exceeding it in this respect. This characteristic is the basis for the use of zinc in galvanizing or coating steel products, which over the years has ranked as zinc's most important application. The coating of zinc is corroded preferentially or sacrificially, in this way protecting the steel.

Pure zinc is highly resistant to attack by dry air except at elevated temperatures, but moist air will attack the metal superficially at room temperature, the end product under normal conditions being a hydrated basic carbonate. The properties of the zinc, both chemical and physi-

cal, vary with the grade or purity of the metal. Zinc is soluble in alkalis and acids but insoluble in water. Most of its compounds are white, and they are fairly soluble in water.

Production. World production of smelter zinc has shown a fairly steady increase during the last few decades, reaching a total of nearly 6 million metric tons by 1980. U. S. production peaked in the late 1960's and then began to decline. Until 1971 the United States was the world's leading producer of smelter zinc. In that year Japan became the leading producer, and by 1980, U. S. production was exceeded by that of Japan, the USSR, and Canada. Other major producers, in declining order of importance, are West Germany, Belgium, Australia, France, Poland, and Mexico.

Zinc ores are fairly widely distributed throughout the world. In the United States, Idaho, Montana, Oklahoma, Arizona, and Utah have all been major producers at one time, but the leading zinc-producing states in the late 1970's were Missouri, Tennessee, New York, and Colorado.

The zinc consumed by nations is roughly correlated with the extent of their industrial development. For example, the highly industrialized United States uses about one fifth of the world's total output of zinc.

Technology. The chief ore of zinc is the sulfide (ZnS) known as sphalerite or zinc blende (see SPHALERITE). Oxidized ores of zinc, such as smithsonite (ZnCO_3), zincite (ZnO), willemite (Zn_2SiO_4), the hydrated silicate hemimorphite ($\text{Zn}_4\text{Si}_2\text{O}_{10}(\text{OH})_2 \cdot \text{H}_2\text{O}$), and franklinite (an oxidized zinc, manganese, and iron mineral), are also common in various parts of the world, but they have relatively little commercial significance as compared with the sulfide, and almost invariably the percentage of recovery of these ores is smaller. See FRANKLINITE; SMITHSONITE; WILLEMITE; ZINCITE.

The zinc content of ores mined has decreased steadily over the years, but improved mining and ore treatment methods have tended to compensate economically for this drop in zinc content. The fact that one or more other metals such as lead, copper, gold, silver, cadmium, and even germanium are almost always associated with zinc has permitted the exploitation of lower grade ores, although separation of these various metals has posed problems.

Since, under present-day circumstances, most zinc ores are too low grade for direct smelting, they are first crushed to free the valuable mineral particles, which are then concentrated by gravity and flotation methods. About 90% of the sulfide zinc is recovered; recovery of the much less frequent oxidized zinc content runs all the way from a few percent to 85%.

The next major step in the production of zinc metal is conversion by roasting the zinc sulfide content of the concentrates to zinc oxide. This is necessary whether electrolytic or pyrometallurgical procedures are subsequently used. A by-product of the roasting operation is sulfur dioxide-containing gas, which at many plants is converted to sulfuric acid.

In the electrolytic process, the roasted zinc concentrate (calcine) is leached with a dilute sulfuric acid solution to convert the zinc to a sulfate. The solution is then purified to remove contaminating elements such as copper, cadmium, cobalt, and germanium, and electrolyzed in suit-

ably constructed cells. The zinc, which has a high degree of purity, is deposited on aluminum cathodes, which are periodically removed from the electrolyte and stripped. These zinc sheets are melted in a furnace and cast into ingots or pigs called slab zinc in the United States, and elsewhere usually termed spelter. The process is cyclic: the electrolysis of the zinc-bearing solution regenerates sulfuric acid, and this spent electrolyte is used for further leaching of zinc calcine.

Pyrometallurgical procedure calls for the distillation of zinc from the roasted concentrate by one of three general methods. These, in the order of their development, employ: (1) batch horizontal retorts; (2) continuous vertical retorts fired by fuel; and (3) continuous vertical retorts heated electrothermally. Whatever the method, coal or coke is used to reduce the zinc oxide to zinc vapor. The zinc-containing vapor and the hot reducing carbon monoxide gas pass into condensers of various types, and the condensed metal is then cast into slabs.

Sizable operations have also been developed for the recovery of zinc from zinc-base scrap. These are carried out mainly at what are called secondary smelters, although some scrap is still treated at primary smelters.

Grades and Prices.—Slab zinc is available in six standard grades, varying from about 98.3 percent zinc (Prime Western, produced chiefly by the horizontal retort process) to 99.99 percent (Special High Grade, produced primarily by the electrolytic zinc process, although vertical retorts with a controlled fractionation column can also provide this grade). Between these grades, in order of increasing impurity content, are High Grade, Intermediate, Brass Special, and Select. The chief impurities are lead, cadmium, and iron. Special High Grade accounts for about 40 percent of total United States production, and Prime Western for about an equal proportion. The price of zinc varies from about 10 cents to 15 cents per pound, depending upon the grade and conditions of the metal market.

Uses.—As indicated previously, the major use of zinc is as a protective coating for steel, to which it is applied by some method such as hot dipping (galvanizing), electroplating, or spraying (using molten zinc). The first has become the most important method since World War II because of the rapid installation of high speed continuous galvanizing lines for steel strip. Zinc is more active in a galvanic couple than the coated iron and steel, and consequently is attacked while the coated metal is protected. See also GALVANIZING.

Another application, similar in principle, utilizing the electropositive character of zinc, is the provision of galvanic protection for underground and underwater installations of iron and steel such as storage tanks, pipelines, piers, and ships' hulls. Cast anodes of zinc are bonded to the structure to be protected. A slight galvanic countercurrent is generated due to the greater electrochemical activity of the zinc, thus protecting the iron or steel at the expense of the zinc which undergoes a controlled long term corrosion. This is called cathodic protection.

The use of zinc and zinc-base alloys for making low cost, high quality, high finish die castings has increased rapidly and now consumes approximately as much zinc as is used for galvanizing. Zinc die castings are used extensively in automobile and building hardware, electrical appliances,

tools, business machines, and toys.

Another, though decreasingly, important use of zinc is in alloying with copper to form brass, which contains from 3 to 45 percent zinc, usually about 30 percent. Still another use is the manufacture of rolled zinc to make sheet, strip, ribbon, foil, plate, rod, and wire. Typical applications are dry-cell batteries, extruded cases for radio condensers and tube shields, weather stripping, roof flashing, photoengraving plates, and anodes for cathodic protection referred to previously.

Secondary zinc finds various applications according to its analysis, the chief outlets being conversion to slab zinc, zinc dust, or brass and bronze alloys. Zinc dust, because of its physical condition, is quite reactive, and its applications depend primarily on this fact. It varies from about 95 percent to more than 99 percent metallic zinc, with zinc oxide as the chief impurity, and is sold under close specifications as to metallic content, evenness of grading, and fineness of particles. Chief outlets are in the chemical, textile, dye, paper, and metallurgical industries. It is used also in corrosion-resistant paints and coatings. When high purity is required in the zinc dust, refined zinc may be the source of the product.

Compounds.—The most important commercial compound of zinc is the oxide (ZnO). The method of production is closely akin to the retort process used for the metal, since the zinc must first be produced in vapor form, whether it is to be condensed to metal or oxidized. If the zinc vapor is oxidized directly without being condensed, the product is known as American- or direct-process zinc oxide. If the zinc vapor is first condensed to metal before final vaporization and oxidation, it is known as French- or indirect-process oxide. The grades produced by each process are numerous and are controlled to give the properties desired for specific applications.

Zinc oxide is a white compound with a high refractive index, and that fact, together with its high toxicity for mildews and fungi, accounts for its wide use as a paint pigment. Still more important from the standpoint of the quantity required is the use of zinc oxide in rubber, both natural and synthetic. It aids in the curing process, increases the mechanical strength, reduces heat generation, and facilitates heat dissipation. The usual addition is about 3 to 5 percent. Other important uses of zinc oxide are in ceramics, coated fabrics and textiles, floor covering, cosmetics, and pharmaceuticals. Another article of commerce, but of much less importance, is leaded zinc oxide (5 percent or more of lead), used almost entirely in the paint-making industries.

Other than the oxide, the two most important commercial compounds of zinc are the sulfate (ZnSO_4) and the chloride (ZnCl_2). The chief uses of zinc sulfate are in the manufacture of rayon and for agricultural purposes—for example, in the citrus industry as a trace fertilizer and in sprays for controlling certain plant diseases. It is used also in the manufacture of chemicals, flotation reagents, and glues, and in the medicinal, rubber, and mineral industries. Zinc chloride is used for preserving and fireproofing wood, in soldering and tinning fluxes, for various purposes in the processing of textiles, and in battery making and galvanizing. Other zinc compounds of lesser commercial importance are the acetate, borate, carbonate, chromate, silicate, and sulfide,

and certain organic compounds used in driers and metallic soaps such as the palmitate, stearate, oleate, and naphthenate.

The pigment lithopone should be mentioned also, although its importance has declined markedly since 1929. It is a coprecipitated pigment of zinc sulfide and barium sulfate made by reacting solutions of zinc sulfate and barium sulfide. It finds use in such industries as paint, floor covering, coated fabrics and textiles, and rubber.

Biological and Significance and Toxicity. It is now established that zinc has physiological importance as a trace element in animal nutrition, appearing to be essential to growth. The total amount of zinc in the human body is estimated to be about 2 grams, or $\frac{1}{14}$ ounce.

Ordinarily, zinc is not regarded as toxic, although the ingestion of excessive amounts with food or drink will cause disordered digestion. In general, the human skin has a high degree of tolerance for zinc and zinc salts. However, the inhalation of zinc oxide fumes, wherever they may be encountered in industrial operations, may result in distinct physiological disturbances of one or two days' duration. The effect is not cumulative, and elimination of the conditions which induced the malaise is more important than the treatment.

ZINCITE, zin'gīt, a mineral, ZnO , dark red to orange when massive, but yellow when powdered. It has a hardness of 4–4.5 and a specific gravity of 5.4–5.7. A minor ore of zinc, it is associated with other zinc minerals in crystalline limestones in Sussex County, N.J., but is unimportant commercially in other districts. It crystallizes in the hexagonal system without a principal plane of symmetry. The name "zincite structure" is applied to all substances that have a similar internal geometrical arrangement of atoms; in other words, those that belong to the same space group as ZnO . Silicon carbide is an example.

ZINDER, zin'dər, a city in south central Niger, West Africa, about 450 miles (720 km) east of Niamey. It is situated in an area strewn with large granite boulders, and part of the city is built of red mud. Zinder is a trading and agricultural center, chiefly for millet, wheat, manioc, peanuts, beans, cattle, and sheep.

Described by the German explorer Heinrich Barth in 1853 as the "Gate of the Sudan," it was the capital of the old Emirate of Damagarim, controlled by the Kingdom of Bornu. It connected Bornu with the North African coast along the western route. The historic Kelowi salt caravan passed through Zinder. The town was occupied by the French in 1899 and was the capital of the former French colony of Niger from 1922 to 1926. Population: (1977) 58,436.

JOHN RALPH WILLIS, JR.

Editor, "The Northern Tribes of Nigeria"

The common garden zinnia (*Zinnia elegans*).

ZINNIA, zin'ē-ə, a genus of annual or perennial (subshrubby) plants of the Compositae family consisting of about 17 species, native to North and South America, mainly Mexico. The genus is named for Johann Gottfried Zinn (1727–1759), who was professor of medicine at Göttingen, Germany. Two species are most frequently grown as annuals.

Zinnia elegans, of Mexican origin, the species from which the most common garden zinnias have been developed, bears the common name "youth-and-old-age." It has stiff hairy stems and opposite leaves which are broad near the base and clasp the stem, tapering, with smooth edges, to a pointed apex. Flower heads are borne at the end of branches. They follow the pattern of having fertile male florets and fertile bisexual disc florets, but the disc is often lacking in cultivated double types. In the latter the florets occur in several overlapping, superimposed series.

The color range of available varieties of *Z. elegans* extends from white through light and deep yellow to orange, salmon, scarlet, crimson, rose, magenta, lilac, violet, and purple, and includes some bicolors. Size in this species varies according to type from 3-foot (1-meter) plants bearing 5- or 6-inch (127–152 mm) flowers to plants less than a foot (0.3 meter) high with flowers 2 inches (51 mm) or less in diameter. Particularly in the larger types, there is considerable variation in floret shape, in which curled and quilled forms have been developed.

Z. angustifolia is a bushy plant about a foot high, with plentiful yellow or orange heads 1–1½ inches (25–38 mm) across and available in a double variety. Florets may sometimes be marked with maroon. Zinnias are easy to grow in a sunny location and deserve their great popularity as garden flowers.

ZINOVIEV, zo-nôv'yaf, Grigori Yevseyevich (1883-1936), Russian Communist leader. He was born in Yelizavetgrad (Korovograd), Ukraine, on Sept. 11, 1883. After working with Lenin in organizing the Bolshevik wing of the Russian Social Democratic party in 1903, he was forced to flee from Russia in 1908.

Zinoviev spent the early years of World War I abroad with Lenin, who returned to Russia with him in 1917 when the czarist regime began to totter. Zinoviev was president of the Petrograd Soviet and became a member of the Politburo in 1918. The next year he was chosen president of the Communist International. An alleged letter by him, calling for revolution in Britain, was an issue in the 1924 election campaign when the first British Labour government was defeated.

When Lenin died, Zinoviev, Lev Borisovich Kamenev, and Joseph Stalin ruled for a short time as a triumvirate, but presently the first two joined with Leon Trotsky against Stalin. Their opposition failed, and Zinoviev was expelled from his offices and from the Communist party (1926-1927). He was readmitted to the party after recanting his views, but in 1935, after being accused by Stalin of complicity in the murder of Sergei Mironovich Kirov, he was convicted of treason and conspiracy and was sentenced to 10 years in prison. In 1936 he was tried again with many other leaders on charges of plotting with foreign powers against Stalin. He confessed to various fabricated treasonable acts and was executed in Moscow on Aug. 25, 1936. In 1988 the Soviet Supreme Court annulled the sentences of Zinoviev, Kamenev, and other Bolshevik leaders who had been condemned in Stalin's show trials.

ZINZENDORF, tsin'tsên-dôrf, Nikolaus Ludwig, Count von (1700-1760), German religious leader. He was born in Dresden, Saxony, on May 26, 1700. His parents were devoted to Pietism, and Philipp Jakob Spener, founder of that movement, was his godfather. He was educated at the University of Wittenberg. By birth and training he was fitted to serve as a courtier, but his deep religious vocation made him unhappy in a minor post at the court of the king of Saxony in Dresden. He came to his life work almost accidentally when in 1722 he permitted some members of the Moravian sect, fleeing from persecution in Austria, to settle on his estate near Dresden. Their small village, which was given the name Herrnhut (the Lord's Watch), occupied more and more of his time, and in 1727 he resigned his court place and devoted himself to this community as a spiritual father.

Zinzendorf's most characteristic theological emphases were upon a personal conversion to Christ and a constant close personal fellowship with him. These principles can be seen in his plans for the "brotherhood" at Herrnhut. Zinzendorf insisted that its members take the sacrament from the Lutheran parish priest, but the spirit of the group had little in common with Lutheranism. The whole community was divided into "choirs" determined by the age, sex, and marital status of the members, and it has been described as a monastic system based upon the family.

In 1734, Zinzendorf was ordained a Lutheran minister, possibly believing that this would silence some of the criticism that was being directed against him. Nevertheless, in 1736 he was exiled from Saxony because the authorities

feared that he was creating a sectarian denomination on his estate. In 1737 he was ordained a bishop of the Moravian Church. The Saxon authorities did not repeal his banishment until 1747, and Zinzendorf spent the rest of his life moving among the various Moravian settlements and mission stations. He spent the year 1742 in Pennsylvania, where he was responsible for naming and establishing the Moravian community of Bethlehem. In 1749-1755 he lived in England. He died in Herrnhut, Saxony, on May 9, 1760.

On his return from America, Zinzendorf began to stress the need for a childlike response to Christ. Sentimentality, the greatest danger in Pietism, turned this teaching into an unfortunate episode known as "the sifting period," which was marked by some extravagant tendencies. This episode, though short lived, was not forgotten by Zinzendorf's opponents.

Zinzendorf wrote hundreds of hymns, many of which are still used widely outside the Moravian Church. His main achievement was to revive the scattered and virtually extinguished Moravian Church, to mold it into a brotherhood based on an evangelical pietistic theology, and to give it a worldwide vision for missionary service.

ZION, zî'an, or **SION**, sî'an, a synonym for Jerusalem. Originally it was the name of a Jebusite fortress on the southeastern hill (called Ophel) of the present city. After David captured it (about 1000 B.C.), it became known also as "the city of David."

When David moved the ark of Yahweh to Araunah's threshing floor, on a site north of the original stronghold, and especially after Solomon built the Temple there, the name Zion was gradually transferred to this area and received a sacred meaning (II Samuel 6:10-12; I Kings 8:1 ff.; II Chronicles 3:1 ff.). By extension, it came to be applied to the cultic "dwelling" of Yahweh on earth (Isaiah 8:18; and about 200 other references in the Old Testament, the Apocrypha, the Pseudepigrapha, and the New Testament). The term was used also for the congregation of the post-Exilic Jews (Psalms 126:1; 129:5; Isaiah 33:14); the true Israel (Romans 9:33; 11:26; Hebrews 12:22; I Peter 2:6); and the age to come (Revelation 14:1).

During the Christian era, the population of Jerusalem moved to the western hill, which is known as Sion to this day. It contains the so-called Tower of David (a Herodian structure); and the traditional sites of Joseph Caiaphas' palace, the Cenaculum (place of the Last Supper), the Dormition of the Virgin (place of Mary's death), Nebi Daoud (Frankish and Muslim tomb of David), and St. Peter in Gallicanté ("at the cock's crow").

ZION NATIONAL PARK, zī'ən, a national park in southwestern Utah, mostly in Washington county. Covering 147,035 acres (59,550 hectares), the park is a region of deep, narrow canyons with vertical walls, massive rocky domes, and pinnacles of gorgeous colors, mostly varying tones of red. The park is open all year.

Notable features of the park include Sentinel Mountain (7,157 feet, or 2,182 meters), the Watchman, East Temple, the Great White Throne (6,744 feet, or 2,055 meters), Angels Landing, and Cathedral Mountain.

Zion Canyon, which is nearly half a mile (0.8 km) deep and 8 miles (13 km) long, was cut by the North Fork of the Virgin River, which falls 50 to 70 feet (15–21 meters) in a mile (1.6 km). The park may be entered by the Zion Canyon Road (state highway 15) from the south, above Springdale, the park headquarters. At the Zion Canyon Junction, one may continue north or turn east on the Zion-Mt. Carmel Highway, which climbs by a series of six switchbacks to the mile-long Zion-Mt. Carmel Tunnel. A number of open galleries in the tunnel walls provide sweeping views of the canyon.

Much of the park consists of undeveloped country. Vegetation varies according to terrain and altitude, from cactus and yucca through broad-leaved trees such as cottonwood, ash, and maple, to pinon pine and juniper, with pine and fir at higher elevations. Wildflowers include datura, columbine, shooting star, monkey flower, and the white evening primrose. Rocky Mountain mule deer and mountain lions are fairly common, and smaller animals are abundant. The birdlife includes many species.

Zion Canyon was discovered in 1858, and the region was settled about 1861 by Mormons from the Great Salt Lake Valley, who gave it the name of Zion, "the heavenly city of God." It was set aside as Mukuntuweap National Monument in 1909 and was established by Congress under its present name in 1919. The area of Zion National Monument (Kolob Canyon), created in 1937, was added to the park in 1956.

ZIONISM, zī'ən-izm, the age-old Jewish aspiration and the modern movement to return to the Land of Israel. The term was coined in 1893 by Nathan Birnbaum, an Austrian author.

The longing of the Jews for their ancient homeland resulted in 538 B.C. in the return of Babylonian exiles and the establishment of the second Jewish Commonwealth, which survived for more than six centuries until it was destroyed by the Romans in 70 A.D. Thereafter, for 18 centuries, the Jews nevertheless always had a community in Palestine. Most Jews, however, lived in the Diaspora, where daily and on holidays they prayed for redemption, the ingathering of the exiles, and the restoration of David's throne in Zion—that is, Jerusalem. Through the ages a trickle of Jews settled in the Holy Land.

The First Aliya (Hebrew for "going up," or immigration) from Russia and Rumania, consisting of members of the Hoveve Zion (Lovers of Zion) movement, began in 1882. They established a number of agricultural settlements in Palestine, which, from 1890, had the support of the French Jewish financier Baron Edmond de Rothschild.

Theodor Herzl, a Jewish correspondent for an Austrian newspaper, witnessed the anti-Semitic manifestations that accompanied the trial in Paris

UNION PACIFIC RAILROAD PHOTO

Utah's Zion National Park is a spectacular region of many-colored canyons and towering sandstone cliffs.

of Alfred Dreyfus, a Jewish captain in the French army who was accused of treason. In his book *The Jewish State* (1896) Herzl advocated the establishment of a Jewish state as the only solution to the Jewish question. Within a year he created the World Zionist Organization, and in August 1897 he convoked the First Zionist Congress in Basel, Switzerland, which signaled the birth of political Zionism. Herzl devoted the remaining years of his life to securing a charter from Turkey for an independent Jewish Palestine and to organizing Zionist institutions, such as the Jewish Colonial Trust (1898) and the Jewish National Fund (1901).

Zionist activity in the Diaspora brought a renewed wave of immigration to Palestine with the Second Aliya of 1904–1914. The number of rural settlements increased; the first kibbutz (communal village), Degania, and the city of Tel Aviv were founded in 1909; and the Technion (later Israel Institute of Technology) was established in Haifa in 1912.

Zionist leaders, headed by Chaim Weizmann (later the first president of Israel), spurred the British government in 1917 to issue the Balfour Declaration in which Britain undertook to facilitate the establishment of a Jewish national homeland in Palestine. The declaration was endorsed by France, Italy, and other European powers, and Zionists in the United States secured the support of President Woodrow Wilson.

After World War I the Allied powers approved the declaration, and the League of Nations awarded a mandate for Palestine to Britain in 1922. Sir (later Viscount) Herbert Samuel served as the first high commissioner for Palestine (1920–1925). The Third and Fourth Aliya (1919–1928) brought middle-class elements into the country and signaled the beginnings of its industrial development. The Zionist congresses became virtually a parliament for the movement, with meetings every two years in a central or west European city. Numerous parties—notably General Zionists, Mizrahi, Poale Zion, and Revisionists—were represented.

In 1929, under the leadership of Weizmann, the World Zionist Organization was expanded into the Jewish Agency for Palestine in which Zionists and non-Zionists could cooperate in the rebuilding of a Jewish national home. Jewish

immigration to Palestine from Germany and central Europe increased with Hitler's rise to power. The Fifth Aliya (1929–1936) brought 188,000 legal and 12,000 illegal Jewish immigrants to Palestine, and by 1936 the number of Jewish residents had increased to 400,000, or 30.6% of the total population of the country. Arab resentment at the growing Jewish presence resulted in riots in 1929 and 1936.

In 1939, on the eve of World War II, the British government, trying to win Arab support, issued a White Paper calling for a halt to Jewish immigration and severe restrictions on land purchases by Jews. During the war the center of the Zionist movement shifted from Europe to the United States, and one of its central tasks was the rescue of endangered Jews on the continent. The effort was largely futile. The United States and its allies gave chief priority to defeating Germany, and no country was willing to admit large numbers of refugees. The number of Jews allowed by the British to enter Palestine was insignificant in relation to the need. Faced with the enormity of the Holocaust, American Zionist organizations endorsed the Biltmore Program (May 1942), demanding the establishment of an independent Jewish state ("commonwealth") in Palestine.

After the war, the Zionist leaders recognized that only a Jewish state in a partitioned Palestine could win the approval of the United Nations. Finally, on Nov. 29, 1947, the UN General Assembly passed a resolution to partition Palestine into separate Jewish and Arab states. Britain announced that it would withdraw its forces. On May 14, 1948, the State of Israel was proclaimed in Tel Aviv by David Ben Gurion, with immediate recognition by the United States and the Soviet Union. On the very day of its birth Israel was attacked by the neighboring Arab states. An unbroken front of Arab hostility was maintained for more than 30 years until Egyptian president Anwar el-Sadat made his historic visit to Jerusalem that resulted in the Israeli-Egyptian peace treaty of 1981.

Throughout its existence Israel relied on the Zionist movement for aid in bolstering its economy and defense forces, in securing immigrants to increase its manpower and agricultural and industrial output, in furthering its technological development, in maintaining its high standards in science and medicine, and in countering growing Arab influence in the United Nations and other international bodies. By the 1980's, practically all Jews of the Diaspora had become committed to Zionism at least in the sense of supporting Israel.

ZIONIST ORGANIZATION OF AMERICA (ZOA), a constituent of the World Zionist Organization, with national headquarters in New York City. It was organized in 1897 as the Federation of American Zionists and adopted its present name in 1915. The World Zionist Organization was originally formed to work for the establishment of a homeland in Palestine for the Jewish people, an aim that was attained with the creation of the State of Israel in 1948. The Zionist Organization of America now seeks to safeguard the independence of Israel as a free and democratic commonwealth, to assist in its economic development, and to promote Jewish cultural creativity.

ZIRCON, zûr'kôn, in mineralogy, the native zirconium silicate, ZrSiO_4 . Its crystals are tetragonal and isomorphous with thorite, zirconite, cassiterite, and rutile. Though its crystal forms are extremely varied, they are usually prisms terminated by pyramids. Small crystals frequently show a wealth of faces, among which the "zirconoid," or ditetragonal pyramids, are prominent. Zircon is a heavy mineral, its specific gravity varying from 4 to 4.8, and it has a characteristic adamantine luster. Though it is often nearly or quite opaque, transparent crystals are not uncommon. Owing to its hardness (7–7.5), strong double refraction, and the variety of rich colors in which it is found, it has long been prized as a gem. Its dispersive power is excelled only by the diamond. Hyacinth or jacinth includes reddish, orange, or brownish gem stones, which can be turned colorless by extreme heat, and then are marketed as "Matura diamonds." Jargon or jargon is the name of the colorless, yellowish, grayish, or smoky varieties.

The finest zircon gems come from Ceylon and New South Wales, Australia, while excellent translucent to opaque crystals occur in Arendal, Norway; the Ural Mountains, USSR; Ontario and Quebec, Canada; Essex and Orange counties, N.Y.; the Pikes Peak district, Colo.; and Henderson County, N.C. The mineral is also found in Florida and California. Quantitatively, Brazil and India are important sources.

ZIRCONIUM, zûr-kô'nē-əm (symbol Zr), a metallic chemical element with atomic number 40. Zirconium was discovered by Martin Heinrich Klaproth in 1789 while he was studying some semiprecious stones from Ceylon. It is in Group IVb in the periodic classification of the elements, along with hafnium and titanium. It has an atomic weight of 91.22, being made up of five stable isotopes of atomic mass numbers 90, 91, 92, 94, and 96, and three that are unstable, namely, 93, 95, and 97.

The known deposits of zirconium are greater than the sum of all copper, nickel, lead, tin, zinc, and mercury deposits and constitute 0.028 percent of the earth's crust. In the United States deposits occur in Florida, California, Oregon, and Idaho, and large reserves are found in Australia, Brazil, and India.

Zircon, ZrSiO_4 (zirconium silicate), and baddeleyite (almost pure zirconium dioxide) are the commercial source minerals of the metal and its compounds. Zircon and baddeleyite may be decomposed into more chemically active compounds either by fusion with NaHSO_4 (sodium bisulfate) or $\text{Na}_2\text{S}_2\text{O}_7$ (sodium pyrosulfate) or by the action of strong reducing agents, such as carbon, in an arc furnace.

Uses. Because zirconium has a very low tendency to absorb slow neutrons and a remarkable resistance to corrosion over the wide range of conditions that can occur in reactor service, it is extremely useful in the field of nuclear energy. Other uses include surgical instruments, pins, screws for bone repairs, spinnerets for the spinning of rayon fibers, alloys, and powder metallurgy. The metal in powdered form is used as an ammunition primer, in smokeless flash powders, in blasting caps, and as a "getter" in vacuum-tube manufacture.

Compounds and Their Uses. Zircon, the chief ore of zirconium, is extremely inert chemically and is stable up to about 1500° C, above which it dissociates into zirconia, ZrO_2 , and silica, SiO_2 . Gem zircon has a hardness of 7-7.5 and the highest specific gravity (4-4.8) of any commercial gem. When zircon is heated with soda, lime, or potash in the presence of acids, zirconates are formed. Zirconium carbide is produced by heating zircon with carbon in an arc furnace: $ZrSiO_4 + 4C \rightarrow ZrC + SiO + 3CO$. The carbide melts somewhat above 3500° C and is extremely hard and refractory. It burns in air upon removal from the arc furnace, forming reasonably pure zirconium dioxide.

Zirconium tetrachloride, tetrabromide, and tetraiodide are manufactured industrially by reacting the respective halides with zirconium carbide in the presence of carbon. The trichloride and dichloride also exist, as do the corresponding bromides and iodides. The tetrahalides are all colorless crystalline compounds that sublime at about 300° C and above and, except for the tetrafluoride, readily hydrolyze to form the oxyhalides, such as $ZrOCl_2 \cdot 8H_2O$. Salts of the composition M_2ZrF_6 and M_3ZrF_7 , fluozirconates, are formed by the reaction of fluozirconic acid with alkalis.

Zirconium oxychloride or zirconyl chloride, $ZrOCl_2 \cdot 8H_2O$, is a colorless crystalline substance readily soluble in water and in alcohols. It is used in pharmaceuticals, in water repellents, and in the preparation of printing-ink pigments from acid dyes by precipitating these dyes from aqueous solution to form compounds of intensely colored solids.

Zirconium dioxide, or zirconia, is the only stable oxide under ordinary conditions, although ZrO and ZrO_3 are also known to exist. Zirconia is a white crystalline substance that melts at 2677° C and is extremely unreactive at room temperature. It finds use in resistors, enamel pigments, radiography, refractories, as an abrasive, and as a raw material in preparing metallic zirconium and zirconium compounds.

Hydrous zirconia, $ZrO_2 \cdot xH_2O$, is precipitated when alkali is added to a solution of zirconium salt. A number of uses result from its remarkable adsorptive and complexing properties. Hydrous zirconia precipitates urushiol, the active irritant of poison ivy, and is therefore useful in the treatment of poison-ivy dermatitis. It is also used in deodorants.

There are many compounds in which oxygen or nitrogen form a link between zirconium and carbon. Zirconium tetracetylacetonate, the compound resulting from the chelation of acetylacetonate with Zr^{4+} , is a typical example of zirconium exhibiting a coordination number of 8. Coordination compounds of zirconium are used as catalysts for ammonia synthesis, organic oxidations and syntheses, esterifications, cracking, polymer-

izations, and in the conversion of sulfur dioxide to sulfur trioxide. Disulfate zirconylic acid is the best-known sulfate and is used in the tanning of leather and in the precipitation of amino acids.

Production. Metallic zirconium can be produced by the Kroll process, which involves the purification of zirconium tetrachloride by sublimation and the reduction of the tetrachloride vapor by molten magnesium. The van Arkel process gives a purer metal but is more costly and is not suitable for quantity production of metallic zirconium. It involves the dissociation of zirconium tetraiodide and the deposition of zirconium on a metal filament at about 1300° C. The deposited zirconium has high ductility but low tensile strength.

Unless special separation methods are used in these processes, the zirconium produced contains from .5 to 3 percent hafnium, the reason being that zirconium and hafnium have very similar properties and always occur together in nature. Zirconium can be separated from hafnium by means of various processes. These separation methods include fractional distillation, fractional crystallization, column chromatography, and solvent extraction.

ZITHER, zith'ər, a musical instrument native to Austria and southeastern Germany. It consists of a flat wooden sound box across which from 30 to 45 strings are stretched. It is played in a horizontal position, placed on a flat surface or held on the player's knees. The four or five strings closest to the player are stopped by being pressed down against a fretted board by the player's left thumb; they are plucked with a plectrum

BROWN BROTHERS

The zither.

attached to the right thumb. The other (open) strings are plucked by the three middle fingers of the right hand to supply a wavering accompaniment. The name "zither," which like "guitar" is derived from the Greek *kithara*, also is applied to one musicological classification of the plucked stringed instruments otherwise referred to as psalteries, as distinct from the somewhat similar dulcimers, which are struck with small hammers. The Hungarian Gypsy cimbalom, which is often commonly thought of as a zither, is in reality a large dulcimer.

HERBERT WEINSTOCK
Coauthor of "Men of Music"

ZITTAU, tsit'ou, a town in East Germany, on the west bank of the Neisse River, near the borders of Czechoslovakia and Poland. It is situated 50 miles (80 km) east of Dresden. Its industries

include cotton spinning and the manufacture of dress goods, iron-founding machinery, small motorcars, and radios. Zittau lost its coal mines when the territory east of the Neisse River was placed under Polish administration in 1945. The city was partly destroyed in the Thirty Years' War (1618-1648) and the Seven Years' War (1756-1763). Still standing are the Cross Church (Kreuzkirche) of 1410, the Peter-Paul Church of the 14th century, and a Renaissance building housing the library and museum. Zittau dates back to 1238 and was chartered in 1255; it became part of Saxony in 1635. After World War II it was included in the German Democratic Republic (East Germany), from 1952 in Dresden District. Pop. (1983) 40,983.

ZIZANIA, zĕ-zā'nĕ-ă, a genus of three species of grasses. They include the wild or Indian rice of North America, *Zizania aquatica*, the grains of which were used as food by the Indians and are still sold commercially; the Asiatic *Z. latifolia*, the thickened stem bases of which serve as a vegetable; and *Z. texana*, the Texas wild rice, found only around San Marcos, Texas. See also GRAIN; RICE.

EDWIN B. MATSKE.

ŽIŽKA, zhĭsh'kă, Jan, Bohemian general and Hussite leader; b. Trocnov, Bohemia, c. 1358/1360; d. Pribyslav, Oct. 11, 1424. The name Žižka (One-Eyed) probably was given to him when he lost an eye in childhood. After serving in the feudal bands of various lords, he went to Poland with the army sent by King Wenceslas IV of Bohemia to fight the Teutonic Knights, and distinguished himself in the victory of Tannenberg (1410). On his return he remained at court as one of Wenceslas' favorites and became an adherent of the church reform advocated, among others, by Jan Hus (q.v.).

After Wenceslas' death (1419), the Czechs repudiated Sigismund, the Holy Roman emperor, as heir to the Bohemian throne; but the atmosphere in Prague was conciliatory, and Žižka and his friends left for the more uncompromising city of Plzeň (Pilsen). Within a year, he and some 400 fighting men and their families had established themselves on the fortified hill that they called Tábor, and Žižka became the revolutionary military commander of the armed brotherhood of Taborites, who held that the "law of God" must be defended by the sword against its enemies and accordingly assumed the name of "warriors of God" (see also HUSSITES). Žižka proved a resourceful and imaginative military leader. He used wagons with guns mounted on them as mobile defensive strong points and on at least one occasion employed them as tactical offensive vehicles.

In 1420, when Sigismund besieged Prague with a large army, Žižka, with a much smaller force, occupied the heights called Vítkov and defended them so successfully that Sigismund withdrew without attempting to take the city; since then, the heights have been known as Žižkov. Žižka continued to campaign, although he was nearly or totally blind after being wounded in his remaining eye at the siege of the castle of Rábi in 1421. He defeated Sigismund at Plzeň and early in January 1422 at Kutná Hora and Německý Brod.

In 1423 there occurred a break between Žižka and the Taborites for reasons still variously ex-

plained, and he took command of another center of radical Hussitism in eastern Bohemia around Hradec Králové, but known from its mountain fortification as Horeb. In the civil wars that followed, Žižka won several victories, notably at Malešov (June 7, 1424), over the Prague party. He died of the bubonic plague at the castle of Pribyslav and was buried at Hradec Králové, but when his forces, which assumed the name of Orphans, lost control of that city, his relics were transferred to Čáslav.

MATTHEW SPINKA,

Waldo Professor of Church History, Emeritus,
The Hartford Seminary Foundation,

ZIZYPHUS, zĭz'ə-fəs, a genus of some 100 species of tropical and subtropical shrubs or trees, mostly Asiatic and Mediterranean, in the buckthorn family, Rhamnaceae. The best-known species, *Zizyphus jujuba*, is the common jujube, a usually spiny shrub or small tree, up to 30 feet in height. It has alternate, oval, finely toothed, 3-veined leaves, 1 to 2 inches in length, and small yellow flowers with 5 sepals, 5 petals, 5 stamens, and 1 pistil. This ripens into a dark red, oval drupe about the size of a green olive. The species occurs from the eastern Mediterranean region to China and Japan, and is widely cultivated to a limited extent also in warmer parts of the United States. The fruits are edible, and they are also used medicinally in cough medicines. The bark and leaves are utilized in tanning, while in Asia the leaves of the zizyphus serve as food for silkworms, and the lac insect thrives on the twigs.

Z. mauritiana, a related species native to Asia, Africa, and Australia, has broader leaves, densely hairy on the lower surface. It is also cultivated, in numerous varieties, for its fruits, which are often known as "Chinese dates" and are eaten either fresh, dried, or candied. The red hard durable wood of both of these species is commercially important.

Z. lotus is a smaller-leaved shrub of the Mediterranean area. Its edible fruits are not as large, and they may have been the lotus of the lotus-eaters of antiquity. *Z. spina-Christi* is a small thorny tree of northern Africa and western Asia. Either its twigs or those of a related genus, *Paliurus*, were probably used in the crown of thorns that Christ was forced by his tormentors to wear. A Brazilian species, *Z. joazeiro*, grows in dry places, and its fruits furnish food for domesticated animals.

EDWIN B. MATSKE,

Professor and Chairman, Department of Botany,
Columbia University.

ZLAToust, zlá-tŭ-ōōst', city, USSR, in Chelyabinsk Oblast of the Russian SFSR, in the southern Ural Mountains, 75 miles west of the city of Chelyabinsk. Situated on the Ay River, where it turns west to cut through the Urals, Zlatoust has rail connections with Chelyabinsk and the oil city of Ufa to the west. The city was founded in 1754 in conjunction with the building of the Kosotursk (later Zlatoustov) ironworks, and is noted for its quality metallurgy and machinery manufactures. It is claimed that the art of engraving on metal was first developed in Zlatoust early in the 19th century. The city was the home of the Russian metallurgist Pavel Petrovich Anosov (1797-1851), who developed a new method of obtaining quality steel. Before 1917 Zlatoust

produced small amounts of fine steel, and the facilities were enlarged considerably during the 1930's. During World War II the city was a major supplier of high quality alloy steels for Soviet aviation and other war industries. It also produces instruments, machine tools, and parts for agricultural machines, as well as abrasives and chemicals. Pop. (1959) 161,000.

W. A. DOUGLAS JACKSON.

ZNOJMO, znoi'mô (Ger. ZNAIM), city, Czechoslovakia, near the northern border of Austria, on the Dyje River, 35 miles southwest of Brno and 42 miles north-northwest of Vienna. It is a manufacturing center, with processing plants for fruit and vegetables from the surrounding countryside, and pottery and stoneware factories. Founded in 1226, the city has a Romanesque castle dating from the 13th century, a 14th century Gothic church, and a 15th century town hall. An armistice between France and Austria was signed here in 1809. Pop. (1957) 22,681.

ZOANTHARIA, zô-ən-thă-rē-ə, a subclass of Actinozoa (q.v.; Anthozoa) characterized by the fact that the tentacles are simple and unbranched, that there are usually incomplete as well as complete mesenteries, and that the tentacles usually alternate in several circles. The mesenteries and tentacles are often arranged in multiples of the number six, but this is variable, and in some forms the number of mesenteries increases during the growth of the animal. The animal develops as a gastrula, the blastopore of which remains as the mouth. The larva is usually ciliated and free swimming. The Zoantharia include the sea anemones and corals; these do not represent natural divisions of the class, but merely modes of life of its members: a colonial zoantharian with a calcareous exoskeleton is a coral; an isolated zoantharian without an exoskeleton is a sea anemone. See also CORAL AND CORAL REEFS; SEA ANEMONE.

ZOBEIR RAHAMA PASHA, zô-bîr' ră'mă pâ'shă, Egyptian pasha in the Sudan: b. 1830; d. Geili, Sudan, Jan. 5, 1913. His family claimed descent from an uncle of Mohammed. By 1860 he was a powerful slave trader along the White Nile and in the Province of Bahr el Ghazal. Zobeir maintained a private army in the area and, after crushing an attempt from Khartoum to subdue him, was made governor of the province in 1869. In 1874 he conquered Darfur for the khedive of Egypt, but when he went to Cairo in 1876 to seek the governorship of the conquered region, he was detained by the authorities. Meanwhile, his son Suleiman, instigated by Zobeir, took up arms against Gen. Charles George Gordon, newly appointed governor general of the Sudan, who was moving against the slave trade. Suleiman was captured and executed, but in 1884, when the Mahdist movement threatened, Gordon suggested that Zobeir should be appointed his successor as an expedient to halt the revolt. The British government refused to accept the former slave trader, and in 1885 he was arrested on charges of treasonous dealing with the Mahdi and deported to Gibraltar. He returned to Egypt in 1887, and after 1899 was allowed to live on his estates in the Sudan.

ZODIAC, zô'dē-āk, an artificial belt on the celestial sphere extending 8° on either side of the

ecliptic (q.v.). It is arbitrarily subdivided into 12 equal sections, 30° long, which bear the names of the zodiacal constellations. These sections, or *signs*, are traversed successively by the sun in its apparent annual motion. The moon and planets, except Pluto, never stray more than 8° from the ecliptic; thus they also remain within the zodiac. Counted eastward from the vernal equinox, the signs are Aries (the Ram); Taurus (the Bull); Gemini (the Twins); Cancer (the Crab); Leo (the Lion); Virgo (the Virgin); Libra (the Balance); Scorpius (Scorpio; the Scorpion); Sagittarius (the Archer); Capricornus (the Goat); Aquarius (the Water Carrier); and Pisces (the Fishes).

The signs of the zodiac.

The names of the zodiacal constellations are very ancient, dating from the early Babylonian period and possibly from the Sumerians, except Libra, which was originally a part of Scorpius called Chelae (the Claws). The zodiac itself, on the contrary, is a mathematical concept which does not appear to have been in use prior to 400 B.C. Its purpose was to provide a frame of reference in which the positions of the sun, moon, and planets could be expressed by their angular distance from the beginning of the sign in which they were located. This device was used only in calculating predicted positions; in actual observations, positions had to be measured with respect to known bright stars, because the subdivisions of the zodiac have no visible counterpart in the sky.

About 100 B.C. it became the established practice to place the beginning of Aries at the vernal equinox. (For that reason the term "First of Aries" is still used occasionally as a synonym for vernal equinox.) This unfortunate choice played a decisive part in the eventual disuse of the zodiac for astronomical purposes. The equinoxes are located at the intersections of the celestial equator with the ecliptic; the position of the celestial equator, in turn, depends on the location of the north celestial pole, that is, on the orientation in space of the earth's polar axis. Because the earth is not perfectly spherical, its polar axis undergoes a slow movement of preces-

D.E. Blackwell and M.F. Ingram

Zodiacal light. The streaks show paths of stars across the fixed-camera field during a 10-minute exposure.

sion, which causes a corresponding displacement of the equinoxes, westward along the ecliptic, amounting to about 1° in 70 years (see also **PRECESSION OF THE EQUINOXES**). Accordingly, the zodiacal signs no longer coincide with the zodiacal constellations of the same name, and the First of Aries is now located in the western part of the constellation Pisces. The zodiac is no longer of practical use in astronomy.

See also **ASTRONOMY; CONSTELLATION;** and separate articles on individual constellations.

SIMONE D. GOSSNER

ZODIACAL LIGHT, zō-dī'ā-kəl līt, a luminous band of the celestial sphere, confined to the region of the zodiac (q.v.). Extremely faint, it is visible in the west immediately after sunset and in the east shortly before sunrise, in the form of a pyramid of light whose brightness decreases with increasing distance from the sun. The extent to which it may be traced depends on the observer's acuity of vision; on the average, it is seldom seen beyond 45° from the sun. At intermediate latitudes it is observable only when the zodiac reaches its greatest elevation above the horizon, in the evening sky in early spring and in the morning sky in early autumn. At all other times it is too close to the horizon and is dimmed beyond the limit of visibility by haze and dust. In the tropics, where the zodiac is nearly vertical throughout the year, it may be observed at all seasons.

Spectroscopic observations have proved that the zodiacal light is not self-luminous. It arises from the reflection and diffraction of sunlight by myriad small particles scattered through the entire solar system. Hendrik C. van de Hulst has shown that its observed brightness may be accounted for by assuming the existence of a cloud of particles 0.04 inch in diameter, spaced 5 miles apart on the average. The cloud is disc-shaped and coincides approximately with the plane of the ecliptic (q.v.); its estimated thickness is about one tenth the diameter of the earth's orbit. Particles of that size, receiving heat from the sun and radiating it back into space, gradually spiral

in until they fall into the sun (Poynting-Robertson effect). Therefore, the particles that currently produce the zodiacal light must be of relatively recent origin; they are presumed to come from the gradual disintegration of comets and the dust produced by the continuous grinding of asteroids.

SIMONE D. GOSSNER

ZOE, zō'ē, empress of the Eastern Roman Empire; b. 980; d. 1050. A daughter of Emperor Constantine VIII, she succeeded to the throne on his death in 1028 and took a consort who shared the throne with her as Romanus III Argyrus. In 1034 she caused Romanus to be murdered with the aid of her paramour Michael the Paphlagonian, whom she then married and brought to the throne as Michael IV. Michael died in 1041 and was succeeded as coruler by his nephew Michael V Calaphates, whom Zoe had adopted. He imprisoned the empress and seized sole power, but was deposed in a revolt in 1042. Zoe then reigned briefly with her sister Theodora, who was a nun, but later in 1042 she took another husband, who as Constantine IX Monomachus ruled the empire jointly with both sisters until Zoe's death and then with Theodora alone until his own death in 1055.

See also **CONSTANTINE IX; MICHAEL** (emperors of the Eastern Roman Empire); **ROMANUS**.

ZOFFANY, zōf'ā-nē, **John**, Bohemian painter working chiefly in England; bap. Frankfurt am Main, Germany, March 15, 1733; d. near Kew, Surrey, England, Nov. 11, 1810. Precociously gifted, he worked in Italy and Germany before going to England about 1758. Here he came close to starvation until Benjamin Wilson, a portraitist, hired him to paint draperies at £40 a year. David Garrick seems to have been his first considerable patron. The 3d earl of Bute presented him to George III, and a long series of single portraits or conversation pieces devoted to the royal family resulted. Nobility and gentry, besides many actors, sat for him. In 1762 he became a member of the Society of Artists. He was a founding member of England's Royal Academy in 1768.

Sent to Florence by the king in 1772, Zoffany worked for two years to perfect his most famous conversation piece, *Tribuna*—the horizontal room of the Uffizi Gallery, crowded with notable Englishmen, among them Zoffany himself showing a "bargain" to Lord Cowper. This amusing pictorial document was bought by Queen Charlotte shortly after the painter's return (1779) and is now at Windsor. Zoffany had been made a baron of the Holy Roman Empire earlier in 1779. From 1783 to 1790 he was in India, with disappointing results. He redeemed himself (1790) with *Charles Towneley and His Friends in His Library* (Lord O'Hagan's collection), a piece comparable to the *Tribuna*. In the mid-1960's the best Zoffanys were still in private hands, aside from those in the royal collection. Some of his other works are in the National Portrait Gallery, London; and in Edinburgh, Glasgow, and Oxford.

WALLACE BROCKWAY

ZOG I, zōg, or **ZOGU I**, zōg'wə (original name **AHMED BEY ZOQU**), king of Albania; b. near

Burgayeti, Albania, Oct. 8, 1895; d. Suresnes, France, April 9, 1961. The son of a Muslim chieftain of the Zogolli clan in the Mati district of central Albania, he was educated at military schools in Monastir, Turkey (now Bitolj, Yugoslavia), and Constantinople (Istanbul), and was prominent in the Albanian struggle for independence in 1912-1914. Forced to flee when World War I began, he fought as an officer in the Austrian Army. In 1920 he was named minister of the interior in Albania's postwar provisional government and, as head of the national police, repelled the invading Yugoslavs. As minister of the interior again in 1921-1922, he crushed an internal revolt. Zogu became premier in December 1922 but was ousted and driven into exile early in 1924 by Bishop Fan Noli, head of the Albanian Orthodox Church. In December, however, Zogu returned to Albania to lead a successful military coup against Noli, and was chosen as the president of the Albanian republic by Parliament in January 1925. In 1928 he was proclaimed king with the title of Zog I.

An autocratic ruler, Zog undertook a program of public works with financial aid from Italy, as a result of which the country fell more and more under Italian control. In April 1939 Italian forces invaded, and Zog fled with his queen, the former Countess Geraldine Apponyi of Hungary, whom he had married in 1938, and their infant son. During World War II the family resided in England. The king was formally deposed in *absentia* in January 1946 by the new Communist-dominated Albanian regime and eventually took up residence in France. His son Skander (Prince Leka; b. 1939) succeeded him as pretender to the Albanian throne.

See also ALBANIA—History.

ZOHAR, zō'här (Heb. for "splendor"), the sacred book of the Jewish Cabalists (see CABALA), written in Aramaic, ascribed to the "divine saint," Rabbi Simeon ben Yohai (2d century A.D.), but actually written or compiled by the Spanish Cabalist Moses de Leon toward the end of the 13th century. Most of it has the form of a commentary on the Pentateuch, Song of Songs, Ruth, and Lamentations, and is permeated by a mystical spirit, often strongly erotic in its imagery (for example, the description of the love between God, the bridegroom, and Israel, the bride, with the Temple of Jerusalem as their bridal chamber), resembling in this respect some of the contemporary Spanish Roman Catholic mystics. Every passage or word in the Bible is, for the Zohar, a mystery (*raza*), and this term occurs many times on each of its pages. It also contains mystic revelations received by Simeon ben Yohai, stories of his death, descriptions of the world, of paradise and hell, Messianic speculations, a detailed angelology and demonology, and discussions between the alleged author, Simeon ben Yohai, and "the faithful shepherd" (Moses) about such matters of spiritual interest as the Heavenly Academy.

The Zohar's impact on Judaism became pronounced only after the expulsion of the Jews from Spain in 1492. It was felt in the subsequent pseudo-Messianic movements of the 16th and 17th centuries, and reechoed in the Hasidism of the 18th century. Hasidic Jews still study it and regard it as a holy book. Numerous commentaries have been written on it, and it was translated in the 18th century into Latin and Hebrew and

in the 20th century into English (5 vols., 1931-34).

RAFAEL PATAL,
Director of Research, Theodor Herzl Institute,
New York City.

ZOILUS, zō'a-las, Greek rhetorician and literary critic: fl. 4th century B.C. A native of either Amphipolis or Ephesus, Zoilus was so celebrated for the asperity with which he assailed Homer for introducing fabulous and incredible stories into his *Iliad* and *Odyssey* that he was nicknamed *Homeromastix* (Scourge of Homer). He also attacked the rhetorician Isocrates and the philosopher Plato, his contemporaries. The term "Zoilism," denoting carping criticism, is derived from his name. Zoilus' writings, of which only scanty citations survive, included, besides the diatribes against the above-mentioned authors: *Peri schēmātōn* (On Figures of Speech); *Peri Amphipoleōs* (On Amphipolis), in three books; *Tenediōn enkōmion* (Encomium on the Tenedians); and *Historia apo theogoniās heōs tēs Philippou teleutēs* (History from the Theogony to Philip's Death), a history from the creation of the world to the death of King Philip II of Macedon (336 B.C.).

P. R. COLEMAN-NORTON.

ZOISITE, zoi'sit, a mineral closely related to epidote (q.v.), named by Abraham Gottlob Werner in 1805 in honor of Baron Sigismund Zois von Edelstein (1747-1819), who discovered it. It is a basic orthosilicate of calcium and aluminum, $\text{HCa}_2\text{Al}_2\text{Si}_2\text{O}_{13}$. The aluminum is sometimes partly replaced by iron, the mineral thus approaching epidote in composition. Though its crystals are orthorhombic, their form is very similar to the monoclinic epidote. Its hardness is 6 to 6.5 and specific gravity about 3.3. Its color is usually dull gray or brown, but in the variety thulite, found in Norway, it is a beautiful rose pink. Zoisite is found in many European localities and also abundantly in the New England states, Pennsylvania, and North Carolina, and in exceptionally good crystals at Ducktown, Tenn.

ZOLA, zō'la, Fr. zô-lá', **Émile (Édouard Charles Antoine)**, French novelist: b. Paris, France, April 2, 1840; d. there, Sept. 29, 1902. His development as a writer began during his youth at Aix, where he and his friend Paul Cézanne started out by imitating the romantics. His widowed mother wanted him to study law, but he failed to win his baccalaureate and in 1860, after two months as an ill-paid clerk on the Paris docks, abandoned himself for a year and a half to the garret life of an impoverished poet. This attempt at verse ended in failure and was followed by a period of reaction to romanticism and further growth in the direction of realism. As a publicity chief at Louis Christophe Hachette's bookshop, he learned what made writing sell. As a vigorous literary columnist and art critic on *Cartier de Villemessant's* newspapers, he mastered the techniques of sensational journalism. In 10 formative years he wrote numerous short stories and essays, 4 plays, 2 long pieces of commercial fiction, and 3 serious novels—*La confession de Claude* (1865), *Thérèse Raquin* (1867), and *Madeleine Féral* (1868).

Influenced by Honoré de Balzac, Stendhal, Gustave Flaubert, and Hippolyte Taine, Zola formulated his aesthetic principles, including his

definition of art as "nature seen through a temperament." He further expressed his belief that true artistic originality can best be achieved only by a rejection of tradition and a total submission to the life of one's own times, and he was convinced that science offers the writer a

Émile Zola

The Bettmann Archive

superior method of approaching reality. In 1868, armed with these ideas, he submitted to his publisher the plan for a group of novels, *Les Rougon-Macquart*, portraying the fortunes of a family under the Second Empire and through this frame the whole turmoil of his age. At first limited to 10, the series ultimately comprised 20 volumes (see *ROUGON-MACQUART, LES*), ranging in subject from the world of peasants and workers to the imperial court, and in type from shocking exposés to lyrical fantasies and sustained epics. Yet, although he liked to astonish the public with his virtuosity, his method of composition changed little over the years. First methodically assembling his research data, plot ideas, and character sketches under separate analytical headings, he then combined all this material in chapter plans with a complex art anticipating the techniques of film montage. Finally, with this scenario to guide him in the writing stage, he was free to concentrate on his style, which was remarkable for frequently rhythmic repetition, visual impressionism, and force.

Starting with the publication of *L'assommoir* (1877), a tragic study of life in the Paris slums, Zola became world famous, bought an estate at Médan, and attracted imitators and disciples. From 1879 to 1882, to consolidate his success, he waged a lively publicity campaign supporting naturalism. Inspired by Claude Bernard's *Introduction à la médecine expérimentale* (1865), he even wrote a treatise (*Le roman expérimental*, 1880) picturing the naturalist author as a scientific observer following his fictional human guinea pigs through lifelike situations and thereby verifying certain psychological and social hypotheses. Yet, despite such efforts to build a public image of himself as a scientist, he was at his best, not when trying to apply specific scientific or pseudoscientific theories, but when giving imaginative expression to the new subjective vision of reality that modern science and technology had helped shape.

Essentially, like other great realists, Zola was an "illusionist" who excelled at imposing his intuition of the world under the guise of plain, unvarnished fact. This method may be seen in *Germinal* (1885), generally considered one of his finest works. The first major novel on a strike,

it may be appreciated either as a factual social document or as a prose epic, a lurid yet sublime "poem," in which his research notes on class warfare and labor conditions in the coal mines grow into dreamlike symbols and Dantesque descriptions often bordering on hallucinations. As elsewhere in his novels, objects are brought to monstrous life, animals assume human traits, crowds become forces of nature, and individual characters are transformed into types, allegories, and symbols. Underlying this synthesis of realism and symbolism, which is the triumph of Zola's art, are the poetic themes which provide the *Rougon-Macquart* novels with their deepest unity: above all, a sense of cosmic upheaval, of world destruction and renewal involving a cyclical view of history and a materialist philosophy in which little remains of the Christian-humanist tradition. It is a philosophy in which, as Jules Lemaitre said, "men appear like waves on a sea of darkness and unconsciousness."

After the enormous *Rougon-Macquart* project, Zola undertook to expound his social gospel based on a creed of hard work and justice in a trilogy (*Les trois villes*, 1894-98) and an unfinished tetralogy (*Les quatre évangiles*, 1899-1903); but never again attained the power of such masterpieces as *L'assommoir* and *Germinal*. On Jan. 13, 1898, he went to the defense of Capt. Alfred Dreyfus by publishing in *L'aurore* a letter, "J'accuse," pointing out irregularities in Dreyfus' trial and making charges that practically forced the government to prosecute him, an expedient that achieved its purpose in reopening the Dreyfus case and led to the complete vindication of that officer. In February 1898 a verdict imposing imprisonment and fine was brought against Zola, but it was quashed by the Cour de Cassation on April 2. A second trial was called and Zola, his purpose accomplished, decided not to appear and went to England, where he remained until an amnesty permitted his return to France. He died of asphyxiation caused by fumes from a blocked chimney in the bedroom where he was sleeping.

At Zola's funeral, Anatole France declared, "He was a moment of the human conscience." Zola had been repeatedly refused admission to the Academy, and after his condemnation in 1898 he was removed from the roll of the Legion of Honor, but in 1908 his remains were transported to the Panthéon. Although still famous chiefly as the main exponent of literary naturalism, he has undergone since about 1950 a general critical reevaluation emphasizing his powerful imaginative qualities.

ZÖLLNER, tsôl'nar, **Johann Karl Friedrich**, German astrophysicist: b. Berlin, Germany, Nov. 8, 1834; d. Leipzig, April 25, 1882. He was educated at Berlin and Basel, and in 1866 was appointed professor of physical astronomy at the University of Leipzig. His numerous contributions to astronomical science included studies of comets, the constitution of the sun, and the thermal conditions of planets. Zöllner's studies of the albedo (ratio of light reflected to light received, or power of reflection) of the moon facilitated the later comparison of the brightness of the moon and the sun.

Zöllner is best known for his invention of an artificial star or comparison photometer. Among its many applications, this instrument for the first time made possible systematic and accurate visual determinations of the magnitudes of stars, and between the years 1885 and 1905 it was used at the Potsdam Observatory to compile the first great photometric catalog of bright stars in the Northern Hemisphere. With the new instrument Hermann Karl Vogel later obtained the first spectroscopic proof of the rotation of the sun by comparing the spectra of its opposite edges and thus confirmed the existence of the Doppler effect. In his later years Zöllner engaged in metaphysical speculations, studies of spiritualism, and investigations of hypnotism that aroused considerable controversy.

ZOLLVEREIN, tsôl'fə-rin, the German word for "customs union." In 1815, with the establishment of the German Confederation, Prussia received Westphalia, part of Saxony, and most of the territory on the left bank of the Rhine in recognition of her contribution to the campaigns ending at Waterloo. Although this seemed small reward for her prodigious efforts in the Napoleonic Wars, it enabled her once more to become one of the great European powers. However, the creation of Prussian provinces in the west separated from the main body of Prussia in the east posed great economic problems. In conveying goods to south Germany, Prussia found herself hampered by the wide variety of tariff schedules and currencies of the intervening states. Bankers and businessmen were gradually convinced that trade could be facilitated only by the abolition of local customs and that thus the cost of tariff collection could be reduced and smuggling curbed. The flooding of German markets with cheap British goods was another factor persuading Prussia's industrial leaders that the tariff must be completely reformed. A major influence leading to the formation of a customs union was the desire to help the landholders by establishing markets for their produce and in enlarging the areas in which the products could be sold.

The Prussian state was economically unified by the law of May 26, 1818, that superseded 67 provincial tariffs and became the basis of German economic policy for more than 60 years. This law, founded on free-trade principles, inspired by the philosophy of Adam Smith, and dictated by Prussia's peculiar needs, established against the rest of the world a low tariff on manufactured goods and one still lower on raw materials. However, since it taxed materials and manufactures transported through Russian territory, it served to influence her neighbors to join the union and thus, while avoiding its penalties, share in the benefits it exerted in encouraging foreign and domestic trade and in elevating the standard of living without

destroying industry's ability to compete abroad. Successful in unifying her own economic sphere, Prussia determined to extend the system. Indeed, the minister of finance, Friedrich Adolf von Motz, envisaged Prussia as the leader of a customs union embracing all of central Europe and by cajolery and economic pressure worked to advance toward this goal.

Overshadowed by Prussia, the smaller states of north and central Germany, especially those enclaved by their neighbor, were compelled to choose between federation and economic starvation. The first of these states to abandon an economic policy of its own signed a tariff treaty with Prussia in 1819, and others of the smaller states followed its example in the next seven years. The remaining German states, especially those in the south, regarded the new union with envy and Prussia's growing power with suspicion. Hoping to maintain their economic independence while reaping the fruits of collaboration, Bavaria, Württemberg, and Hohenzollern in 1827-1828 established an independent customs league, which differed from the Prussian system in that its members retained full sovereignty. A few months later Saxony, Hesse-Cassel, and Hannover initiated the formation of the Middle German Union, whose members agreed to join none of the rival associations. In 1834 Hannover, Brunswick, and Schaumburg-Lippe formed still another organization, the *Steuerverein*, or Tariff Syndicate. This multiplicity of unions, however, reduced only partially the numbers of sovereignties in economic conflict and this, joined to Prussian economic and political pressure, resulted as early as 1829 in economic collaboration between the groups in the south and east. Within a few years defectors from the earlier associations had become so numerous that Prussia felt sufficiently strong to promulgate the *Deutscher Zollverein*, or German Customs Union, on March 22, 1833, to begin operations on Jan. 1, 1834. Initially, the union comprised 26 million people and 80 percent of the territory that was to form the German Empire after 1871; the four principalities that held aloof had all joined the confederation at the time of the Franco-Prussian War, when Alsace and Lorraine were also embraced. Hamburg and Bremen refused to relinquish their advantages as free ports, but capitulated in 1888.

The charter of Germany's economic unification provided for continuous consultation among the states, division of revenues according to population, free entry for raw materials, and low tariffs on manufactures. Wishing to destroy Austria's influence in the German Confederation and fearful of the dumping of the Hungarian grain crop into Germany, Prussia refused admission into the *Zollverein* to Austria, which then united the Habsburg monarchy into an independent customs district, despite the desire of the lesser German states to effect unification to extend their own commercial sphere and thus relieve Prussian pressure. Austria was partially satisfied with a commercial treaty, terminated by the war of 1866.

The *Zollverein* exerted a powerful influence in other countries. After 1860 Napoleon III cut French import duties in a treaty with England and negotiated low tariff agreements with the German Customs Union and with seven European countries. This era of free trade came to an end, however, when Austria and Italy raised duties in 1878 and when in the next year Bismarck decided that only higher tariffs could assure German in-

dustry a secure home market against British commercial penetration. Six years later Germany raised agricultural tariffs, leaving Britain as the only proponent of the liberal principles of free trade.

In retrospect, the *Zollverein* is seen as the first step taken to unite Germany under Prussian leadership; as a strong influence in the development of the industrial Ruhr and the growth of German armament; as the factor inspiring the development of an all-embracing railway network in conformity with the demands of industry's expansion; as the influence that transformed Germany's political union under Austria into economic unification under Prussia; and as the forerunner of the European Coal and Steel Community, the European Common Market, and similar plans for economic and political cooperation through the elimination of tariffs.

ZOMBA, zôm'bə, town, Malawi, capital of the republic, situated 20 miles west of Lake Chilwa, in Southern Province, on Shire Highlands, 37 miles northeast of Blantyre. The site, at the base of Zomba Mountain, lay close to the infamous slave route from the south end of Lake Nyasa to Mozambique. Yao chiefs repeatedly raided the area, selling its inhabitants to the Portuguese as slaves. Sir Harry Johnston, British commissioner for South Central Africa in 1891, established Zomba as capital of the Nyasaland Protectorate. In recent times diamond drilling has uncovered limestone deposits in the vicinity. There is also a cement works in the town. Cotton and tobacco are cultivated in the area, which contains an agricultural experiment station. The population at the 1966 census numbered 19,616 and included, besides Africans, a number of Europeans, Asiatics, and Coloreds.

JOHN RALPH WILLIS, JR.

ZOMBI or **ZOMBIE**, zôm'bē, a term, originally from West Africa, with several meanings. In Dahomey and the Congo *zumbi* or *zambi* means "god" or "fetish"; in Haiti and Louisiana the related deity is a python or other snake. A "conjure man" of the Haitian voodoo cult is said to have the power to steal a living man's soul, or to reanimate a corpse; the resulting monster is called a zombi. Emptied of the soul, the carcass may be sold for food; the walking corpse, dead in features and mechanical in action, may be hired out as a drudge. Stabbing the newly dead is a preventive, and feeding salt to the zombi a cure or quietus to the corpse; the former is an obvious precaution like spiking the heart of a Balkan vampire, and the latter may reflect the place of salt in Christian burial and baptismal services.

Though the separable soul is also a European or even universal concept, the details of zombi magic are clearly American importations from Africa. American slang has seized the vivid notion of the walking dead and uses the term to mean either a disagreeable and unwanted human being whom the "ingroup" wishes to ostracize, or a powerful rum drink which threatens to paralyze one's vital spirits.

FRANCIS LEE UTLEY.

ZONARAS, zôn'ə-rəs, Joannes, Byzantine theologian and chronicler: fl. 1120. Before 1118 he commanded the imperial bodyguard and was the principal imperial private secretary. Sometime after 1118 he became a monk and turned to literary pursuits. Among his theological treatises is the valuable *Exēgēsis tōn hierōn kai theiōn kanōnōn*, an exposition of canon law extracted from apostles, councils, and church fathers. In lexicography he produced *Synagōgē lexeōn syllogeisa ek diaphorōn biblīōn*, a lexicon listing obsolete and foreign words with their meanings in contemporary Greek. But his renown rests rather on his *Chronikon* or *Epitomē tōn historion*, in whose 18 books he compiled an annalistic history from the creation of the world to the death (1118) of Emperor Alexius I Comnenus. Its importance is that Zonaras has preserved frequently the very words of authors whose works no longer remain. Thus, for the lost portions of the *Rōmaika* (Roman History) of Dio Cassius (q.v.) we depend upon Zonaras' abstracts entirely for books 1-20 and partially, with Joannes Xiphilinus (q.v.), for books 44-80.

P. R. COLEMAN-NORTON.

ZONE, zôn, any encircling line, belt, or boundary, or any division, area, or layer separated from others in some natural or systematic manner. The word is derived from a Greek term for "girdle"; hence, in *mathematics*, a zone is that portion of the surface of a sphere cut off by two parallel planes (see *SPHERE*), since such a section girdles the sphere. The various *climatic zones* on the earth's surface, as the north temperate and torrid zones (see *ZONE*, *CLIMATIC*), are examples of strictly mathematical zones. A mathematical function involving a system of spherical coordinates that divide a sphere into zones is called a *zonal harmonic* (see *HARMONIC ANALYSIS*, *THE-Zonal Harmonics*).

From its basic mathematical meaning, the term "zone" has broadened to denote any section or area of the earth clearly marked off from its surroundings, whether the markings are parallel, converging, or even irregular, and whether the area so marked off is large or small. The boundary of any such zone, whether straight, curved, or irregular, is called the *zone line*. Among the most important are the *time zones*, north-south segments on the face of the earth indicating areas in which a fixed standard time is accepted. The boundaries are the converging meridian lines at sea and usually irregular lines on land. Time expressed according to such rules is *zone time*. See also *TIME*, *INTERNATIONAL ZONES OF*.

Sometimes an essential part of the definition is that the zone be clearly marked off. Thus, types of soil with clearly visible boundaries between layers (horizons) are classified as *zonal soils*, while others are *intrazonal* or *azonal soils* (see *SOIL-Soil Classification*). On the other hand, a zone may be as dimly marked off as the kind

used for aircraft guidance, the *equisignal zone*, which is the sector in which distinctive radio signals from two transmitting beacons may be received with equal intensities.

The areas marked off by a zone need not be on the earth itself. They can be under the sea, as the *abyssal* and *littoral zones*, the great depths and the shorelines, respectively. They can be under the earth's surface, as the *Eohippus zone*, which includes the stratum of fossiliferous rock characterized by the remains of *Eohippus*, the early, multitoed horse; or the *zones of rock fracture and flowage*, the latter representing the depths below the surface at which pressure causes rock to flow, rather than fracture. The area can even be in the atmosphere, as is the hollow sphere of the *anacoustic zone*, the atmospheric region above the 100-mile level in which the air is too thin to transmit sound.

The generalization of the term zone has made possible its wide use in many specialized senses. In *anatomy*, it may signify segments cut off by parallel or curved lines, a usage more in accord with the mathematical meaning, as in the three *abdominal zones*. It is also used for the irregular portion of the cerebral cortex that controls the motor nerves, known as the *motor zone* (see MOTOR AREAS). Again, the term may be applied to an entire spherical surface, as in *zona pellucida*, the clear membrane that envelops the ovum. An organism composed of similar segments, such as an earthworm or a centipede, may seem to be divided into zones and to display *zonal symmetry*, and a single segment is sometimes called a *zonite*. In *medicine*, the name *zona* is applied to shingles, or herpes zoster, an inflammatory disease that may encircle the torso like a girdle. The term may even refer to such an immaterial standard as the *comfort zone*, signifying the temperature range in which the human body neither shivers nor sweats.

In *crystallography*, faces parallel to the same edge form a zone, reminiscent of the parallel planes that mark off a zone on the surface of a sphere. The direction of the edge is the *zone axis*, and the poles of the faces parallel to the same edge lie upon a *zone circle*. The various parallel planes are numbered in a conventionally accepted manner, and these numbers, the *zone indices*, are used to characterize the crystal structure by means of a *zone symbol*. The mathematical relation expressing the common position of all the parallel planes with reference to the axes of the crystal is the *zonal equation*. Some crystals are made up of concentric shells of different composition, each following the general form of the crystal. Each of these forms a zone, since the zones of a sphere (in the mathematical sense) can appear as concentric shells or circles in two-dimensional projection. Such crystals are *zoned crystals* and are said to be *zonate* or to have *zonal structure*.

Electrophoresis occurs when particles are made to migrate in an electric field from their original positions in a solution or suspension. When the migration is conducted on moist paper from an original narrow zone, the result is a mixture of electrophoresis and chromatography that may be called either *zone electrophoresis* or *electrochromatography* (see CHROMATOGRAPHY—Partition Chromatography).

In *metallurgy*, an ingot may be refined by melting a narrow zone of its substance and moving this melted zone slowly along the length of

the ingot. Those impurities that are more soluble in the liquid phase of the metal than in the solid are carried along, and those that are less soluble in the liquid are left behind, so that the central portions of the ingot are purified. This is called *zone refining*, while the motion of the molten area is known as *zone travel*. Where molten zones passing back and forth along the ingot are used to render the substance homogeneous by diminishing differences in composition, the process is known as *zone leveling*. Zone melting is also used to purify crystals or to redistribute their impurities.

In *optics*, diffraction patterns are divided into *Fresnel zones*, named for the French physicist, Augustin Jean Fresnel, who analyzed the phenomenon in mathematical detail. A transparent plate, known as a *zone plate*, marked off into a series of concentric zones of fixed widths, with alternate zones blackened, makes use of Fresnel zones to act as a strong focusing device.

For zones in municipal and county planning, see the article ZONING.

ISAAC ASIMOV,
Associate Professor of Biochemistry, Medical
School, Boston University.

ZONE, Climatic, a portion of the earth bounded by parallels of latitude and characterized by a distinctive climate. The torrid zone extends from the equator to the tropics of Cancer and Capricorn at $23\frac{1}{2}^{\circ}$ north and south latitudes, respectively. The two frigid zones extend from the poles to the Arctic and Antarctic circles at $66\frac{1}{2}^{\circ}$ north and south latitudes, respectively. Between the frigid and torrid zones lie the north and south temperate zones.

In the torrid zone the midday sun is high above the horizon throughout the year, and the atmosphere receives more heat from the sun than it loses to space by its own radiation. In the frigid zones the radiational cooling of the atmosphere is larger than the meager heating supplied by the sun, which is never far above the horizon and is altogether absent much of the winter. Consequently perpetual warmth bathes the torrid zone while bitter cold in the frigid zones is interrupted only by a brief, mild summer. The extremes of temperature in these two areas are not as great as they might be, for the differences of heating and cooling set the atmosphere in restless motion. The resulting winds transport some of the tropical heat poleward and some of the Arctic and Antarctic cold equatorward across the intervening north and south temperate zones, so that thermal equilibrium is maintained in all the zones. The actual climates of the various zones are therefore determined partly by solar and atmospheric radiation and partly by the modifying effects of air motion.

In the torrid zone, and in the adjacent fringes of the temperate zones, the air flows quite steadily, mainly from east to west. This flow, the trade wind, provides welcome ventilation in a climate that would otherwise be uncomfortably warm and humid. The trade winds of each hemisphere converge gently toward the equatorial region, where compensating upward currents cool to provide extensive cloudiness and heavy rainfall in the moisture-laden air. At the poleward limits of the trade winds, compensating downward air currents inhibit clouds and rain, particularly over the continents, where the great deserts of Africa, Arabia, Australia, and western North America are

found. Here the relentless impact of summer sun on sandy soil produces the world's highest temperatures, while winters are quite cool. Rainfall is so sparse that irrigation is necessary for effective agriculture.

Over the temperate zones the rotation of the earth about its axis becomes effective in creating a different, chaotic regime of winds in which the average air motion is from west to east. Alternating surges of polar and tropical air clash in migratory storms that range as far as the edges of the frigid zones. The resulting climate, in which the most highly developed civilizations have grown, is a changeable and invigorating environment in which the frequent storms ensure abundant rainfall. Within the frigid zones the climate is relatively quiescent, though the effects of storms from the temperate latitudes are felt intermittently. On the perpetual ice sheets of Antarctica and Greenland, temperatures remain below freezing all year and sink in winter to the world's lowest levels.

Striking east-west differences of climate within a zone occur where sectors of continent and ocean alternate. In the north temperate zone, dryness and extremes of summer heat and winter cold characterize the interior portions of Asia and of North America, while relative uniformity of temperature and frequent rain prevail over the oceanic sectors. Southeast Asia, though lying in the latitude of deserts, experiences the world's heaviest rainfall as the steady summer monsoon wind from the adjacent ocean is forced to ascend the massive mountain barriers of that region.

The limits of the climatic zones are not irrevocably fixed. The boundaries oscillate poleward in summer and equatorward in winter. Moreover, evidence of marked climatic variations in the distant past is abundant in the geological record. Proposed explanations of these variations have included expansion and contraction of the zonal climatic boundaries as well as displacement of the poles and drift of the continents.

FREDERICK SANDERS,
Associate Professor of Meteorology, Massachusetts
Institute of Technology.

ZONING, zōn'ing, in general, the process of dividing a larger area into smaller units. Hence, in government and business, there is zoning for postal delivery service, for determining attendance at public schools, for setting speed limits on highways, for computing railroad and trucking rates, and for any number of other purposes. In both common and legal usage, however, the term "zoning" by itself has come to refer almost exclusively to the legislative act of dividing a county or municipal unit into districts for the purpose of regulating land use and buildings therein.

Zoning regulations are distinguished from other local ordinances such as building, fire, health, and housing codes. Building and fire codes relate to the manner in which a building is constructed, to assure that it is sound and reasonably safe from accidental fire and other hazards. Health and housing codes relate, in general, to assuring that buildings are maintained according to minimum standards of healthfulness and sani-

tation. Zoning, on the other hand, typically divides all land into several classifications each for residential uses, commercial uses, and industrial uses so that each function of the community will have a proper amount of land in a location suitable to its needs and so placed as to be as compatible as possible with the uses around it. Zoning also controls lot sizes, the bulk and height of buildings, and the setbacks, yards, and open spaces to be established on a lot. This is done in order that the intensity of land use may be controlled to provide certain standards of light, air, and privacy to the occupants, to limit congestion on the streets, and to establish appropriate public services.

Origins of Zoning.—Rudimentary forms of zoning may be traced as far back as medieval regulations prohibiting certain activities from taking place within the town wall, and decrees concerning the location of industry were issued by Napoleon Bonaparte in 1810. For practical purposes, however, modern zoning principles were first developed by the Germans Reinhard Baumeister (1833–1917) and Franz Adickes (1846–1915) and generally applied in German cities during the last quarter of the 19th century.

Near the end of the same period, experimentation with zoning began in the United States. Boston limited the heights of all buildings in 1891, and similar restrictions in Washington, D.C., Baltimore, and Indianapolis soon followed. San Francisco enacted an ordinance restricting the location of laundries as early as 1883, and in the period 1909 to 1915 Los Angeles adopted a complex series of land-use measures. The first truly comprehensive and systematic zoning law, however, was the New York City ordinance of 1916. Prepared after more than three years of study by a distinguished commission of civic leaders, it went beyond any previous American or European model and set the basic pattern that has been followed ever since.

The rise of zoning in both Europe and the United States may be attributed in large part to the Industrial Revolution and the rapid growth of cities in the latter half of the 19th century. Prior to this time land and buildings had been controlled by the doctrine of common law nuisance—*sic utere tuo ut alienum non laedas* ("use your property so as not to injure another's"). However, this rough and individualized method of resolving conflicts (which runs back as far as the 13th century in England) appeared less and less adequate as the tempo and intensity of urban life increased.

At first cities reacted by legally prohibiting the worst overbuilding of land, for example, by setting height limits and by limiting the areas in which the most disagreeable industries, such as slaughterhouses and brickworks, could be carried on. However, a number of imaginative persons, particularly in New York City, shortly came to realize that by increasing the predictability of urban land uses and intensities, the zoning device could be a major factor in stabilizing property values and protecting real estate investment. Furthermore, from the city's point of view, a foreknowledge of future uses and building patterns would greatly increase efficiency in the planning, construction, and operation of public services of all types. Through the use of zoning, school, police, fire-fighting, rapid transit, sewer, water main, park, library, and other municipal facilities could be adjusted to the specific needs of the dis-

tract in which they were located. At the same time zoning would provide the working public with more light and air in buildings and lessen congestion in the streets by producing a more rational distribution of traffic-generating functions.

Arguments of this type gave zoning immediate popularity, and it spread very quickly across the United States. By 1926, only 10 years after the first comprehensive ordinance in New York, 30 million Americans were living in communities that had adopted zoning controls. As of 1960, some 2,000 ordinances were in effect, and zoning was being used by 95 percent of all towns and cities over 10,000, as well as by a large percentage of smaller municipal units.

Legal Basis.—Zoning ordinances are passed under the authority of the so-called "police power"—one of the great and fundamental attributes of government—commonly defined as the power of the state to act to protect the public health, safety, morals, and general welfare. Unlike the power of eminent domain, the police power may be used to impose restrictions on property without monetary compensation. In the United States the 5th and 14th amendments to the Constitution require, however, that in each exercise of the police power the public good obtained must "outweigh" the private inconvenience or loss incurred.

Since American law had traditionally permitted virtually unrestricted use of land, short of committing nuisance, zoning posed a serious constitutional issue. While most state courts supported the new ordinances, several found them unconstitutional. However, by using analogies from the law of nuisance and other arguments similar to those outlined in the preceding section, the advocates of zoning succeeded in obtaining a definitive approval from the United States Supreme Court in *Village of Euclid v. Ambler Realty Co.* (272 U.S. 365), decided in 1926.

Zoning and Planning.—There has often been confusion, even among judges and other public officials, as to the difference between the zoning map and a city master plan (or general plan, as it is often called). The master plan is a general and comprehensive guide to policy for community development for many years into the future. The zoning map and its accompanying text, by contrast, are detailed specific regulations controlling the use of land and the dimensions and location of buildings in the present.

Under sound planning principles, zoning should implement a previously prepared long-range master plan. However, because many municipalities adopted zoning ordinances before the introduction of the master plan concept into the practice of local government, much zoning in the United States is still not properly related to long-range community policies. This situation is now slowly being remedied as more and more municipalities and counties adopt master plans for their future development and revise outdated zoning ordinances in accordance therewith.

Special Exceptions and Variances.—The administration of zoning generally includes a zoning board of adjustment (or board of appeals), which has the quasi-judicial function of considering cases of individual hardship. "Special exceptions" are uses or buildings that the ordinance itself specifies may be permitted in a district after review by the board. "Variances" are changes in the actual requirements of the ordinance itself and are to be made by the board only in cases

where there are special conditions and where the strict application of the regulations would result in unnecessary hardship to the landowner. In both cases, the board must act only if it finds that the special exception or variance will not be contrary to the public interest. Some commentators on zoning matters feel that in many cities these procedures have been overused and that board decisions have been insufficiently related to firm policy expressed in a long-range plan.

Zoning Outside the United States.—While land-use controls in western Europe are often established in terms of so-called "zones" and regulate many of the same factors as in the United States, many European cities have prepared detailed development plans covering all or parts of their areas which subject the private developer to much more detailed regulation than in the United States. Moreover, since the end of World War II, legislation in some countries transferred land titles in bombed central areas to public ownership. This factor, plus the relatively large proportion of urban housing constructed by public authorities on the Continent, has tended to diminish the importance of zoning controls over private developments.

Prior to 1947, land-use controls in Britain were based on roughly the same principles as American zoning of the same period. However, since the Town and Country Planning Act adopted in that year, every development of land in the United Kingdom must be individually approved by the local planning authority for conformance with an official development plan, a stricter and more specific system than in the United States. Canadian zoning has followed United States practice, although sometimes with greater review at the provincial level than is common at the state level there.

In the historic past, many cities in Latin America, Asia, and Africa have been subjected to rigorous land-use and building controls, often still evident in the older quarters. In more recent times, however, particularly since the end of World War II, extreme population pressures and governmental attention to other matters have caused urban growth on these continents to be virtually unregulated. Individual cities have borrowed American zoning or European types of regulation, but often with only limited success.

United States Since World War II.—Since the end of World War II many major American cities have thoroughly revised their zoning regulations. The over-all trend in these revisions has been (1) to increase the specificity of control by increasing the number of district classifications, and (2) to increase the amount of administrative discretion by increasing the number of situations that require approval by the zoning board of adjustment, the planning commission, or other public body.

Recent revisions in zoning regulations have also introduced a number of new devices designed to give the private developer more freedom of action than under the rigid regulations of old ordinances. Among these are: (1) the floor-area ratio, a control governing the ratio of building floor area to total lot area, which permits more variety in the arrangement of building bulk; (2) the open-space ratio, which permits usable open space to be provided where most useful rather than in rigid yard requirements; (3) angle-of-light provisions, which assure light and air with less control on design; and (4) planned-unit pro-

visions, under which both dimensional and use requirements can be relaxed on review by designated public agencies and their approval of a well-considered design for the integrated development of a relatively large area. The last of these has become particularly important in zoning for urban renewal projects.

Reasonable and limited controls over historic parts of a city and the exterior architectural features of private buildings have been recognized in several states, including Wisconsin and Massachusetts. It is possible that this type of control will grow in the future, although the courts will probably be cautious because of the important constitutional issues involved.

In early ordinances, permitted uses were arranged in pyramidal fashion. At the top was the most-restricted residential district. Each successive category of residential, commercial, and industrial district permitted more and more uses, always including those of the preceding district, until the least-restricted industrial district had been reached. Later ordinances, of which the New York City Zoning Resolution of 1960 is a good example, have discarded this concept in favor of permitting "use groups" in each district, based on a careful study of what land uses are functionally related and naturally compatible, regardless of any abstract system of "higher" and "lower" categories. One simple example of this line of thinking has been the exclusion of residential uses from districts for heavy industry, since these functions are almost invariably incompatible.

Related to the use-group concept is the idea of zoning industrial uses according to how they actually perform. Under this system, which is applied in New York, Chicago, and a number of other cities, scientific instruments are used to measure the amount of smoke, dust, noise, odor, heat, glare, vibration, radiation, wastes, traffic, and other possibly objectionable factors that are or may be produced by a proposed industrial plant. Definite standards are then set for performance in each class of industrial district. A specific plant is permitted in a district if it meets the performance standards of that district, regardless of the type of industry that may be involved.

Early zoning legislation permitted uses and buildings established prior to the ordinance to be continued even though "nonconforming." Early zoning leaders expected that the passage of time would gradually eliminate such nonconformities. However, because of the durability of buildings and the economic advantage often accruing to owners from them and their nonconforming uses, natural elimination has been slow. Later ordinances in a number of larger American cities have set time limits on the life of nonconformities, ranging from a few years for uses with minor structures to two decades or more for substantial structures. These ordinances are designed to give the owner a reasonable time to amortize his investment while still assuring an ultimate change to a use or building conforming with the law.

Current Problems.—Most authorities agree that one of the most critical defects in American zoning practice has been the failure of many communities to prepare a long-range, comprehensive master plan and to integrate zoning and other land-use controls with it. The modern metropolitan area operates economically as one large community. Politically, however, it is generally divided into dozens or scores of independent municipal units, each having its own zoning power.

The result has often been local zoning patterns that have little relationship to the needs of the metropolitan area as a whole. Many students of this problem are concerned with creating procedures that will ensure some minimum level of metropolitan coordination in zoning while still permitting a maximum degree of local freedom. Another problem is the need for improved administrative procedures. With the increased scope of administrative review and the greater discretion of public officials in contemporary zoning practices, great care must be taken to assure that due process and fair treatment will be afforded to all persons affected.

In the United States, all power to engage in city planning and zoning flows from the state to local governmental units by means of enabling legislation. The enabling legislation of most states is still largely based on the Standard State Zoning Enabling Act and Standard City Planning Enabling Act prepared by the United States Department of Commerce in 1923 and 1927 respectively. This legislation is in need of complete revision, particularly with respect to the problems previously discussed.

Prior to the end of World War II, zoning could be characterized as the most important device available to implement city planning. In recent years, however, its importance has relatively decreased with the elaboration of subdivision regulations providing for review by a public body of the design and layout of new housing areas, and with the establishment of urban renewal procedures to improve the older portions of cities. Zoning does, however, represent a compromise between private rights and the public interest in urban development that has seemed especially congenial to American and Canadian social values. If continually revised to meet new needs and, above all, coordinated with long-range planning, it should continue to play an important role in urban development for many years to come.

ZOOGEOGRAPHY, zō-ə-jē-ōg'rə-fē, the science that deals with the distribution of animals over the surface of the earth. In addition to mapping the distribution of animals, it attempts to develop theories to account for the discovered facts. It thus involves a consideration of geological, geographical, and ecological factors and their influences upon animals and their movements.

Few kinds of animals are distributed worldwide; most are restricted to certain geographical areas. Thus each portion of the world has a characteristic fauna that differs from the others in

varying degrees. For example, the animal population of each of the islands of the West Indies differs only slightly from that of any neighboring island, while the animals of the opposite sides of the North American continent, though showing some like characteristics, differ in many respects. Some elements of the fauna of the western United States bear closer relationships to the animal population of Europe than to that of the eastern coast, and the whole of the North American fauna is much more similar to the fauna of Europe than to that of its southern neighbor, South America. The fauna of Australia is, in general, totally unlike that of any other continent, although certain species have relatives in North and South America. Most famous of these are the marsupial opossums of the New World.

So long as the belief in special creation was adhered to, these facts of distribution presented no problem, but with the development of the concept of evolution they challenged the attention and imagination of biologists. It soon became apparent that related species had common origins and must have dispersed from certain centers.

History.—Many early naturalists noted details of animal distribution and were struck by its peculiarities. Voyages such as Capt. James Cook's three-year circumnavigation of the globe (1768–1771) and Matthew Flinders' expedition to Australia (1801–1803) brought back to Europe ample evidence that different regions of the world possessed different faunas. Charles Darwin during the famous voyage of the *Beagle* (1831–1836) collected sufficient zoological materials and observations to enable him later to discuss the facts of animal distribution with authority. This voyage was the impetus for his later development of evolutionary theories that finally enabled scientists to explain some of the peculiar facts of animal distribution. One of the most important ideas in the development of the science of zoogeography was contributed by the 19th century geologist Charles Lyell, who pointed out that the present distribution of animals is conditioned by past changes involving major landmasses.

In 1858 Philip Lutley Sclater attempted to divide the world into zoogeographical regions, basing his work on studies of perching birds. Alfred Russel Wallace expanded Sclater's work in *The Geographical Distribution of Animals* (1876), basing his analysis on mammals. Wallace had worked as a field naturalist in the Malay Archipelago and South America and was impressed with the differences and similarities of these two distinct faunas. In his book, which is still one of the most important volumes on the subject, he divided the world into six zoogeographical regions, which he named Palaearctic, Nearctic, Ethiopian, Oriental, Australian, and Neotropical (see also section *Wallace's Line*). Since his time zoogeographers have been engaged in further studies of the regions, more careful analysis of the fauna, and the incorporation of new geological facts, evolutionary theories, and ecological principles in the interpretation of zoogeographical data.

Zoogeographical Regions.—A zoogeographical region is a geographical subdivision of the world that possesses a unique fauna. Based on Sclater's and Wallace's work, the world was divided into zoogeographic regions. This scheme was modified by Karl P. Schmidt in 1954. Schmidt divided the world into three realms: Arctogaeon, Neogaeon, and Notogaeon. The Arctogaeon consists of two

regions: the Holarctic, with the subregions Arctic, Nearctic, Caribbean, and Palearctic; and the Paleotropical, with the subregions Oriental, Ethiopian, and Malagasy. The Neogaeon consists of but a single region and subregion, the Neotropical. The Notogaeon is composed of two regions: the Australian, containing the Australian and Papuan subregions; and the Oceanian, which is formed of the New Zealandian, Oceanic, and Antarctic subregions.

Zoogeographical regions of the world, according to Karl P. Schmidt. Each, in general, has a distinct fauna.

These regions are not as distinctive as this listing would imply, for there are always groups of animals whose ranges extend through more than one region. In general, however, each of these areas has a distinct fauna with enough elements peculiar to it to warrant its listing as a zoogeographical region.

Most distinctive of all regions is the Australian which includes Australia and New Guinea. These areas have been isolated from other regions for so long that they have a distinctive fauna. Here are found the monotremes (egg-laying mammals) such as the duckbill; a large and varied assemblage of marsupials; and unusual birds like the emus, lyrebirds, honey eaters (honeyeaters), cockatoos, and the remarkable birds of paradise. The Australian lungfish, distinctive tortoises, and many unique invertebrates also belong to this region.

The Oceanian region includes New Zealand, Antarctica, and the oceanic islands of the Pacific. In New Zealand is found the curious lizardlike *Sphenodon*, only survivor of an ancient group, and the kiwi bird. The oceanic islands of this region are characterized more by the lack of many

groups of animals than by the presence of particular ones. There are, however, many distinctive shore fishes about the islands.

The Neotropical region, consisting of South America, has sloths, anteaters, armadillos, monkeys with prehensile tails, vampire bats, and marmosets. Among the unusual birds are the rheas, toucans, hoatzins, guans, and cassowaries. Many distinctive snakes are found, including boas, anacondas, and tropical pit vipers.

The Oriental subregion of the Paleotropical region includes southern India, southeast Asia, and the Malay Archipelago. It has many distinctive birds including pheasants, babbling thrushes, and barbets. Among the mammals are the Indian elephants, some lemurs, tigers, orangutans, gibbons, and some antelopes.

The Ethiopian subregion of the Paleotropical is formed of Africa south of the Sahara. It contains the aardvark, chimpanzee, gorilla, lion, and many kinds of antelopes. Among the birds are the ostrich and secretary bird. Close to Africa is the Malagasy subregion, consisting of the island of Madagascar and neighboring islands of the Indian Ocean. Madagascar has crayfishes that are lacking in Africa. It also has many different types of lemurs, including the aye-aye, and such unusual birds as the extinct gigantic *Aepyornis*, an ostrich-like bird that may have survived until historic times.

The Palearctic subregion of the Holarctic region consists of Europe, most of Asia, and Africa north of the Sahara. The Nearctic subregion consists of Canada, the United States, and a small portion of Mexico. These two subregions have many faunal elements in common, including distinctive deer, bears, wolves, rodents, and ungulates.

The Caribbean is a transitional subregion between the Holarctic and Neotropical regions. This area of Central America, Mexico, and the Caribbean islands possesses fauna derived from both the other regions as well as some distinctive features. The Arctic subregion is characterized by severe climatic conditions and various circum-polar mammals.

While each region has its unique faunal elements, it also shares other elements with different regions. The boundaries between them are at best hazy and ill defined. Nowhere is the tenuous nature of these boundaries more evident than in the various lines drawn to separate the Australian and Papuan subregions from the Oriental subregion.

See also separate articles on the various continents, countries, and islands mentioned.

Wallace's Line.—In 1860 Wallace reported that the western and eastern islands of the Malay Archipelago had faunas more distinct from each other than any other zoological divisions of the earth. He stated that "South America and Africa separated by the Atlantic, do not differ so widely as Asia and Australia." With the limited knowledge of the distribution of animals available during his time, Wallace considered the Strait of Lombok (between Bali and Lombok) as the dividing line between the Oriental and Australian faunas. In 1868 Thomas Henry Huxley called this "Wallace's line." It runs between Bali and Lombok, up through the Makassar Strait between Celebes and Borneo, and then between Mindanao in the Philippines and the Sangi Islands.

After a period of enthusiastic acceptance of this faunal boundary, zoogeographers began to

doubt its validity. Many believed the line to be imaginary; most believed that such a sharp boundary could not be drawn between any two faunal regions. As knowledge increased, Wallace's line was no longer accepted as the boundary between the two regions. That there is a vast difference between the faunas of Bali and Lombok, which are separated by only about 20 miles, or between the rich fauna of Borneo and the relatively poor faunas of the Celebes and the Philippines, cannot be denied. This difference is due, however, to the existence of an impoverished young fauna in one area and an older, richer fauna in the other. Its background can be understood only by a consideration of geological events. Much of the area east of Wallace's line underwent great disturbance in the Tertiary period, and some of the islands did not emerge until the Pleistocene. Thus the western islands represent essentially a continental fauna and the eastern islands an insular one.

Further studies resulted in the establishment (1904) of another line, known as Weber's line, drawn much farther east and based largely on soundings and oceanographic data. In many respects it fits the known zoogeographical picture, with the fauna to the west predominately Oriental and to the east Australian. Many zoogeographers have refused to accept Weber's line and prefer a broad belt as the separation zone. One problem is that if a line is drawn along which there are 50 percent Oriental and 50 percent Australian elements for one group of animals, it may not be the same for another group. This is due in part to the difference in motility of different kinds of animals. The highly motile birds can move more readily to a new landmass than the slowly moving reptiles or many invertebrates. As further evidence of these differences, the flora of New Guinea is largely Oriental, its fauna strictly Australian.

Dispersal of Animals.—With the recognition of the principles of evolution, it became evident that various types of animals arose in different areas and spread out from these centers. Because of geological history and geographical location, certain areas have been especially important as centers of origin. In North America, the highlands of Mexico, the Ozark uplift, and the Appalachian Mountains are such centers.

The difference in the ability of animals to move from one area to another makes some better indicators of zoogeographical affinities than others. Many of the smaller freshwater animals such as the protozoans, sponges, rotifers, and some crustaceans have resistant stages or eggs that may be carried from one region to another with ease. They may be blown by the wind, carried on the feet of birds, or transported in many other ways. As a result, many of these species are cosmopolitan in distribution and of little value in zoogeographical studies. At the other extreme are forms such as freshwater fish or earthworms that are quite restricted in their ranges. These cannot stand immersion in salt water, and hence the presence of similar species in two areas is ordinarily indicative of land connections.

Animals with wings such as the birds and some insects are often blown long distances by the wind and dispersed in that way. Reports are frequent of American birds reaching the coasts of Britain and France during heavy storms. Another common method of dispersal is the floating log. Many species of arthropods may cling to such logs as they float out to sea and so are carried long distances.

Speed of dispersal also varies greatly among different animals. Thus the flying birds, bats, and winged insects may spread quickly into a new area while slowly moving terrestrial animals may take years to occupy a new habitat. Even among the latter there are differences. One can scarcely compare the speed of a large mammal or reptile to the slower movements of a salamander or an earthworm.

At any rate, all animals tend to multiply beyond the capacity of their immediate surroundings to support them. As a result, they spread out from these original centers until stopped by some barrier.

Barriers.—Barriers to the continued spread of animals are of many different types. Most obvious are definite physical barriers such as oceans, deserts, mountains, or large rivers. Long stretches of ocean, while not a barrier to many birds, may prove absolutely impassable to many mammals, amphibians, freshwater fish, earthworms, and other invertebrates. A desert may stop the spread of many animals dependent upon sufficient moisture, while mountains may be an effective barrier to other forms. Large rivers, while no barrier to large mammals, may be effective barriers to some small species. Climate likewise may limit the distribution of some forms. Most species are physiologically adjusted to certain temperature and humidity ranges, and they can only spread a certain distance until they are stopped by climate extremes outside their range of tolerance. Thus many tropical insects may not be able to move outside the tropical zone or into the cold areas of high mountains because of climatic limitations.

More difficult to measure but nevertheless important are factors that may be termed ecological pressures. If an animal moves into an area already occupied by a similar species having nearly identical food habits and living in a similar habitat, the new animal will probably not be able to survive and occupy the area. The competitive species may prove an effective barrier.

Obstacles that may act as barriers to one kind of animal may prove to be corridors for the migration of another; thus high mountains, while limiting the spread of a tropical form, may be a pathway for an animal living in a cool climate. Many of these problems of dispersal and the effect of barriers may be studied effectively with island faunas.

See also **ECOLOGY**.

Island Faunas.—Islands have always been a favorite topic for students of evolution and animal distribution. In general an island is one of two types: continental or oceanic. Continental islands are located near larger continental masses of which they were once a part. They usually have a rich, balanced fauna resembling the neighboring landmass. Frequently they have many species in common with the nearby continent, and the unique species are usually closely related. Examples of continental islands are Great Britain and the small islands off the California coast.

Oceanic islands, on the other hand, arise independently of continents. The volcanic and coral islands of Polynesia are examples of this type. Their faunas are derived from forms that arrived accidentally, found conditions suitable, and then became established. Thus we find that many of these islands lack a mammal fauna or have only bats, and usually have a number of species of oceanic birds and only a limited assortment of insects. The fauna is commonly poor and distinctly

unbalanced as compared to continents. The island of St. Helena, about 1,200 miles from Africa and even farther from South America, originally possessed no native vertebrate fauna but had 129 species of beetles, all but one unique.

Because of their isolation, many islands lack large predators. This has enabled unique species to develop that could not have survived on a continent. These include such forms as the dodo of Mauritius in the Indian Ocean and the solitaire of nearby Rodrigues, both large, flightless, clumsy birds, now extinct.

Historical Factors.—Many facts of the present-day distribution of animals are explicable only by reference to past geological history. For example, the zoogeographer wants to know why tapirs are found in both tropical America and the Malayan region, marsupials in both America and the Australian region, and camels in Asia and the Andes. Obviously such discontinuous distribution cannot be explained satisfactorily by looking at the present-day formation of continents and oceans. Instead, zoogeographers must turn to a study of fossil remains and geological history.

Since discovered fossils and much crucial geological information are still fragmentary, different interpretations have been given to the available facts. One large group of zoogeographers believes that through most of that part of geological history when life has been present, the continents and oceans have been essentially the same as they are today. Peculiar relationships and distribution are explained by various dispersal methods, such as wind. This school of thought is willing to admit, however, that at times in the past there were various land bridges for dispersal, including connections from present-day Alaska to Asia over what is now the Bering Strait, connections in the north between North America and Europe, and a land link between Asia and Australia. Certainly it is known that various parts of land are often submerged, rise again, and then sink. One example is the Central American land bridge, certain portions of which, in past ages, sank repeatedly below the sea to rise again later. The opening and closing of this bridge had its influence on the migrations of animals between the two American continents.

Another group of zoogeographers has postulated more extensive and numerous land bridges to account for the distribution patterns. Still another group believes that at one time, about the Late Paleozoic era, the continents were all united and that this single landmass fragmented into the present-day continents, which then drifted to their present positions; this is known as the "continental drift" theory. While proponents of these various theories support them vigorously, more geological and zoogeographical investigation will have to be made before definite conclusions can be reached.

See also **LAND BRIDGES ACROSS THE OCEANS**; **PALEOGEOGRAPHY**.

Zoogeography of the Sea.—While most zoogeographical principles have been based on terrestrial and freshwater studies, the sea too has been investigated. In many ways, the knowledge of ocean animals is more limited than that of terrestrial ones. This, together with some unique problems of the sea, has tended to make it more difficult to divide the ocean into zoogeographical regions. For one thing, unlike the land, the oceans are continuous throughout the world. Thus some larger marine animals such as whales may range

over the entire world. Also many invertebrates that are sessile or slow moving as adults may have pelagic larvae that are carried by waves and currents for many miles; these include such animals as worms, echinoderms, sponges, and mollusks. As a result, some species are widely distributed and may be found in many regions of the world where ecological conditions are favorable. Thus the presence or absence in a given area of any one animal may be more dependent on local ecological factors than on historical zoogeography.

In spite of these difficulties, zoogeographical regions are found to be recognizable in the ocean. In fact, studies made on marine faunas have at times helped to shed light on terrestrial problems. Certain tropical shore fishes on the Atlantic side of Central America closely resemble others on the Pacific side. This resemblance can be accounted for only on the basis of breaks in the Central American corridor in previous geological periods.

See also FISH—*Distribution and Habitat*; MARINE BIOLOGY.

Influence of Man. As humans have spread over the earth, they have transported many animals with them. Some, such as pigs, dogs, and goats, have been carried deliberately; others, such as rats, mice, cockroaches, bedbugs, and fleas, have been brought along unknowingly. Even primitive man played a small part in transporting animals. When the first white men visited Australia, they found a dog, the dingo, whose ancestors had been brought in by the aborigines, and pigs were transported to the Solomon and New Hebrides islands by the natives.

Sometimes human introduction of animals has so upset the balance that natural forms have

been destroyed. This is especially apparent on islands, where the unwitting introduction of rats has at times completely killed off the native birds by destroying their eggs and young. Goats left on islands by mariners have multiplied and destroyed the vegetation, so that the native fauna dependent on the vegetation has disappeared.

With the advent of rapid transportation and extensive commerce in modern times, the introduction of animals to new localities has become more frequent. Many insects, birds, rodents, and other animals have been introduced into new lands; frequently these new forms have caused disturbance of the native biota.

ZOOLOGICAL GARDENS, zō-ə-lōj'ī-kəl gār'dənz, gardens or parks where wild animals are exhibited and studied. The relationship between man and animals that finds expression in the modern zoological garden (or zoological park, as it is more commonly called in the United States) dates approximately from the 18th century. Its essence is an interest in wild animals not only as

The Bronx Zoo, in New York City, pioneered in providing natural surroundings and greater liberty for its animals.

SCHWIMMER/BRUCE COLEMAN

K. W. FINK/BRUCE COLEMAN

The San Diego Zoo, one of the largest zoos in the world, is a model of how animals should be presented to the public.

captive curiosities, but for their own sakes: for the role they play in the economy of nature; for the study of comparative anatomy and behavior; and for aesthetic and cultural reasons.

History and Extent. The earliest approach to a modern zoo was the Park of Intelligence created by a Chinese ruler about 1150 B.C. in the province of Honan and maintained for several hundred years thereafter; mammals, birds, turtles, and fish were kept under natural conditions. The ancient Egyptians, Assyrians, and Babylonians also kept wild animals, primarily to enhance the glory of their rulers; and large numbers of animals were imported by the Romans for combats between man and beast, or beast and beast, in the arena. In the Middle Ages, lions, monkeys, peacocks, and similar exotic fauna were exchanged as presents between the rulers of states. These collections, furnishing a ready supply of animals for hunting or kept for reasons of prestige, led insensibly to the establishment of royal or public menageries on a more or less permanent basis in many parts of Europe. As the scientific spirit of inquiry developed in the 18th and early 19th centuries, the menageries lay ready to hand for the work of such celebrated naturalists as the comte de Buffon, Georges Cuvier, and the chevalier de Lamarck.

The great early collections of wild animals were connected for the most part with courts or cities in the Old World, but the New World had its counterpart under the Aztec ruler Montezuma, who built enormous installations for mammals, birds, reptiles, and fishes and employed specialists to catch and breed animals for his collection and to look after their health. The collection was destroyed by Hernán Cortés in 1521.

The United States was comparatively late in showing an interest in animals, other than as a source of food or sport, or to cater to idle curiosities in the exhibitions of traveling showmen. The

first zoological garden in the United States was opened in Philadelphia in 1859. The country has since made up for its slow start and now has more than twice as many recognized zoos as any country in the world. According to the *International Zoo Yearbook*, published by the Zoological Society of London, there are more than 400 zoos in the world; countries noted for their numerous zoos include the United States, East and West Germany, Japan, Britain, Soviet Union, Czechoslovakia, Poland, India, and the republic of Ireland.

Besides the zoos that enjoy municipal or county support and are tax exempt, there are in the United States innumerable "roadside zoos," game farms, private menageries, and circus collections of wild animals. "Going to the zoo" has become a major American form of recreation. Reported world attendance at zoological gardens is about 200 million, of which United States zoos account for 50 million.

Methods of Presentation. Concepts of how animals should be presented to the public in a zoological garden are constantly changing in the direction of more natural surroundings and greater liberty for the animals, and special exhibits or situations are created to demonstrate the animals' normal way of life. The trend away from restraining bars began in Germany at the end of the 19th century, and the moated or barless enclosure is now commonplace. It has been found that even free-flying birds can be controlled within exhibition buildings, without restraining wire mesh or glass. Typical examples are at the St. Louis and Philadelphia zoos, where the exhibits are heavily planted, providing concealment and perches. The public space beyond is comparatively bare of these so that the birds tend to stay in the habitat exhibit.

Elsewhere, "walk through" exhibits of birds introduce the visitor into the birds' habitat, as in

ZOOLOGICAL SOCIETY OF SAN DIEGO

An animal health technician uses a blowgun to vaccinate a Przhevalsky's horse against tetanus.

the San Diego zoo, where visitors may stroll through a screened tropical rain forest exhibit containing hundreds of birds. Since the screened area is comparatively large—170 feet long, 80 feet wide, and 90 feet high—and contains many large trees, the birds are essentially at liberty to lead lives as in nature. The endeavor in such installations is to display the animal against its own background insofar as possible, so that the visitor carries away an understanding of its way of life rather than a mere impression of form or color.

Mammals also lend themselves to ingenious and modern methods of display. An example is the reversal of the day-night cycle in nocturnal mammals accomplished in the New York Zoological Park. Small mammals seldom seen by zoo visitors except as curled-up balls of fur have been induced to be active by day and to sleep at night by bathing them in red fluorescent light from 11 A.M. to 11 P.M. and in white light for the remainder of the 24-hour period. Because of the structure of the eyes of night-active animals, the red light is "invisible" light to them, and they readily wake up and begin feeding and prowling when the red light comes on, and just as promptly go to sleep under white light. Flying squirrels, night monkeys, pottos, galagos, kinkajous, and similar nocturnal mammals respond quickly to the red-light routine, becoming adjusted usually within a week.

Role in Conservation. The major zoological gardens of the world are playing an increasingly important part in the conservation of wild animals, in the preservation of rare species, and in

the protection of animal health. Père David's deer, Przhevalsky's (Prjevalsky's) horse, the wisent, and the nene or Hawaiian goose, to name but a few, would be extinct today if it were not for the breeding and protection encouraged or otherwise fostered by zoos. On the broad front of wildlife conservation, the New York Zoological Society, which operates the New York Zoological Park, has taken leadership in America in the conservation of threatened species, particularly in Africa, the American West, and Alaska. The need for wildlife protection in Africa became acute with the withdrawal of the colonial powers, and through a special fund the New York Zoological Society has made ecological surveys, trained Africans in conservation, drilled wells in drought-stricken areas, and aided in the enforcement of anti-poaching laws.

Through cooperative efforts by zoological parks, increasing numbers of rare animals are being bred in the United States. This has been accomplished by the practice of "pairing up" single animals in different zoos, the resulting offspring being divided among the participants and other interested zoos.

Protection of Health. Major zoological parks in the United States maintain full-time veterinarians to safeguard the health of the collections, and in the larger cities the zoo veterinarian usually has close liaison with pathologists and technicians in the local hospitals. These specialists may work directly with the veterinarians when a difficult or especially interesting case arises, and in turn the zoo's collection is a ready source of animal tissue for research studies by zoologists,

anatomists and pathologists. The usefulness of many zoo animals does not end with their death; the blood, heart, lungs, liver, brain, and other organs may be distributed to specialists whose requirements are on file with the veterinarian.

Zoo experimentation has been important in the development of various types of guns and pistols that fire syringe cartridges loaded with drugs, anesthetics, or tranquilizers, making it possible to immobilize and treat many animals that previously could not be restrained or could be held for treatment only after violent and dangerous struggles. These syringe-firing devices have also been used with success in the field, particularly in game-tagging studies in the American West and in Africa.

Acquisition. There are six ways by which zoological gardens acquire their animals: by birth in the collection; purchase; gift; exchange with other zoos; direct collecting on expeditions; and by the voluntary action of animals that fly or wander into the zoo grounds. The world-wide network of airways has made access to the homes of exotic fauna so easy and transportation back to the zoo so fast the zoological gardens are fast approaching the end of the more spectacular "never before exhibited" animals. It has been estimated that there are about 3,200 kinds of mammals in the world today, 8,600 birds, and 6,000 kinds of reptiles and amphibians. While very few zoological gardens have ever exhibited more than 1,000 kinds of animals in a given year, over the years almost all of the known, really spectacular animals have been exhibited in one zoo or another. The future may not see many

"new" animals in zoological gardens, but it will certainly see them exhibited more naturally and more meaningfully.

WILLIAM BRIDGES,
Curator of Publications, New York Zoological Society.

ZOOLOGY, zō-ōl'-ō-jē, the science that deals with animals. In the present article, the subject is discussed under the following main headings:

- | | |
|-----------------|-------------------------|
| 1. Subdivisions | 3. Groups of Animals |
| 2. History | 4. Evolutionary Zoology |
| | 5. Bibliography |

1. Subdivisions

Animals and groups of animals have many properties; hence zoology has a number of subdivisions. These subdivisions, in turn, do not find their limits within zoology but are part of the broader subject of biology, since many of the properties of animals are possessed in common with other living things. Genetics, for example, embodies concepts that apply alike to microorganisms, plants, and animals. Yet a study of the genetics of bacteria is, properly speaking, microbiology; a study of the genetics of corn is botany; and a study of the genetics of the fruit fly or of man is zoology.

The aim of zoology is to understand the lives of animals. By animal life is meant the sum total of all of the properties of animals and animal populations. For this reason the subdivisions of zoology overlap one another and serve, only in the roughest way, to classify the activities of zoologists. The physiologist, for instance, may study the function of the kidney, but in doing so he cannot ignore its structure, which is the proper sphere of study for the anatomist. There is, however, general agreement about the major subdivisions. *Morphology* or *anatomy* deals with the form and structure of animals. Studies of this kind may be carried out at a gross or at a microscopic level. In the latter case the investigation may be of groups of cells and be known as *histology* or may concern the structure of the cell itself, in which event it is called *cytology*. *Physiology* is concerned with function and behavior, with the mechanism of whatever processes can be recognized in animals. A physiological analysis often proceeds to a chemical or physical level. Investigations of behavior may sometimes properly be termed *psychology*. *Embryology* is the science of the development of individuals and may be anatomical, physiological, biochemical, or genetic. *Genetics* is the study of heredity and deals with the nature of hereditary determinants, their synthesis, mutability, and mode of action, and the way in which characters are passed from individual to individual and, in populations, from generation to generation. *Taxonomy* or *systematics* deals with the classification of animals, their nomenclature, and their family relationships. The study of fossil forms from all points of view is *paleontology*. *Ecology* takes up the relationships existing among animals and between animals and other organisms and their environment. So defined it includes *parasitology*, or the study of animals that live at the expense of other organisms.

During the 19th century the whole of zoology was unified by the theory of evolution. This conception allowed an understanding of how the various kinds of animals of present times,

with their structures, functions, and interrelationships, may have come about, and offered an explanation of the patterns of similarity. Since the emergence of evolutionary theory, a main objective of zoologists has been not only to study how animals maintain themselves, reproduce, and develop, but to analyze the historical or evolutionary background of such existing systems. Initially studies on evolution were descriptive and used the observational approach. Especially when such studies involved living animals in their usual habitats, they were considered a part of "natural history." Although natural historical investigations continue and have scientific worth and an aesthetic value of their own, the beginning of the 20th century saw an upsurge of a special type of experimental investigation. Such investigations often utilize chemical, physical, and mathematical methods and are usually referred to under the headings of *biochemistry*, *biophysics*, and *biometrics*. These subjects also overlap among themselves and with those already mentioned; there is a biochemistry of development just as there is a biochemistry of muscle function.

The subject matter of zoology is also divisible in terms of the animals being studied. For example, *vertebrate zoology* is the study of animals with backbones; *invertebrate zoology*, the study of the remainder of the animal kingdom; *ornithology*, the study of birds; *protozoology*, the study of protozoa. It is sometimes hard to decide whether a protozoan belongs to the animal kingdom, the difficulty residing in the fact that plants and animals were first defined at a time when microorganisms were unknown. Perhaps it is preferable to relegate the protozoa and the protophyta to a separate kingdom, Protista (or Protoctista). Both botanists and zoologists, however, consider these organisms their legitimate subject material.

2. History

Antiquity and Early Modern Period.—The first attempt at a comprehensive classification of animals and their properties was made by Aristotle (384–322 B.C.). Classical antiquity saw many other efforts, the major one probably being the voluminous work on natural history by Pliny the Elder (23–79 A.D.). Galen (129/130–199/200 A.D.) was another early authority of great influence. He dissected animals for his works on human anatomy, which were in standard use in medicine throughout the Middle Ages. During the Renaissance, Konrad Gesner (1516–1565) compiled an encyclopedic natural history that was characterized by an attitude of scientific skepticism. Leonardo da Vinci (1452–1519) and Andreas Vesalius (1514–1564), imbued with the new spirit of investigation, accumulated through dissection a knowledge of human anatomy far more exact than that which had hitherto existed. The ideas of Francis Bacon (1561–1626) spread in the 17th century, and an increasing emphasis was placed on direct observation and experiment.

One of the most successful users of the ex-

perimental method was William Harvey (1578-1657), who demonstrated the circulation of the blood and the function of the heart, arteries, and veins. The invention of the microscope introduced a series of investigations into the fine structure of animals especially by such men as Anton van Leeuwenhoek (1632-1723), Jan Swammerdam (1637-1680), and Marcello Malpighi (1628-1694), who discovered capillary circulation. The researches of Caspar Friedrich Wolff (1733-1794) in embryology established the fact that the organs of the embryo develop from the relatively indifferent material of the egg and are not preformed in an infinite series. Lazzaro Spallanzani (1729-1799) experimented on spontaneous generation and correctly recognized the basic continuity of life.

Taxonomy and Morphology.—A real advance in the classification of animals was made by John Ray (1627-1705), who was consistent in employing structural similarity as a criterion. His work was brought to a culmination by Carl Linnaeus (1707-1778), who introduced the binomial system of nomenclature (genus and species, as in *Homo sapiens*) and whose *Systema naturae* (1735) marks the beginning of the modern system of classification. Comparative anatomy and natural history developed rapidly during the 18th century under the impetus of such scholars as the comte de Buffon (1707-1788) and Johann Wolfgang von Goethe (1749-1832). The fact of evolution became clear to Erasmus Darwin (1731-1802), the chevalier de Lamarck (1744-1829), and others who believed, but could not experimentally demonstrate, that evolution occurred by the inheritance of characters acquired through use or disuse. The great French tradition was carried forward by Georges Cuvier (1769-1832), who extended his morphological studies to fossil forms. Investigations that were to help make Germany the center of zoological research in the 19th century were carried out especially by Karl Ernst von Baer (1792-1876) in comparative embryology and by Karl Gegenbaur (1826-1903) in comparative anatomy.

Evolution and Experimental Research.—The seeds of evolutionary theory were nourished by the explorations and collections of great naturalists such as Alexander von Humboldt (1769-1859) and by demonstration of the principles of geological succession by Charles Lyell (1797-1875). In the intellectual climate thus created, Alfred R. Wallace (1823-1913) and Charles Darwin (1809-1882), themselves competent and traveled naturalists, simultaneously in 1858 proposed theories of evolution based on natural selection. The impact on zoology and other fields of learning was immediate and explosive. General acceptance of the new interpretation was not equally rapid; for example, Richard Owen (1804-1892) in England and Louis Agassiz (1807-1873) in America, whose researches in comparative anatomy and paleontology were later to be of great value to evolutionary theory, rejected it. Nonetheless, an intensive period of research into the course of evolution ensued; the great popularizers of this knowledge were Herbert Spencer (1820-1903), Ernst Haeckel (1834-1919), and Thomas H. Huxley (1825-1895). The new spirit spread, and vigorous programs in paleontology were initiated in Europe and in the rich collecting areas of western America.

Although the evolutionists of this period were satisfied to explain things in terms of their historical origin, a new group of workers demanded answers in terms of mechanism. For example, in embryology, the comparative approach was amplified by an experimental one, especially through the efforts of Wilhelm His (1831-1904), Wilhelm Roux (1850-1924), and Hans Spemann (1869-1941). This experimental philosophy was vigorously applied to other fields of zoology throughout the 19th century. Friedrich Wöhler (1800-1882) in synthesizing urea showed that organic compounds, previously found only in association with living organisms, could be made in the laboratory; thus they were stripped of their aura of mystery. Johannes Müller (1801-1858), Hermann von Helmholtz (1821-1894), and Claude Bernard (1813-1878), conducted their physiological researches in a similar spirit.

Cytology and Genetics.—The role of the cell as a unit of structure was recognized as early as 1838 by Matthias Schleiden (1804-1881) and Theodor Schwann (1810-1882), and detailed investigations into cell division, including the behavior of chromosomes, were conducted by Karl von Nägeli (1817-1891) and Eduard Strasburger (1844-1912). During this era Rudolf Virchow (1821-1902) established the science of cellular pathology. The role of the nucleus in fertilization, cell division, and sex determination progressively came to be understood through the efforts of Oskar Hertwig (1849-1922) and his brother Richard von Hertwig (1850-1937), Walther Flemming (1843-1905), Otto Bütschli (1848-1920), Edouard van Beneden (1846-1910), Theodor Boveri (1862-1915), and Edmund B. Wilson (1856-1939). August Weismann (1834-1914) combined this new cytological knowledge into a comprehensive theory of heredity and evolution based upon natural selection and emphasized the continuity and independence of the germ plasm. Other important students of heredity and evolution included Francis Galton (1822-1911), who introduced statistical methods to the field, and Wilhelm Ludwig Johannsen (1857-1927), who clearly distinguished the hereditary composition (genotype) from the observable characters (phenotype) of an individual. A major advance in the study of inheritance came with the rediscovery in 1900 of the laws first recognized by Gregor Mendel (1822-1884) about 1865. These laws were further developed by Hugo De Vries (1848-1935), William Bateson (1861-1926), and Thomas Hunt Morgan (1866-1945) and his school, who, among other things, were able to show that the bulk of the hereditary units were aggregated in the chromosomes. The generalizations of Mendelian genetics offer the broadest opportunities for the accurate prediction of biological events. In this way they approach the laws of the more highly developed physical sciences.

Although the names of individuals have been singled out for mention, it should be understood that zoology, like every other branch of knowledge, has grown through the concerted efforts of multitudes of unmentioned investigators, some of whose contributions may have been as great as those of the zoologists named.

Present Orientation.—In general, it can be stated that until the 20th century a strong emphasis was placed on differences in structure and

function. Hence botany, zoology, microbiology, and subdivisions within these fields followed relatively separate developments. With the progressive accumulation of knowledge, especially in cytology, genetics, and biochemistry, the 20th century has seen a reversal of this emphasis. The fundamental similarity of all living things is now apparent, and information secured about animals is often directly transferable to plants and vice versa. Of course there are differences, but in order to be alive, to maintain life, and to reproduce, certain common features are required.

See also biographies of individual scientists.

3. Groups of Animals

Animals inhabit almost all parts of the earth from the equator to the poles, from the depths of the oceans to high mountain summits. They have invaded the soil, the water, and the air and have even become adapted to live within other organisms. Accordingly their diversification of form and function is great. About 800,000 different species of animals have been recognized, and it is estimated that the total number might exceed 1,500,000.

Classification.—A species is a group of similar animals which ordinarily interbreed with one another and not with others. Similar species are grouped in a genus and similar genera in a family. Higher categories include, in turn, orders, classes, and, finally, phyla, which are the major subdivisions of a kingdom. There is not always universal accord among zoologists as to whether a group of animals should be considered in one or more species, and similar difficulties are encountered with higher categories; this is a consequence of the fact that the array of animal life reflects the fundamental relationship of forms that have evolved with modification from common ancestors. Nevertheless, a generally satisfactory listing of the major groups of animals is as follows:

Kingdom: Animalia	
Phylum: Protozoa	Echiuroidea
Mesozoa	Annelida
Porifera	Arthropoda
Coelenterata	Mollusca
Ctenophora	Entoprocta
Platyhelminthes	Bryozoa
Nemertinea	Phoronidea
Nematoda	Brachiopoda
Rotifera	Chaetognatha
Sipunculoidea	Echinodermata
Priapulida	Chordata

See also ANIMAL; ANIMAL CLASSIFICATION.

Protozoa.—The Protozoa are distinguished by the fact that their bodies are unicellular. Nevertheless, they can be exceedingly complex in structure. This is not surprising when one reflects that their microscopic bodies are adapted to carry out all of life's functions. Their organs, such as the locomotor apparatus, food canal, and nervous and excretory systems, are differentiations of their protoplasm and not, as in other animals, composed of cells, each with its own nucleus. There is a nucleus in the protozoan body (sometimes there are several), and its experimental removal and transplantation have demonstrated that it is required for the continued normal function of the protoplasm. In asexual reproduction the nucleus divides as does that of the cells of metazoa (animals whose bodies are composed of cells). Some protozoa undergo sexual reproduction, and when they do so, nuclear changes take place that are not unlike those occurring in the formation of sperm

and eggs and in fertilization of metazoa. As a consequence, inheritance in protozoa is fundamentally like that in metazoa, for in both cases the majority of the hereditary factors or genes are on the chromosomes of the nucleus. Protozoa have been shown, in some cases, to require the same types of food as man, that is, amino acids, vitamins, and minerals. In fact, the chemistry by which they secure building material and energy from proteins, carbohydrates, and fats is not fundamentally different from that of other organisms.

Undoubtedly one of the earliest states of life on earth consisted of animals built on the protozoan plan. From the Proterozoic era (perhaps a billion years ago) onward the protozoa have retained this basic plan while modifying it in some respects. In this group there are forms that possess chlorophyll and manufacture their own food from carbon dioxide and water with the energy of sunlight. But even this does not make us sure that they are plants, for under certain conditions they can be made to lose their chlorophyll, and provided they are given certain foods, they move about and reproduce like other protozoa. Nevertheless, it seems certain that the plants in evolution arose from green flagellates. Some protozoa live in aggregations, suggesting that from similar aggregates the many-celled plants and animals arose long ago. Others are shelled forms, such as the foraminifera and radiolaria, especially prolific in the seas, where their skeletons fall in a constant rain to the ocean floor. In the past similar deposits have been transformed into stone, and since the populations of shelled protozoa varied with time, the microscopic analysis of shale containing protozoan skeletons is a guide to geologists in their search for oil. The largest of these shelled protozoa is a fossil form that was sometimes more than an inch in diameter. Many protozoa have complex life cycles and are parasitic in other organisms. *Plasmodium*, which causes human malaria, passes part of its life in the body of a mosquito.

See also PROTOZOA.

Mesozoa and Porifera.—The bodies of unicellular organisms are nearly always small while the metazoa, or many-celled animals, may grow large. Whenever size is great, the problem of transport of food, waste products, and oxygen in and out of the depths of the body becomes increasingly difficult. This problem arises because as size increases, there is a proportionately greater increase of volume than of surface. The metazoa solve this problem either by forming thin-branched colonies, or by developing enlarged body cavities, or systems of circulatory vessels. They must also, in growing large, develop some type of skeletal support.

To the phylum Mesozoa belong some microscopic parasitic animals that are interesting phylogenetically because of the primitive aggregation of their cells into a solid body consisting of two layers.

The Porifera or sponges, like the Mesozoa, possess bodies with two layers of cells, but some relatively unorganized cells are located in between. This organization is in fact so plastic that when the cells of a sponge are separated by being squeezed through fine cloth, they are able to aggregate to form a new sponge. The body of a sponge is riddled with numerous canals lined by flagellated cells which create a current

of water and ingest food particles thus carried in. As sponges increase in size, many of them form spicules in the middle layer that afford a type of skeletal support. The siliceous spicules of some fossil sponges form a rock known as flint. See also SPONGES.

Coelenterata and Ctenophora.—The Coelenterata, or jellyfish, anemones, and corals, have a better-developed middle layer. They have a mouth but no anus, waste material being ejected through the same opening it entered as food. Some forms increase in size by branching, the result being a colony of zooids connected by a series of stems through which the gut passes. Such polyps or hydroids may have an alternation of generations whereby a jellyfish stage is budded off. These free-swimming medusae form eggs and sperm, and the fertilized eggs develop once again into hydroids. Some jellyfish have lost the hydroid generation, and their fertilized eggs develop directly into medusae again, while others have only the hydroid stage. Food and oxygen are brought into the thick bodies of jellyfish by canals. Some of these forms possess special stinging cells that are dangerous even for man. Although sea anemones may also become large, their bodies are relatively thin walled, and the gut is divided by septa. The corals are mostly colonial sea anemones that secrete different sorts of skeletons. They are exclusively marine and sometimes form massive coral reefs and coral atolls, as in the Pacific Ocean. Much limestone is composed of fossil coral. All of the Coelenterata have bodies that are symmetrical around a central axis. This is called radial symmetry and is also characteristic of the phylum Ctenophora, or comb jellies. The latter forms are constructed somewhat like the Coelenterata but have eight rows of paddlelike plates by means of which they swim. Many of them can carry out chemical reactions that produce light and so are the source of bioluminescence when the sea is disturbed on a summer night. See also COELENTERATA; CORAL AND CORAL REEFS; JELLYFISH; SEA ANEMONE.

Platyhelminthes and Other Worm Phyla.—The remaining animals are bilaterally symmetrical or have evolved from such forms. Bilateral symmetry means that the halves of the body are essentially mirror images of one another. Most primitive is the phylum Platyhelminthes, which includes free-living flatworms and the parasitic flukes and tapeworms. When a gut is present, it is a blind sac opening only through the mouth. The middle layer or mesoderm is well developed, and there is a system of excretory canals whose fluid contents are agitated by cells possessing a motile bundle of fibers. There is also a well-developed nervous system with some centralization in a ganglion at the head. The Platyhelminthes are usually hermaphroditic. The free-living forms, like *Planaria*, have considerable regenerative power; whole animals can be re-formed from small parts. They can also shrink to a small fraction of their original size when starved. The parasitic forms ordinarily have complex life cycles that sometimes involve several intermediate hosts. They are of great medical importance, especially in tropical regions. The Nemertinea, or nemertean worms, are in some respects like the Platyhelminthes, but they have an anus, an eversible proboscis, and a rudimentary circulatory system. See also PLATYHELMINTHES.

The Nematoda consist of the free-living and parasitic roundworms, and the Rotifera comprise the rotifers or "wheel animalcules." The nematodes are of great medical importance, causing such diseases as hookworm and elephantiasis. The Sipunculoidea, Priapulida, and Echiuroidea are worms related to the segmented Annelida. One of the echiuroids shows an unusually plastic mode of sex determination. The larva, if attracted to and settled on a female, develops into a male. If, however, it settles free on the ocean bottom, it differentiates into a female. The Annelida, a group that includes the earthworm and the leech, have contractile blood vessels and well-formed body cavities from which the excretory organs lead as tubes to the outside. Most of the structures of the body, such as the appendages, muscles, excretory organs, ganglia on the nerve cord and lateral nerves, and blood vessels, occur in a repeated pattern along its length. This segmentation, commonly called serial homology, is not present in the early embryo, such as the ciliated larva of marine annelids, but posterior segments are added during growth. See also ANNELIDA; EARTHWORM; NEMATODA; ROTIFERA.

Arthropoda.—The Annelida are believed to be related to the Arthropoda through the existence of an intermediate primitive form known as *Peripatus*. All of these forms are also similar in a number of embryological ways. To the arthropods, or joint-legged animals, belong the crabs, shrimps, barnacles, centipedes, insects, scorpions, spiders, and others that have been so successful in their invasion of the land, sea, and air. All possess a horny exoskeleton of chitin and, like the annelids, are segmented. The appendages occur as a pair per segment and vary in number among the different groups; they may be modified into walking, swimming, or flying structures and, on the anterior segments of the body, become mouth parts. The aquatic crustacea breathe by means of gills, but land forms such as the insects have a special system of branched tubes (tracheae) that lead air into the deepest tissues. The structure of these animals is extremely complex: the circulatory system may possess a heart; there are glands controlling color, molting, metamorphosis, and other functions; the nervous system is highly organized; and there are specialized sense organs such as compound eyes. This complexity of structure is reflected in the behavior of the arthropods, and some groups of insects like the ants and bees have evolved a highly integrated social life. Arthropods are both very useful and very harmful to man, as food, as agents for the fertilization of plants, as pests of food crops, and as vectors of human disease. See also ARACHNIDA; ARTHROPODA; CRUSTACEA; INSECTS.

Mollusca and Other Phyla.—The phylum Mollusca includes the clams, oysters, chitons, snails, whelks, slugs, squids, and octopuses. Usually there is a calcareous shell, and a prominent feature of the body is a muscular locomotor organ known as the foot. In the squid and octopus this has been modified into a series of tentacles with sucking discs. The latter forms are adapted for rapid swimming in a backward direction by the ejection of water from a mantle cavity. In the other mollusks locomotion is achieved by creeping or burrowing. Breathing is by means of gills and there are well-developed but unsegmented circulatory, excretory, reproductive, and

American Museum of Natural History

Reconstructed fossil amphibian *Diplovertebron*, an animal of the Carboniferous period.

nervous systems. See also MOLLUSCA.

The phyla Entoprocta, Bryozoa, Phoronidea, and Brachiopoda consist of tentacled animals (the last-mentioned group with a pair of clam-like shells and well represented in fossil fauna) that are of interest as problems for the specialist. See also BRACHIOPODA.

Chaetognatha, Echinodermata, and Chordata.

—The remaining three phyla of animals are related. The Chaetognatha consist of some marine arrowworms; the Echinodermata, of the starfishes, brittle stars, sea urchins, feather stars, sea lilies, and sea cucumbers; and the Chordata, of animals with a backbone or the stiff rod (notochord) that precedes it in development. The echinoderms are characterized by the possession of a skeleton of calcareous plates and a water vascular system that is used for respiration and sometimes adapted to locomotion. The condition of many organs, such as the nervous system, is complex. Echinoderms are unsegmented and show radial symmetry. Their ciliated larvae, however, are bilaterally symmetrical and like those of some primitive chordates. The mode of formation of the body cavities as pouches from the gut is remarkably similar in the two groups. For these and other reasons it is believed that the chordates arose in evolution by diversion of the development of the larvae of some animals ancestral to both echinoderms and chordates. See also ECHINODERMATA.

Like the echinoderms, the primitive chordates—sea squirts, sea pork, salps, acorn worms, and lancets—are marine organisms. They do not possess vertebrae as a backbone but have in its place a gelatinous rod that stiffens the body but

allows the bending movements used in swimming. This rod is found, at least in the embryo, in all chordates including man. When vertebrae form, they do so by growing around and displacing the notochord. All chordates also possess, at least in the embryo, gill arches and a dorsal hollow nerve tube. The most primitive living vertebrates, the cyclostomes such as the lampreys and hagfishes, have no lower jaws and no paired fins. The cartilaginous and bony fishes have both jaws and paired fins and, in addition, either small sharp toothlike or bony scales. All fishes breathe by means of gills, but some also gulp air and breathe with lungs. Amphibia usually breathe with lungs in adult life, but a great deal of respiration occurs through their moist skin. Although their four limbs enable them to crawl or hop about on land, amphibia, like the frogs, toads, newts, and salamanders, must, with very few exceptions, return to water to breed. Their eggs develop into tadpoles with gills, and after variable times these larval forms metamorphose into adults. The reptiles, having a moisture-retaining scaly skin, better lungs, and shelled eggs that will develop on land, are better adapted to land life. The birds are very similar in structure to reptiles, the obvious differences being associated with their adaptation to flight. Like the mammals they have a highly developed nervous system and a constant high body temperature. Some primitive mammals, like the duckbill platypus, demonstrate their relation to reptiles not only in many structural features, but especially in that they lay eggs. Nevertheless, they have hair, feed their young with milk, and have many mammalian structural characteristics such as three ear bones. In other mammals, mostly of the Australian region, the young are born in an early stage of development when only a fraction of an inch in length and are nursed in a marsupial pouch on the mother's belly. In the remaining mammals, to which group man belongs, the young, attached by means of a placenta and an umbilical cord, are retained until birth in the uterus of the mother. See also AMPHIBIA; BIRDS; FISH, MAMMALS; REPTILES; VERTEBRATA.

4. Evolutionary Zoology

Fossil Record.—The mammals are now the foremost animals on earth, but this was not always so. Reptiles were predominant in the Mesozoic era, 70 million to 225 million years ago, when dinosaurs and other land, aquatic, and flying reptiles of a great variety of types existed. The only mammals found in the fossil record of that time are a few small insectivorous forms. Before the Mesozoic there were no mammals, no birds, and only a few primitive reptiles. The amphibia had already appeared, however, in Carboniferous times (over 300 million years ago) in the great bogs and swamps that gave rise to the oil and coal deposits of today. The earliest of these amphibia were very similar in structure to the air-breathing fishes that lived in the ponds of those times. This similarity even extended to their primitive limbs, which were not very different from the fins of their fish relatives. Before the Carboniferous there were no true land-living vertebrates, and the fishes of the time were either primitive or, if highly specialized, are not represented among present-day fish fauna. The earliest fishes existed between 300 and 400 million years ago, and study of

their fossil remains indicates that although in most cases they had a heavy armor of bone, they were much like the present-day cyclostome fishes. Before this, only invertebrate remains are found and, even earlier, only the skeletons of shelled protozoa.

This succession in the appearance of animal forms is a proof of the fact of evolution and confirms and amplifies the inferences about the course of evolution made from the study of living animals. Since all previously existing animals are not preserved in rock, and since all so preserved have not yet been found, the fossil record is bound to have gaps. In certain cases, however, the seriation is quite complete. The fossil history of the horse is well known, and it can be demonstrated how for about 50 million years there was a gradual increase in size with consequent improvement in speed and a gradual reduction in the number of toes until, at present, only one toe remains functional on each foot. The fossil history of man is also quite well known and involves improvement in upright gait and an increase in the size of the brain. When the use of implements was learned, man's influence on his environment increased explosively. In tracing such phylogenetic series the paleontologist must recognize the possibility that parallel evolution has occurred independently in several lines. This is known to have occurred in the evolution of the elephants and especially in the evolution of hoofed mammals.

Comparative Embryology.—The order of appearance of the vertebrates, from jawless fishes through the jawed fishes, amphibia, and reptiles to birds and mammals, is the order of increasing specialization of many features, such as the nervous system. This order is in a general way followed in the embryonic development of certain organ systems such as the heart and blood vessels, or the kidneys and the urinogenital ducts. For example, in human embryonic development at early stages the plan of the circulatory system is fishlike even to the extent that there are vessels that pass through gill arches. Only after modification through further development does the circulatory system differentiate into something characteristically mammalian. In fact, the differences between the various vertebrates are found to be less and less as earlier stages of embryology are compared.

Comparative embryology yields many clues concerning the course of evolution. For example, in the mammalian ear there are three bones, while in the ears of all other land-living vertebrates there is only one. The two extra bones in the mammalian ear develop from the same structures that form the jaw articulation in other vertebrates. Thus, in the evolution of mammals a new jaw joint is formed, and bones that were once parts of the jaw lie within the ear and function in hearing. These two mammalian ear bones are said to be homologous with the related jawbones in other vertebrates, the term "homology" referring to the evolutionary relationship existing among structures that are superficially different but fundamentally alike. The single bone in the ear of the lower land-living vertebrates is homologous with the third bone in the mammalian ear; these, in turn, are homologous with a bone that helps support the jaws of fishes. Again, the fins of fishes and the limbs of land-living vertebrates are homologous, but the wings of an insect and a bird are only analogous, having a similar function but

dissimilar structure and origin; they do not possess evolutionary relationship.

In the vertebrates changes during the course of embryonic development are brought about by the influence of one tissue on another. For instance, the nervous system is induced to form by the roof of the embryonic gut underlying it. Transplantation of this inducing gut tissue under the skin of a second embryo causes another nervous system to form. Similarly the lens of the eye is induced to form from skin by the embryonic eyeball. By influencing the course of these processes the hereditary constitution of various animals ensures development true to type. In some primitive chordates and in many invertebrates embryonic development does not involve such a step-wise determination of one tissue by another, but the potentialities of the cells formed by cleavage of the egg are fixed when the cleavage occurs. In this case separation of the cleaving egg into two parts results in two incompletely formed monsters rather than in two perfectly formed but miniature embryos as is the case with amphibia. There is an even broader recapitulation of phylogeny to be observed in the progression from a single-celled egg to the cluster of cells formed by cleavage. This cluster becomes a hollow sphere and, by the inward migration of some of the cells, a two-layered structure. A third, mesodermal layer then appears, and the body cavity forms within it.

Physiology.—Many evidences indicate that life arose in the sea. As the rivers bring salts from eroding soil and rocks into the oceans where water is constantly evaporating, the salt concentration of the sea increases. At the time when animals arose, the sea was more dilute than now. The earliest known vertebrates lived in fresh

water but had in their blood a concentration of salt similar to that of the sea at the time they left it, and to this day that concentration has been roughly retained. The closed blood systems of animals provide watery internal environments for their cells and thereby allow a type of freedom from the outside environment that has reached its culmination in the higher vertebrates. Among them the internal fluid is well buffered against chemical change and carries antibodies that protect the cells against invading viruses and bacteria; the keynote is constancy. Blood possesses an efficient means of transporting oxygen in the hemoglobin of the red blood cells, and it carries carbon dioxide from the cells of the body to the lungs. It also transports food from the gut, where it is dissolved by the action of enzymes formed in the digestive glands. The waste products secured from the tissue fluids around the cells are excreted as the blood passes through the capillaries of the kidney. The blood is moved by the muscular contraction of the heart and arteries and is given direction by the valves of the heart and veins. All of this activity is regulated by the action of the nervous system and the hormones secreted into the blood by the endocrine glands. These two systems control the metabolism of the body, the rate of heartbeat, and the contraction of skeletal and other muscles. These systems in turn respond to stimuli from within the body and from without as perceived by the sense organs. The entire physiology of the animal is adapted to preserve its pattern, but in time aging sets in and is eventually reflected in failure to function.

Heredity and Variation.—The pattern of animal organization is preserved from generation to generation by the reproduction of new individuals, usually by sexual means. When eggs and sperm are formed, the number of chromosomes is reduced to one half of the number normal for the body cells; upon fusion of sperm with egg the normal number is reconstituted. Chromosomes consist of a complex chemical, nucleoprotein, which is capable of existing in an immense number of specific forms. The chromosomes are the hereditary determinants of the cell. For example, the members of one pair of chromosomes in the human male are structurally different from one another and are known as X and Y. A human female has two X chromosomes. One of the X's is included in the egg when the chromosome number is halved; when the sperm is formed, either the X or the Y is incorporated. An X-bearing sperm, by combination with the X-containing egg, will result in a female offspring, while Y-bearing sperm can form only males.

The chromosome is linearly differentiated into sites known as genes. These are the units of heredity that determine all characteristics—sex, eye color, susceptibility to disease, and so on—by influencing the chemical reactions that result in these phenotypic characters. The gene determines the response that the organism can make to the environment in expressing the character. Thus, there is no conflict between heredity and environment; the two mutually interact. Some characters, such as eye color or blood-group type, are rather rigidly determined; others, like size and intelligence, may vary according to the environment within rather broad limits set by heredity. The Mendelian laws governing the transmission of hereditary material are now clearly understood. In accordance with them, sexual reproduction results

in recombinations of genes so that no two offspring (except derivatives of the same egg—identical twins) are exactly alike. This variability is made possible by the fact that genes, although extremely stable, mutate to new conditions at a rate of about once in a million reproductions. Such mutations occur under the influence of radiation and certain chemicals, and for other reasons.

See also HEREDITY.

Natural Selection.—The differentiation among genes, giving rise to variability among offspring, provides the raw material out of which new species are built. With the possible exception of man, who controls his environment more extensively than other animals, no animal species overpopulates the earth, despite a reproductive capacity that is frequently enormous, as in the case of the codfish, which lays millions of eggs in a single spawning. Predators, lack of food, disease, and a multitude of other factors result in the survival of only a few offspring. The better fitted are those who have a greater chance of surviving and reproducing their kind; genes and combinations of genes having the greatest adaptive value are more likely to be spread in future generations. Thus evolution is brought about by the action of natural selection on hereditary variation. Man with his increasing control over the environment is in a position to influence his own evolution. It should be here borne in mind that, in addition to biological inheritance, social inheritance plays an important role.

There is a common explanation of evolution which is alternative to that involving spontaneous variation and natural selection. Usually attributed to Lamarck, it states that the temporary adaptations made by an organism in the course of its life are somehow transmitted to the germ cells and eventually to its offspring. Repeated experimental tests of this explanation have disproved it; the inheritance of acquired characters is simply not a fact. An adaptive environmental modification of an individual's body is important for the individual, but since it is not transmitted to its offspring, it is not the cause of evolutionary change. Furthermore, the Lamarckian explanation is not theoretically sufficient, for it fails to account for the appearance of the ability to undergo temporary adaptations such as the browning of human skin in the sun. The only explanation consistent with all we know about evolution is that involving the action of selection on the variation in heritable traits observed in all families.

As the area occupied by a species increases, regional differentiation into races sets in, due both to the nature of the reproductive process and to adaptation to different ecological opportunities. This differentiation may become so extensive as to introduce biological barriers to reproduction between two geographically or ecologically separated races. Among such reproductively isolated groups an exchange of genes is impossible and as a consequence the two groups would be considered to have differentiated into species. From then on they follow genetically independent evolutionary pathways toward further radiation or to extinction in the face of drastic changes in environment or competition with more successful groups.

Considerable progress has been made in the mid-20th century in the understanding of the process of animal evolution. Among the scientists who have contributed importantly to this progress are Sir Ronald Fisher, Sewall Wright, J. B. S. Hal-

Instinctive Behavior.—Rapid and fascinating progress has also been made in the study of animal behavior, conducted largely by a group of contemporary Europeans, among whom Konrad Lorenz, Karl von Fritsch, Nicolas Tinbergen, and Gustav Kramer are especially prominent. This group of investigators, focusing attention on instinctive behavior, has discovered that certain forms, color patterns, sounds, and movements elicit automatic responses and that animals communicate with one another in this way. Bees, for example, are able to tell other members of their hive of the location of sources of food by performing a "dance" oriented with regard to the location of the sun at the moment. Such sun-directed orientation seems widespread among animals. Birds, for instance, can match the sun's position with the time of the day as they measure it by some internal rhythm or "clock." If there is a discordance with their recent experience, they will

"home" or fly in a direction that brings a familiar agreement of the position of the sun with the time of day. When the time comes for migration, they seek a new alignment in response to a new hormonal condition within their bodies. In this way the young of the Pacific golden plover, newly hatched in Alaska and held back after others have left on their migratory flight, will upon release fly over the open ocean directly to Hawaii without previous experience. All this is instinctive. Other animals, especially mammals such as man, depend much more on what they learn.

Importance of Zoology.—Why should man concern himself with a study of animals? In the first place zoology, like all knowledge, has practical applications. As engineering is to physics and chemistry, so veterinary medicine, animal breeding, fishery and wildlife studies, and the control of crop pests stand in relation to zoology. The kind of knowledge that zoologists are interested in discovering is basic knowledge, that is, knowledge that is generally applicable to many animal forms. As a consequence, human medicine is especially dependent on knowledge gained by zoologists. In recognition of this dependence

four Nobel prizes in physiology and medicine have been given to zoologists: to the German embryologist, Hans Spemann (1935); to the American geneticists, Thomas Hunt Morgan (1933) and Hermann Joseph Muller (1946); and to the English zoologist, Peter Brian Medawar (1960). Most important of all, men are interested in zoology because, as animals, they want to know themselves, their relations, and their past history.

ZOOMORPHISM, zō-ə-môr'fiz-əm (also **THERIO-MORPHISM**), in comparative mythology and folklore and in primitive religion, the assumption of animal form by humans, or representations of such metamorphosis in literature, in symbolism and the arts, and in religious ritual and dance. At its most primitive level, zoomorphism envisages a basic kinship between man and animals in a system of totemism (see **TOTEM**). In lower mythology, and particularly in lycanthropy, men were thought to become werewolves (see **WEREWOLF**) by mere contact with animals, while witches and even the devil himself were believed to enjoy an extension of their own powers by means of their familiar spirits, in whose animal forms, whether of dogs, cats, hares, or others, they were wont to deport themselves. Injury to the familiar brought corresponding hurt to the witch herself. In ancient Egypt many of the gods were conceived in animal form, or as part human, part animal, while in Greek and Roman antiquity the gods were envisioned as being able to transform themselves into animal shape at will. Zeus' assumption of various animal guises to pursue his amours, for instance, constitutes the most celebrated illustration of zoomorphism in literature. Animal shape-shifting has carried over into folktales, such as the Cupid and Psyche cycle and the Swan Maiden stories. See also **ANIMALS**, **SACRED**; **POLYTHEISM**.

WAYLAND D. HAND.

ZORACH, zō'rākH, William, American sculptor and painter: b. Eurburg, Lithuania, Feb. 28, 1887; d. Bath, Me., Nov. 15, 1966. In his youth he lived in Ohio with his parents and then worked in a Cleveland lithographic plant. After studying art in New York City and Paris, he taught at the Art Students League in New York. His early interest was in cubist painting, but about 1917 he turned to sculpture. At first he worked in wood and clay, but later he used stone almost exclusively, employing a method of direct carving that retained the characteristics of his basic material. Zorach is considered a romantic realist, and his work is representational, yet structurally abstract. He is represented in many museums in the United States, such as the Whitney Museum, the Museum of Modern Art, and the Metropolitan Museum of

ZORN, sôrn, Anders (Leonard), Swedish sculptor, painter, and etcher: b. Mora, Sweden, Feb. 18, 1860; d. there, Aug. 22, 1920. After studying sculpture and water-color painting at the Stockholm Academy, he settled in 1882 in London, where he learned etching methods, turned to oil painting, and was a popular success as a portraitist. When he went to Paris in 1887, he experimented with impressionist techniques. Later Zorn traveled widely in many countries, including the United States, where he painted portraits of such notables as Theodore Roosevelt and William Howard Taft. During his lifetime he ranked among the leading Swedish artists and was esteemed especially for his genre scenes of peasant life and paintings of female nudes. Among his sculptures is a statue of *Gustavus Vasa* at Mora. Though he considered his etchings only a pastime, they are now the most highly regarded of his works.

ZOROASTER, zō-rô-ās'tar, founder of the ancient Iranian religion known as Zoroastrianism, and author of the Gathas, 17 religious poems embedded in its scripture, the Avesta: b. 630/618 B.C.; d. 553/541 B.C. The Greeks came to hear of Zoroaster from the magi, the priests of Western Iran, around 400 B.C. The evidence suggests that at that time the magi had only recently been driven to making Zoroaster's teachings

their own, and for reasons of prestige were claiming that the prophet had been of their own stock, a Western Iranian magus. This fiction, in whose context the prophet's name was quoted in its Old Persian form "Zara-ushta," which the Greeks turned into "Zoroaster," gained currency among classical writers; and they continued to describe Zoroaster as a Persian or a Mede even after Hecataeus of Abdera, toward the end of the 4th century B.C., had correctly reported that the prophet, whom he calls "Zathraustes," had been active "among the Ariani." The authors of the Avesta display no acquaintance with Persis or Media, but they often mention a country Aryana Vaejah (Iranian Expanse) which, since they describe it as "the best which God created," was probably their own. Hecataeus' "Ariani" must be recognized as the inhabitants of Aryana Vaejah, and his "Zathraustes" as a Greek rendering of "Zarathushtra" (Camel Driver), the form which the prophet's name has in the language we call Avestan—the language, that is, of the prophet as well as of the "Ariani."

To judge from the linguistic position of Avestan among the other Iranian languages, and from the geographical horizon of the Avesta, Aryana Vaejah lay approximately where the present-day boundaries of Iran, Afghanistan, and Soviet Turkmenistan meet. The country must have lost its independence when Cyrus the Great (r. 559–529 B.C.) incorporated the eastern Iranian regions into the Persian Empire. The ruler of Aryana Vaejah whom Cyrus deposed was presumably King Vishtaspa of the Kavi dynasty—not to be confused with Vishtaspa (Hystaspes), father of Darius I—since no successor of his is mentioned in the sources. Vishtaspa himself, however, looms large in the Zoroastrian tradition as the prophet's protector and friend.

Life.—The Iranian sources on Zoroaster fall into four main groups, which will be referred to as: A, the 6th century B.C. Gathas; B, the remainder of the Avesta, approximately from the 5th to the 3d centuries B.C.; C, the Middle Persian Zoroastrian commentaries, based on information available in and after the 3d century A.D.; and D, Firdausi's Persian epic, the *Shah Nameh* (*Shah-nama*), 10th century A.D. Most biographical data on the prophet are not to be found in sources earlier than C, but allusions in the Avesta sometimes bear them out. Thus the obscure reference in B to "the mountain and the tree of the two who discuss holy matters" is likely to allude to the seven revelations that Zoroaster is said in C to have received from his God between his 30th and 40th year of life. The name Maidyoimanha, laconically cited in the Avesta, belonged according to C to Zoroaster's cousin and first convert. Even the illustrious converts Jamaspa and Frashaoshtra, often mentioned in A and B, are identified only in C—the former as Vishtaspa's grand vizir and husband of Zoroaster's youngest daughter; the latter as Jamaspa's brother and father-in-law of the prophet.

Zoroaster's year of birth can be calculated from a date given in C as either 630, or 628, or 618 B.C. From the account of C it appears that the prophet reached the age of 77 and that the turning point of his career occurred at the age of 42, when he succeeded in converting Vishtaspa. The rebuffs which, according to C, he suffered earlier are reflected in a number of Catholic verses: hostile priests and teachers are mentioned; a prince refused him hospitality; he did

not know where to turn; and a salary he had been promised was not paid. But after Vishtaspa with his family and court had been won over, the position of the prophet and the success of the new faith were assured.

Zoroaster's see is stated in B to have been Raga. This district, although usually identified with an area near present-day Teheran, should rather be looked for, on the strength of its position in an Avestan list of countries, in eastern Afghanistan. Raga may have been the home district of the prophet, whose language, as attested in A, has distinct vernacular traits. Unfortunately the location of the river Drja, near which according to B stood the house of Zoroaster's father Pourushaspa, is unknown.

Several enemies of Vishtaspa's are mentioned in the Avesta. Against one of them, Arjataspa, king of the Hyaonas, Zoroaster's protector led, according to C and D, a prolonged religious war, of which these late sources give detailed accounts. Although in the end the Hyaona invaders were routed, this happened only after the prophet had fallen a martyr at their hands.

Thought.—Among the Iranian contributions to world thought Zoroaster's is not only the earliest but also the one which ranks highest. Despite the immense difficulties of interpretation, no one who has studied the prophet's utterances can escape the impression that he had anticipated, and possibly originated, some of the assumptions of Greek, Jewish, and early Christian thinking. Although the extent to which these three sources of Western civilization were indebted to him eludes us, his conception of God and of man's destiny still seems remarkably akin to the one which prevails in the West.

The chief features of Zoroaster's vision are his incisive solution of the problem of evil, of which he absolves God without detracting from His omnipotence; the pivotal significance of Truth in his system; the dignity he confers on man as a free and responsible agent; and the belief in a Savior and a resurrection into a state of eternal perfection. Such a vision, in the 6th century B.C., only a powerful mind could have conceived. Intellectual power also pervades his versification, which, although based on inherited patterns, stands out unmatched in originality and concentration among the early products of Indo-European poetry.

ZOROASTRIANISM, zō-rō-ās'trē-ən-iz-əm, the religious system of ancient Persia, founded by Zoroaster sometime between the 9th and 6th centuries B.C.¹ and still professed by some 20,000 Gabars in Iran and 120,000 descendants of emigrants (the Parsis) in Bombay, India, and surrounding towns. Its sacred book is the Avesta (Zend-Avesta); there are also treatises in a less ancient language, Pahlavi. See PARSIS; ZEND-AVESTA; ZOROASTER.

History.—Zoroaster's reform seems to have originated in northeast Iran, whence it spread

¹ Editor's Note: Some authorities date Zoroaster more definitely in the 7th–6th century B.C.

southward and westward during the Achaemenid period (6th–4th centuries B.C.), although it is not quite certain that Darius I and his successors, who worshiped Ahura Mazda, were followers of Zoroaster. After Alexander's conquest of Iran (331 B.C.), Greek and Semitic elements invaded the religion until toward the end of the Arsacid period (c. 250 B.C.–226 A.D.) the native civilization began to revive. Then with the advent of the Sassanid dynasty in 226, Zoroastrianism was established as the official religion of the Iranian Empire. It had to combat not only Christianity but also Manichaeism, a gnosis made up of Greek, Jewish, and Iranian elements, whose founder Mani was persecuted by Karter, the Zoroastrian high priest, and put to death under King Bahram I (r. 273–276).

At the beginning of the 6th century A.D. a new, communistic religion was preached by Mazdak and favored by King Kavadh I, whose son Khosrau I (r. 531–578), however, restored the traditional order, defined orthodoxy, completed the Avesta, and consolidated the Zoroastrian church. After him the Sassanid empire declined until it was destroyed by Mohammed's followers in 641. Islam tolerated the ancient religion in principle, but conversions, either by persuasion or by force, were massive in some provinces. However, there were spots of survival, notably in Fars, where the works in Pahlavi were produced. They purported to salvage as much of the religion as was possible in the face of approaching disaster.

From the 11th century onward the movement of national revival in Iran was usurped by chiefs of Turkish origin, the Ghaznavids, Ghurids, and Seljuks, who leaned on orthodox Islam against both Sh'ism and Zoroastrianism. Firdausi's *Shah Nameh*, the great epic sponsored by Mahmud the Ghaznavid (r. 999–1030), extols the glorious past of Iran, but Zoroastrianism plays very little part in it, and the entire poem is placed under the invocation of Allah. Zoroastrianism partly survived in the form of elements amalgamated into the Muslim religion of Iran, but as an autonomous religion it persisted only in a few remote places like Yazd (Yazd) and Kerman. One or more parties of Zoroastrians left Iran for the island of Hormuz (Ormuz) in the Persian Gulf, then for India, where they settled in Gujarat and later spread to Bombay. There they were called Parsis (Persians) after their country of origin, and their religion was called Parsism. Contact was lost with their Iranian brethren the Gabars (literally "infidels," a name given them by the Muslims), but it was restored in 1477 for three centuries in an exchange of letters and visits. As a consequence of this intercourse Parsism split into two sects over a question of calendar.

Ritual.—The chief ceremony of Zoroastrianism is the *yasna* or sacrifice, an offering of *haoma*, the sacred liquor (in India, *soma*), together with water and milk libations in the presence of a fire, in honor of Ahura Mazda (Ormazd, Ormuzd) and lesser deities and for the benefit of the dead or the living. In the course of this ceremony the main part of the Avesta is recited, including Zoroaster's Gathas. The *yasna* is essentially a life rite, destined to promote the forces of life against the demons who are supporters of death and evil. In former days the slaughtering of animal victims was part of the ritual. Although condemned by Zoroaster, at least in its cruelest forms, animal sacrifice survived well into medieval times but is now extinct.

Fire is an object of special reverence. It is kept burning in the temple and fed at fixed intervals, and embers from all the fires of the community are brought to it periodically for regeneration. The installation of a new fire temple is, especially in its final phase, one of the major festivals of the Parsis; the fire is enthroned as a king. In ancient times, fire was an instrument of ordeal, and it was taught accordingly that in the world to come, with the final renovation of all things, fire would help in distinguishing the good from the wicked. It was therefore associated with truth or justice. Moreover, fire was thought to be all pervading as a kind of life fluid, coming down from heaven in the lightning, which penetrates the waters and feeds the plants (from which fire can be extracted through friction), which in turn feed the animals and man and give them animal warmth. This ancient theory, which also appears in the Upanishads, was especially developed in Iran in the notion of Xvamah, an emanation of the sun that descends upon each individual but particularly upon kings and saints and resides in their heads, from which it radiates in the form of the nimbus or rays. This concept seems to have been passed on to Buddhism, Christianity, and Islam.

The most conspicuous feature of Zoroastrianism, apart from the fire ritual, is the practice of disposing of the dead by exposing them to birds of prey (formerly also to dogs) in so-called Towers of Silence, to avoid defiling the earth, fire, or water. There are several ceremonies of purification, entailing washings with water, sand, and bull's urine, and the presence of a "four-eyed" dog (with two dark patches above the eyes), which is also used in the funeral rites. Every Zoroastrian has to be received into the fold of the "good religion" by donning a sacred shirt and a sacred thread or *kusti*, which will never leave him again even in death and to which symbolic values are attached.

Ethics.—Two principles form the basis of the Zoroastrian code of ethics: the maintenance of life, and the struggle against evil. In order to maintain life, one must raise cattle and till the earth, and marry and have children. Asceticism and celibacy are condemned. To fight evil is to combat the demons and all beings, either human or animal, belonging to them. If the two principles come into conflict, the second one prevails. Each man can and must choose freely between good and evil.

Dualism.—A central feature of Zoroastrianism is its doctrine of dualism, which personifies the opposing principles of good and evil and recognizes the universal sway of these hostile forces. The powers of good are led by Ahura Mazda (the Wise Lord); those of evil by Ahriman (Angra Mainyu; the Evil Spirit). Each has an array of warriors. On one side are bands of angels and archangels; on the other, companies of demons and archfiends. Under the general name of Amesha Spentas (Immortal Holy Ones) are grouped the six archangels who personify fundamental virtues and abstract ideas, and whose names represent Good Mind, Excellent Truth, Wished for Kingdom, Devotion, Wholesomeness, and Non-Death. In addition there are a number of angels and lesser divinities called Worshipful Ones. In the opposing army a crowd of lesser fiends and demons (including the daeva Aeshma) accompany the six archfiends. See also PERSIAN MYTHOLOGY.

Millennia.—According to Zoroastrianism, the world's history is a contest between good and evil, or light and darkness, which will endure for 12,000 years, divided into four equal periods. The first period is one of spiritual existence. Conscious that Ahriman lives, Ahura Mazda makes the world as a spiritual creation before it assumes material form. When Ahriman discovers his enemy at work, he arouses to life his army of demons and fiends. In the second epoch Ahura Mazda creates the material world, which is invaded by Ahriman and his cohorts. The third period marks the contest for mastery between the rivals and the battle for the human soul until Zoroaster is born. The fourth and last epoch then begins. The prophet and his three sons, to be born in ages to come, the last being the Saoshyant, or Savior, pre-empt the final eon. As the world enters the stage of regeneration, with the resurrection and final judgment, Ahriman will form his hosts for a final battle. They will be defeated, and good will reign forever.

There was an age-long discussion during the Sassanid period between the pure dualists and those who recognized, above the good God and the evil Demon, a unique principle, Zurvan, or Infinite Time. In fact, although the Avesta has little trace of it, Zurvan was the supreme god in Iran at the time of Mani (d. 276 A.D.), for the Manichaeans never called their god Ahura Mazda but, sometimes, Zurvan. Ahura Mazda was in Manichaeism the name of the primal man. See also MANICHAEAENS.

Resemblances in Greek Philosophy, Judaism, and Christianity.—There are striking parallels between Iranian doctrine and pre-Socratic speculation in Greece. The chief of these, perhaps, is that between the *logos*, or "true sentence," as a cosmic principle, and *asha-arta* (in Vedic India, *ṛta*), the "true prayer," as universal law; and the association of fire with both. Additional traces of Iranian influence may be sought in Anaximander, Empedocles, Plato, and others.

Although a definite borrowing is still impossible to prove, the resemblances between Zoroastrianism and Judaism are numerous and important and probably took shape during the Exile. First, the figure of Satan, originally a servant of God, appointed by Him as His prosecutor, came more and more to resemble Ahriman, the enemy of God. Secondly, the figure of the Messiah, originally a future king of Israel who would save his people from oppression, evolved, in Deutero-Isaiah for instance, into a universal Savior very similar to the Iranian Saoshyant. Thirdly, the entities that came to surround Yahweh, such as His Wisdom and His Spirit, are comparable to the archangels escorting Ahura Mazda; the Spirit, in particular, is comparable to Spenta Mainyu. The six powers of God in Philo Judaeus' speculations are also comparable to the Iranian archangels. Since the latter were known to the Greeks, it is by no means impossible that Philo had heard about them. In fact, he mentions as quite familiar the Persian doctrine of God's virtues. But the likeness is limited to general analogy.

A more exact parallel is provided by the doctrine of the Two Spirits. Before the discovery of the Dead Sea Scrolls in 1947, there were only scanty traces of this in known Jewish literature, but the Manual of Discipline in the Dead Sea Scrolls provides a whole small treatise on the subject. One is immediately reminded of the doctrine of the Two Spirits in Zoroaster's Gathas, the

ethical and eschatological dualism of which can be detected here; but the predestination of the Two Spirits in the Jewish document is contrary to Zoroastrian free choice. One must therefore look for another Iranian source, outside the Avesta, to explain the absence in the Jewish document of what was the essence of Zoroaster's message: the part of the Two Spirits in the drama of choice. Predestination in contrast to free choice, the identification of the Two Spirits with light and darkness, and the explicit creation of these spirits by God leads back to the Zurvanist myth of a god of time or fate, father of the light Ahura Mazda and the dark Ahriman. Since this is the form under which the Jews presumably must have known Iranian religion at the time, the conjecture of borrowing seems confirmed.

Other points of comparison between Iran and Israel include the doctrine of the millennia; the Last Judgment; the heavenly book in which human actions are inscribed; the Resurrection; the final transformation of the earth; paradise on earth or in heaven; the ecstatic ascent of Enoch or Arda Viraf (an Iranian sage) into the heavens; hell; the souls of the animals accusing man in the Slavonic Enoch, like the soul of the ox in the Gathas; and, finally, in Tobias (Tobit), the demon Asmodeus, alias daeva Aeshma.

Christianity seems to owe many features to Iran, over and above those it inherited through Judaism. Among others are probably the belief in guardian angels, resurrection, and in the heavenly journey of the soul.

ZORRILLA Y MORAL, thór-rē'lyā ē mō-rāl', José, Spanish poet and dramatist: b. Valladolid, Spain, Feb. 21, 1817; d. Madrid, Jan. 23, 1893. He was educated in Madrid, studied law in Toledo and Valladolid, but then turned to literature. The publication of *Poesías* (1837) won him immediate recognition as the leading figure of romanticism in Spain. In 1845–1846 and 1848–1855 he lived in France and then went to Mexico where, under the protection of Emperor Maximilian, he was commissioned to found a national theater. The fall of Maximilian brought his mission to an end, however, and Zorrilla returned to Spain, where he spent the rest of his life, first in Valladolid, then in Barcelona, and finally in Madrid. Between 1871 and 1873 he suffered bitter poverty despite the success of his plays, but eventually he received a government pension of 30,000 reales, and on June 21, 1889, in Granada, he was crowned poet laureate of the nation. An account of his life, though not strictly reliable, is his own *Recuerdos del tiempo viejo* (2 vols., 1880–82).

Like other writers in great popular esteem, Zorrilla has enjoyed high and low appraisals in literary history. There is no doubt that his work in lyric, narrative, and dramatic forms represents the decisive arrival of romanticism in Spain. His lyric poems and many "legends," or ballads, represent new stages in the descriptive powers of the

language and genuine remakings of traditional epic and legendary elements in Spanish history despite their excessive metrical fluency, copious stanzaic sweep, and occasionally distracting moralizing. *Cantos del trovador* (1841) is the first of several collections of verse legends. His dramatic work suffered from his great capacity to improvise and from the haste and quickness of his composition; but *El zapatero y el rey* (1840) and *Traidor, inconfeso y mártir* (1849) are plays in which the thematic preoccupations of romanticism—national tradition and religious belief—are given effective presentation. His *Don Juan Tenorio* (1844) gives the theme of the eternal seducer as archetype such surface attraction that it is likely to remain a popular masterpiece.

EUGENIO VILLICAÑA.

ZOSHCHENKO, zó'shchën-kô, **Mikhail Mikhailovich**, Russian writer: b. Poltava, Russia, 1895; d. Leningrad, July 22, 1958. His humoristic sketches and tales made him widely popular in the USSR in the 1920's. His satirical stories dealt with the pettiness of Soviet citizens and the incongruities of the new way of life. The narrator of these realistic descriptions spoke a peculiar idiomatic language, called later "Zoshchenko's tongue." In the 1930's Communist critics accused him of anti-Soviet feelings. In 1943 the publication of his psychological, introspective novel *Pered voskhodom solntsa* (Before the Dawn) was stopped by governmental order, and in 1946 he was formally accused by party leaders and expelled from the Union of Soviet Writers. He hardly published anything after the "purge" and died in solitude and oblivion. Selections from his works appeared, however, after Stalin's death.

Zoshchenko is certainly the leading humorist of Russian post-Revolutionary literature, and his puns and anecdotes have amused millions of readers. The figures of half-baked Communists and lower middle-class knaves and bureaucrats portrayed in his snapshots of Soviet reality have become symbolic of certain Russian social groups of the period. A selection of his stories in English translation is *Scenes from the Bathhouse and Other Stories of Communist Russia* (1961).

MARC SLONIM.

ZOSIMUS, zō'sī-mās, **SAINT**, pope: d. Rome, Italy, Dec. 26, 418; r. 417–418. Little is known of his antecedents. The *Liber pontificalis* calls him Greek, but his father's name, Abraham, has caused some to consider him originally Jewish. On the morrow of his election as pope (consecrated March 18, 417) Zosimus conceded extraordinary powers of superintendency over the Gallic church to Patroclus, bishop of Arles, who was in high favor at the court of Ravenna and who, it has been thought, may have exercised preponderant influence in the succession of Zosimus to the papal chair after the death of Innocent I. This action was resisted by the Gallic bishops. Further complications soon arose in the Pelagian controversy (see PELAGIANISM), and Zosimus became embroiled in an interchange on this subject with the bishops of Africa. Even at Rome itself, dissatisfaction was felt with the stormy administration of this pope, and the urban clergy took their grievances to the emperor at Ravenna. Zosimus had a strong sense of the rights of the Apostolic See, which he ceaselessly strove to enforce; but lacking tact and finesse, his efforts had the contrary effect and opened the way for the state to intrude into

the affairs of the Roman Church, thus nullifying the prudent work of his predecessors. One of his decretals, addressed to Hesychius of Salona, was given place in old canon law. It forbade monks or laymen to be promoted to episcopal rank without having passed through subordinate offices for a determined time.

ZOSIMUS, Byzantine historian: fl. 5th century. A count and a lawyer connected with the imperial treasury, he appears to have been also an ancient Edward Gibbon, for he wrote his *Historia nova* (New History) to demonstrate the decline of the Roman Empire. The work, in six books, starts with Emperor Augustus' reign (27 B.C.–14 A.D.) and ends with Alaric I's sack of Rome (410). His professed devotion to the pagan divinities and consequent animus against Christianity led him to ascribe the empire's gradual decay to Christianity's antagonism toward paganism. Apart from this, Zosimus is generally trustworthy, displays good historical judgment, and writes clearly and concisely. Although his work sometimes shows scant interest in chronology, it is among our chief authorities for the history of the 4th century.

P. R. COLEMAN-NORTON.

ZOSTERA. See EELGRASS.

ZOUAVES, zōō-ävz', originally a French infantry corps recruited in Algeria from the Zwawa tribe of Kabyles after the French conquest in 1830. They had previously served the Algerian deys as mercenaries. By about 1840 the Algerians were eliminated from the corps and replaced by French soldiers, who retained the native dress. Papal Zouaves were recruited from French soldiers at Rome in 1860 under Gen. L. C. Léon Juchault de Lamoricière, a former commander in Algeria, to defend the temporal sovereignty of the pope. They were unsuccessful against the Italian troops at Rome in 1870, and after serving in France during the Franco-Prussian War, they were disbanded in 1871. Several regiments of volunteers in the American Civil War were called Zouaves because they adopted the dress and drill of the French Zouaves (see ELLSWORTH, ELMER EPHRAIM).

ZOUCHE, zōōsh, **Richard**, English authority on civil law: b. Ansty, Wiltshire, England, 1590; d. London, March 1, 1661. Educated at New College, Oxford, he was admitted as an advocate of Doctors' Commons in 1617, and in 1620 became regius professor of civil law at Oxford. In addition to his university duties he had a large practice in London. In 1641 he was made judge of the High Court of Admiralty. Zouche was a Royalist, though not a pronounced one, during the

Civil War; and although he was replaced in the judgeship in 1649, he was appointed by Oliver Cromwell to a special commission of oyer and terminer, and retained his academic appointments. After the Restoration he was a member of the commission that reinstated the professors and fellows of Oxford who had been removed under the Protectorate.

Zouche's writings include a descriptive poem, *The Dove, or Passages of Cosmography* (1613); a comedy, *The Sophister* (1639); and many professional legal works, most important of which are *Elementa jurisprudentiae* (1629), a general system of legal science, and *Juris et judicii fecialis . . . explicatio* (1650), regarded by critics as the first treatise containing a systematized arrangement of international law.

ZRENJANIN, zřen'yä-nin, city, Yugoslavia, in Vojvodina, northern Serbia, 26 miles east-northeast of Novi Sad. It is a rail center on the Belgrade-Kikinda Railroad, and a port on the canalized Begej (Bega) River. Manufactures include dried beet pulp, sugar, agricultural machinery, molasses, and dairy products. Other industries are flour milling, brewing, carpet making, and vegetable canning. The city was called Veliki Beckerek until the 1930's, and Petrovgrad thereafter until about 1947. Pop. (1971) 60,201.

ZRINYI, zřinyi, **Miklós** (Croatian **NIKOLA ZRINJSKI**), Croatian-Hungarian soldier: b. 1508; d. Sziget (now Szigetvár), Hungary, Sept. 7, 1566. Member of an old and eminent Croatian noble family, he distinguished himself at the siege of Vienna in 1529 and in campaigns against John Zápolya and the Turkish sultan Suleiman the Magnificent.

During the contest for the Hungarian throne between Zápolya's son and successor John Sigismund and the Habsburgs, John Sigismund appealed to Suleiman for assistance. Zrinyi as ban (viceroys) of Croatia, an autonomous territory loyal to the Habsburgs, defended his banat against a Turkish army led by Suleiman himself. When Suleiman besieged Sziget in 1566, Zrinyi had only 3,000 defenders against the enemy hosts, but they resisted from August 5 to September 7. In a final desperate battle Zrinyi and the few survivors of his garrison were killed. But Suleiman also died during the siege, and his army, having suffered heavy casualties, advanced no farther into Europe. Zrinyi's glorious feat of arms is the subject of an epic, *Szigeti veszedelem* (1651), written by his great-grandson of the same name.

ZSCHOKKE, chō'kə, (**Johann**) **Heinrich** (**Daniel**), German-born Swiss author and publicist: b. Magdeburg, Germany, March 22, 1771; d. Aarau, Switzerland, June 27, 1848. After seven years as a tutor, itinerant playwright and actor, and student of theology, humanities, and law at the University of Frankfurt an der Oder, Zschokke settled in Switzerland in 1796. He wrote a history of the Grisons (1798), served as head of the department of public instruction in Aarau, and was government commissioner of several cantons. In 1800 he established order in the Italian sections of Switzerland and in 1804 became a member, later head, of the federal board of mines and forests.

Zschokke achieved fame as a reformer and agitator as well as a publicist, editor, and historian. *Des Schwetzerlandes Geschichte* (1822) was a

popular work of history. For the rejuvenation of the moral and political life of Switzerland, turbulent in the 1820's and 1830's, much credit is also due him. But Zschokke's greatest significance today lies in his imaginative and devotional writings. As a prolific author of tales he became known throughout Europe, England, and America (*Der Creole*, *Alamontade*, *Abenteuer der Neujahrsnacht*, and *Der zerbrochene Krug* are representative). The romance *Abällino, der grosse Bandit* (1793; Eng. tr., *The Brave of Venice*, 1805, by Matthew G. Lewis, who also turned it into the melodrama *Rugantino*, 1805) was dramatized and held the stage for generations. The later rationalist-pietist verse collections, *Stunden der Andacht* (8 vols., 1809-16; Eng. tr., *Hours of Meditation*), went through scores of editions. The works of few foreign authors have been translated into English as much as those of Heinrich Zschokke.

EDWIN H. ZEYDEL,
Professor Emeritus of German, University of Cincinnati.

ZSIGMONDY, zhig'mōn-dē, **Richard**, German chemist: b. Vienna, Austria, April 1, 1865; d. Göttingen, Germany, Sept. 23, 1929. He studied chemistry and physics at the universities of Vienna and Munich. August Kundt, at Berlin, called his attention to the colors produced when organic solutions of gold are painted on porcelain. Work on this problem led to Zsigmondy's fundamental research on colloids, for which he was awarded the Nobel Prize in chemistry in 1925.

Zsigmondy began his research with an investigation of ruby glass and ceramic colors produced by the dispersion of colloidal gold. The fact that the colors seemed to be independent of the chemical compounds in which the gold existed led him to suspect that the physical state of the gold was the basic factor. In order to investigate this state directly, he and Henry F. W. Siedentopf of Jena invented (1903) the slit ultramicroscope, with which gold particles of a diameter of one ten-millionth of a millimeter could be seen. Zsigmondy was soon able to show that the stability of gold colloids depends on a negative electrical charge associated with each particle; if this charge is removed, the system coagulates. As the particles grow larger, the color changes, and the relationship between color and particle size becomes clear. Coagulation can be halted at any time by the addition of protective colloids. The laws of colloid action were made evident by this research, and colloid chemistry became an exact science. From 1907 to 1929 Zsigmondy served as director of the Institute for Inorganic Chemistry at the University of Göttingen. He published an account of his life work in a volume entitled *Zur Erkenntnis der Kolloide*.

L. PEARCE WILLIAMS.

ZUARA, zwä'rə, town, Libya, in western Tripolitania, a port on the Mediterranean Sea, 65 miles west of Tripoli. It is a rail terminus and an oasis. The people specialize in camel breeding, sponge fishing, olive-oil pressing, and flour milling. Cereals, vegetables, olives, dates, and esparto grass are raised. Pop. 14,578.

ZUBAYR, Rahama. See Zobeir, RAHAMA PASHA.

ZUCCARELLI, tsōōk-kä-rē'lē, **Francesco**, Italian painter: b. Pitigliano, Tuscany, Italy, Aug. 15,

1702; d. Florence, Dec. 30, 1788. Although his fanciful landscapes no more than echo the work of Marco Ricci, he had studied assiduously with Pietro Nelli in Rome. He found an unvarying style that makes his pictures hard to date and his fame difficult to understand. He went to Venice about 1730, and by 1751 he was, according to his contemporary Richard Wilson, "a famous painter of this place." Joseph Smith, British consul there, patronized him and doubtless suggested his first English stay: 1752 to 1762; his second stay lasted from 1765 to 1771, during which he became one of the founder members of the Royal Academy (1768). In 1772 he was elected president of the Venetian Academy.

WALLACE BROCKWAY.

ZUCCARO, tsōōk'kä-rō, the name of two Italian painters:

TADDEO ZUCCARO: b. Sant'Angelo in Vado, Duchy of Urbino, Italy, Sept. 1, 1529; d. Rome, Sept. 1 or 2, 1566. Before his early death he had established himself, with amazing good fortune (in view of his meager talent), as an influential mannerist painter. He undertook important decorative frescoes for the Farnese both in their Roman palace and in their villa at Caprarola and also undertook to do frescoes in the Sala Regia of the Vatican. He was buried in the Pantheon, close to Raphael.

FEDERICO ZUCCARO: b. Sant'Angelo in Vado, Italy, 1542 or 1543; d. Ancona, July 20, 1609. The younger brother of Taddeo, he was the more considerable artist, and possibly the most renowned painter working in Rome during the second half of the 16th century. He studied with Taddeo and was early associated in some of his enterprises; he also worked much in Venice at this time. In 1566 he went to Rome to decorate the Sala Regia, but quarreling with members of the papal court, he fled first to France, then to the Low Countries, and finally to England. It was once believed that he remained there four years, but six months (1574-1575) comes closer to the truth. His portraits of both Queen Elizabeth and the earl of Leicester are lost; the drawings for them are in the British Museum. That he painted many portraits in England is a legend that is not yet dead, and as Sir John Summerson writes in *Painting in Britain: 1530-1790* (1953): "His name, taken in vain, is to be found on labels in most of the great houses of England." It took him five years to finish Giorgio Vasari's frescoes in the dome of the cathedral in Florence, after which he moved around a good deal. His career in Spain was clouded, and his frescoes in the Escorial were soon superseded. In 1595, under a papal charter, he reinstituted the Accademia di San Luca in Rome, the prototype of the Royal Academy, founded almost two centuries later in London by Sir Joshua Reynolds.

WALLACE BROCKWAY.

Author and Consultant to the Bollingen Foundation.

ZUCCHETTO, tsōōk-kēt'tō, the skullcap of a Roman Catholic ecclesiastic. That of a pope is white, of a cardinal red, of a bishop purple, and of other ranks, black.

ZUCCHI, tsōōk'kē, **Antonio (Pietro)**, Italian painter: b. Venice, Italy, May 1, 1726; d. Rome,

Dec. 26, 1795. He completed his studies with Jacopo Amigoni, after which he toured the peninsula, studying and often drawing the ancient monuments. His professional alliance with the brothers Adam brought him to England, where he was an associate of the Royal Academy from 1770 to 1784. Although he did not marry the painter Angelica Kauffmann until 1781, he often helped her in carrying out her commissions. He also worked independently. Ceilings were his specialty. Good examples of his skill may be seen at Osterley Park, Kenwood House (London), Syon House, and various London houses. His work cannot always be distinguished from his wife's. After their marriage, Zucchi and his wife lived in Rome. In 1790 a paralytic stroke ended his active career.

WALLACE BROCKWAY.

ZUCCHINI, zōō-kē'nē, a variety of summer squash of the Italian marrow type, belonging to the Cucurbitaceae family, of the genera *Cucurbita pepo*. The bush-type plant has short stems with deeply lobed leaves. The fruits are relatively short, cylindrical, and blocky, of a creamy gray-green color, with darker green markings. The flesh is light greenish white when the fruits are small. In season comparatively early, the fruits are used for immediate consumption when young and immature, and boiled or steamed unpeeled. Zucchini is rich in vitamin A, with considerable amounts of riboflavin, iron, and calcium. The standard variety used by growers is the black zucchini, with fruits colored a deep dark green or nearly black. Troublesome pests are the squash bug, squash vine borer, and cucumber beetle. Some of the common diseases are bacterial wilt and mosaic. See also SQUASH.

HARM DREWES.

ZUCKMAYER, tsōōk'mī-ər, **Carl**, German playwright, novelist, and poet: b. Mackenheim, Germany, Dec. 27, 1896; d. Visp, Switzerland, Jan. 18, 1977. He began writing poetry while in the German army in World War I. Although he also wrote novels, he is best known as a dramatist, and many of his plays have been filmed. His expressionistic play *Kreuzweg* was produced in 1920, followed by the exuberant utopian comedy *Der fröhliche Weinberg* (1925) and others, notably the antimilitarist satire *Der Hauptmann von Köpenick* (1931; Eng. tr., *The Captain of Köpenick*, 1932). His work was banned by the Nazi regime in 1933, and after living in Austria and Switzerland, he emigrated to the United States and remained in Vermont until 1946, when he returned to Germany. His later plays are considered his best, including the anti-Nazi drama *Des Teufels General* (1946); *Der Gesang im Feuerofen* (1950), about the French resistance movement; and *Das kalte Licht* (1955), about an atomic spy. *A Part of Myself* (1970) is his autobiography. His screenplays include *The Blue Angel* and *Rembrandt*.

ZUG, tsōōkh, canton, Switzerland, bounded by the cantons of Zürich on the north, Schwyz on the east and south, and Lucerne and Aargau on the west. With an area of 93 square miles, it is the smallest undivided canton in the country. The Lake of Zug, its most prominent natural feature, was an important link on a medieval trade route. The town of Zug, at the lake's northeast corner, is the capital and the only

town of size. The surface of the canton is mountainous in the south and southeast, where the Rossberg (5,196 feet) stands along the Schwyz border, and slopes gradually north and west until it becomes comparatively flat. A small lake, the Agerisee, lies in the southeast, and just east of its southern tip is Morgarten, scene of a memorable victory of the Swiss over the Austrians on Nov. 15, 1315. Much of the land is in farms, principally for stockbreeding, dairy products, and fruit. Industry is largely concentrated in the town of Zug, with textiles in Baar and papermaking in Cham. The inhabitants are German speaking and Roman Catholic, and Zug was one of the Catholic cantons that joined the Sonderbund (q.v.) in 1843. It belonged to the Habsburgs from 1273 until 1352, when it joined the Swiss Confederation, but the Habsburgs did not formally renounce their claims until 1389. Pop. (1960) 52,489.

ZUG, town, Switzerland, capital of Zug Canton, at the northeast corner of the Lake of Zug, 14 miles south of Zürich. The older portion of the town contains many fine houses dating from the 16th century. There are four fortified watch-towers and traces of old defensive walls. The Late Gothic Church of St. Oswald, begun late in the 15th century, has some fine choir stalls. In the 16th century town hall is a historical museum. The Capuchin monastery, of the same period, has a notable altar painting by Denis Calvaert. Industry includes the manufacture of chemicals, tobacco and cigars, metalware, and a weaving mill. There is a station for the culture of fish, and the town is a military depot. In 1435, 1593, and 1887 parts of the town slid into the lake. Pop. (1960) 19,792.

ZUG, Lake of, lake, Switzerland, touching the cantons of Zug, Schwyz, and Lucerne, southwest of the Lake of Zürich and north of the Lake of Lucerne, at an altitude of 1,357 feet. The lake is about 9 miles long from north to south and 2½ miles wide, with an area of 15 square miles and a maximum depth of 649 feet. The Rigi (5,908 feet) rises boldly to the south, with the Rossberg to the east of it, and farther north on the east shore stands the high plateau of the Zugerberg. Elsewhere the lake is surrounded by gently sloping hills. The Lorze River flows through the north end of the lake, entering from the east and leaving to the northwest, and the Kiemen promontory protrudes from the lake's western shore. The principal town on the lake is Zug, at the northeastern corner.

ZUIDER ZEE, zī'dər zā', Du. zoi' dər zā', a former shallow inlet of the North Sea in the northern and central Netherlands. It was once a lake, known in ancient times as Flevo Lacus. In the 13th century a major flood breached the land between the lake and the North Sea, leaving a series of islands across the mouth of the inlet. The major resulting islands were Texel, Vlieland, Terschelling, Ameland, and Schiermonnikoog, collectively known as the West Frisian Islands. The inlet was 80 miles long, and several channels, the principal being Marsdiep and Boommensdiep, still provide communication with the North Sea.

Reclamation of the Zuider Zee has been a major project in the Netherlands since the 17th century, but substantial work did not begin

until 1920. The project proposed reclamation of 500,000 acres in five separate ^{termed} polders, and the creation of a freshwater lake to be known as the IJsselmeer. In 1932 the Zuider Zee was split into two main portions, the IJsselmeer and the Waddenzee, with the completion of a dike, the Afsluitdijk, which connects the provinces of North Holland and Friesland and seals off the Waddenzee and

Engelhard from Montmeyer

Highway on the Afsluitdijk, 20-mile-long dike separating the IJsselmeer from the Waddenzee, a branch of the North Sea. Dike is part of the Zuider Zee reclamation scheme.

the North Sea. Locks permit the passage of barges from the Rhine River. Before World War II the northwest (Wieringermeer) and northeast polders were completed and prepared for cultivation. At the time of the German invasion of the Netherlands in 1940, work was proceeding on the remaining polders. Later in the war the Germans breached the dikes in order to delay the Allied advance, and much of the reclaimed land was flooded, but it was drained once more by the end of the war. In 1954 a 16-mile dike, linking the mainland town of Harderwijk with the new town of Lelystad on reclaimed land, was completed, and by 1956 the southeast polder (East Flevoland) was enclosed by a 66-mile dike extending from Harderwijk. When the entire project is completed, a 12th province of the Netherlands, Zuiderzeeland, will be formed.

ZULIA, sōō'lyä, state, Venezuela, in the northwest part of the country, 24,360 square miles in area. Shaped like a horseshoe, it lies around the entire shore of Lake Maracaibo, except where a strip of the State of Trujillo cuts in at the southeast. On the north it fronts the Gulf of Venezuela, and a narrow tongue of territory extends along the Guajira Peninsula. Colombia is to the west, with the Sierra de Perijá along the border. Of the rivers draining into Lake Maracaibo, the Catatumbo is most important. The northern plains are dry and hot, but in the lowlands of the south the climate is humid. The Venezuelan oil industry centers in Zulía, which is one of the world's major petroleum regions. On the lake's eastern shore, where derricks rise from the water, the fields of Lagunillas, Bacha-

quero, and Tía Juana are among the foremost producers. Oil is transshipped at Maracaibo, the capital of the state and Venezuela's second largest city. Leading agricultural products are sugarcane and rice, and livestock raising, particularly goat grazing, is extensive. Fine woods for building are found in the forests. The National University of Zulia is at Maracaibo, which also has an international airport owned by the government. Other airports in the state are owned by oil firms. Pop. (1950) 560,336.

ZULOAGA, sōō-lō-ā'gā, Félix, Mexican soldier and statesman: b. 1814; d. 1876. Having entered the National Guard as a lieutenant, he fought against the Yucatán secessionists in 1842-1843. Zuloaga at first supported Ignacio Comonfort (q.v.) when he became provisional president at the end of 1855, but he later turned against Comonfort's liberal policies and seized the presidency from him in January 1858. In the War of Reform that followed, Zuloaga was opposed by the Liberals, led by Benito Juárez. He was replaced in the presidency by the Conservative Miguel Miramón in February 1859. When the French invaded Mexico in 1861-1862, he left the country but returned in 1864 and tried unsuccessfully to overthrow Emperor Maximilian in 1865.

ZULOAGA (Y ZABALETA), thōō-lō-ā'gā ē thā-bā-lā'tā, Ignacio, Spanish painter: b. Eibar, Spain, July 26, 1870; d. Madrid, Oct. 30, 1945. He first studied architecture in Rome but soon shifted to Paris, where he turned to painting, being much influenced by Gauguin and Toulouse-Lautrec. Returning to Spain, he evolved a sad, somber, and often brutal style, which may be called his own only with the qualification that it is founded on El Greco, Francisco de Zurbarán, Velázquez, and Goya. Composite though he was, he was hailed as the founder of a new school of Spanish art. He visited the United States in 1924, when he turned temporarily to fashionable portraiture. He barely survived his great renown; he lived on as a respectable artist who began to make his reputation a decade before Picasso turned from charm to revolution. A most copious painter, Zuloaga is represented in many art galleries, notably in Barcelona, Brussels, Paris (Luxembourg), and New York City (Hispanic Society). Whatever their artistic worth, his paintings are redolent of Spain, and he lived his life as a Spaniard to the full, being a celebrated amateur bullfighter.

WALLACE BROCKWAY.

ZULU, zōō'lōō, the name applied to over 2½ million Bantu-speaking people who dwell in specially reserved tribal areas in the Natal and Transvaal provinces of the Republic of South Africa, as well as on farms owned by Europeans. Many of them move periodically to work in the mines and towns and then return to their rural homes. A large number of people of Zulu origin also are permanently settled in the towns. Originally Zulu was the name of a small tribe living near the Tugela River, one of a congeries of tribes known as the Nguni, which from at least the 15th century onward—and almost certainly for many centuries before that—inhabited the southeastern region of Africa. Each tribe numbered 2,000 to 10,000 members and was independent under its own chief. The people

spread across the land in order to cultivate their grains, herd their cattle, and hunt. As a tribe grew in size, some of its component sections would secede periodically into independence under a near or distant kinsman of the chief, a man who had previously been an officer of the chief in a graded, authoritative hierarchy. Some secessions were peaceful; others followed on rebellions in which a kinsman of the chief tried to seize the chieftainship and the defeated party moved into independence. Neighboring tribes were usually at peace with one another, though raids for cattle and ransom occurred.

Apparently no chief tried to enlarge his dominion by conquering his neighbors until around the period after 1775, when pressure on land and possibly other factors began to produce wars of conquest. Early in the 19th century Chaka (Shaka), chief of the Zulu, embarked on a bloody war of conquest of the whole region. He succeeded by abandoning the throwing javelin for a more powerful stabbing spear and by the development of new military tactics. He enrolled all his men in regiments grouped by age and housed them for a large part of the year in barracks, ruled by a female relative. Here they drilled to move in disciplined order. His aim was to encircle his enemy by advancing with veterans at the center of his army and young regiments as wide-thrown wings that closed behind the enemy. The soldiers were forbidden to marry until their middle thirties, so Chaka had a permanent fighting force, trained to maneuver and to fight at close quarters. In his early years, when he was relatively weak, he used scorched-earth and guerrilla tactics effectively; later he developed something like the Roman *testudo* (q.v.) to assail mountain fastnesses. His armies raided into distant regions, and his wars were so devastating that he killed and put to flight over 1 million people. Some fleeing tribes established their own kingdoms in several widespread and distant parts of Africa.

Chaka enlarged the power of the chieftainship and ruled despotically until he was assassinated in 1828 by two of his brothers, one of whom, Dingaan (q.v.; Dingane) became king. Dingaan was defeated first by the Boers in 1838 and then by another brother in 1840. The kingdom, with its barrack system filled with unused warriors, survived until its conquest by the British in 1879. From 1887 to 1889, the Zulu chief and his subordinate authorities became junior officials in the administrative system of their white conquerors.

ZULULAND, zōō'lōō-lānd, district, South Africa, in northeastern Natal Province, 10,362 square miles in area, inhabited mainly by the Zulu. It is bounded on the north and northwest by Mozambique and Swaziland, and on the south by the Tugela River. Zululand consists of a

A kraal (village) of mud huts in Zululand, showing typical horseshoe formation, with circular cattle enclosure in foreground.

Information Service of
South Africa

wide, often fertile coastal plain with a maximum width of 50 miles, and to the west a dissected semihighland area averaging about 2,000 feet in elevation. The latter is the traditional home of the Zulu, and Eshowe, the district capital, is found here.

Zululand's subtropical and well-watered climate is ideal for agriculture, but development has been handicapped by the land-reserve system. Approximately 86 percent of the native population resides in Zululand's 21 reserves (6,074 square miles); in many cases the reserves are so densely populated that only subsistence agriculture dominated by maize and livestock is possible. Most of the two major commercial crops, sugarcane and cotton, are grown on European lands, but expansion of these lands and crops, in turn, is limited by the native reserves. Other activities include the exploitation of wattle and eucalyptus. A paper mill at Mandini and scattered sugar mills make up Zululand's manufacturing. The beauty of the country and interest in the people's way of life contribute to tourism. Two rail lines and several motor roads radiate from Eshowe. The district boasts five game and several forest preserves.

The Zulu were a rather insignificant tribe until the early 19th century when Chaka (Shaka) became chief and, through despotism and conquest, built them into a powerful tribal unit. Chaka was murdered and succeeded by his brother Dingaan (q.v.; Dingane) in 1828. Ten years later Dingaan murdered 70 European voortrekkers who were negotiating with him for land. The voortrekkers under Andries Pretorius soon regrouped and in December 1838 broke Dingaan's power at the Battle of Blood River, killing 3,000 Zulu. The Zulu retreated into Zululand, built an impressive military force, and for 40 years remained relatively independent of European influence. Fear of Zulu attack on Natal prompted the British to issue an ultimatum to their chief, Cetewayo (q.v.; Cetywayo), to break up his military organization, but it went unheeded. In January 1879 British forces under the 2d Baron Chelmsford invaded Zululand and were soundly defeated at Isandhlwana, but Chelmsford returned in July and destroyed Zulu military power at Ulundi. To keep the area out of the hands of the Boers and Ger-

mans, the British placed it under a protectorate in 1887, and it was officially annexed to Natal in 1897. Pop. (1962) 470,000, including 456,000 Zulu.

ZUMÁRRAGA, thōō-mär'rä-gä, **Juan de**, Spanish prelate and first bishop of Mexico: b. Durango, Vizcaya Province, Spain, 1468; d. Mexico, June 3, 1548. He entered the Franciscan Order and was guardian of the convent of Abrojo in Spain. With the title of bishop-elect and protector of the Indians, he arrived in Mexico in 1528. He fought abuses by the secular authorities against the Indians and developed the Mexican missions, but misguidedly directed considerable zeal toward gathering and burning Aztec manuscripts. He was formally consecrated bishop of Mexico in 1533. His see was elevated to an archbishopric in July 1548, before news of his death had reached Rome.

ZUMBO, zōōm'bō, village, Mozambique, in the northwest, on the north bank of the Zambezi River at the Northern Rhodesian frontier, 220 miles west of Tete and 450 miles from the mouth of the Zambezi. Established as a trading post in the last part of the 17th century, it declined after a period of prosperity but has become partly revitalized in more recent years with the development of Mozambique and adjacent territories. The village mines coal and ships rice, manioc, and beans.

JOHN RALPH WILLIS, JR.

ZUNI, zōō'nē (officially **ZUNI PUEBLO**), village, New Mexico, in McKinley County, on the Zuni Indian Reservation, about 30 miles south of Gallup. It is a residential community of Pueblo Indian people, most of whom gain a living by agriculture and jewelry making. Located on the site of one of the ancient Seven Cities of Cibola, the present village was founded about 1700. The municipal government is by tribal council, with a governor elected for a two-year term. Population: 7,405.

FREDERICK J. DOCKSTADER.

ZUNI INDIANS, zōō'nyē, a tribe of North American Indians of the Zuniian linguistic stock living on a reservation in Valencia and McKinley counties, New Mexico. The name is a Spanish corruption of the Keresan *Súnyitsi*. The Indians call themselves Ashiwi, meaning "the flesh." With the Hopi of Arizona, these people retain more of their pre-Columbian culture than perhaps any other North American Indians. They are descendants of the people of ancient Cibola, first seen by Marcos de Niza in 1539; his glowing accounts of the Seven Cities of Gold spurred Francisco Vázquez de Coronado to visit them the next year. Spanish influence was strong until 1680, when the Zuni participated in the Pueblo Revolt; their aboriginal Pueblo culture has been dominant ever since that time.

The Zuni live by agriculture and are among the finest jewelry makers in the Southwest, being particularly noted for their mosaic work in shell, jet, and turquoise, all set in silver mountings. Formerly skilled in weaving and pottery making, they have allowed these arts to decline, with the result that almost no Zuni textiles or pottery are made today. Their magnificent costumed ceremonials, particularly the winter Shálako pageant, are familiar to many visitors and are equaled only by the Kachina and Snake dances of the neighboring Hopi. At the time of the 1680 revolt, the Spanish census reported a Zuni population of 2,500, which shrank to 1,400 following the epidemic of 1898-1899. Today the population at Zuni (q.v.), N.Mex., and its suburbs is over 3,500.

ZUNI MOUNTAINS, zōō'nē, mountain range, New Mexico, in Valencia and McKinley counties, on the Colorado Plateau, near the Arizona line, southeast of Gallup. The mountains comprise a domed uplift about 70 miles long and 30 miles wide. The highest peak is Lookout Mountain (9,110 feet). There are lava beds in the south and southeast portions of the range.

ZÚNIGA Y AZEVEDO, thōō'nyē-gā ē ä-thā-vā'thō, Gaspar de, CONDE DE MONTERREY, Spanish viceroy of Mexico and Peru; b. Andalusia, Spain, ?1540; d. Lima, Peru, Feb. 10, 1606. Having arrived in Mexico as viceroy on Nov. 5, 1595, he sent out exploration and colonization expeditions to Lower California in 1596 and to the present State of California in 1602, both under the command of Sebastián Vizcaino (q.v.). He also organized an expedition under Juan de Oñate (q.v.) to conquer what is now New Mexico in 1598. Zúñiga was noted for his fair administration of the Mexican colony, his protection of the Indians,

and his colonizing efforts. Monterey, Calif., and Monterey Bay are named in his honor. In 1603 he was appointed viceroy of Peru and began his administration there in 1604.

ZUNSER, tsōō'n'zar, Eliakum, Yiddish bard; b. Vilnyus, Lithuania, Oct. 13, 1836; d. New York, N.Y., Sept. 22, 1913. After a traditional Jewish education in Vilnyus he came under the influence of *Maskilim* (Men of Enlightenment) and composed philosophic poems in Hebrew and singable lyrics in Yiddish. In 1856 he was impressed into military service but was released within a few months. In 1857 he found employment as a braider in Kaunas and studied at Rabbi Israel Salanter's moral academy, where students were encouraged to concentrate on eternal verities in silent meditation.

Zunser's early suffering, years of hunger, and lonely wandering gave him a rich fund of experiences and brought him ever nearer to the common people, and he became the most popular *badchan* (folk singer) of his day. Russian Jews were familiar with his melodies and texts even before his first volume, *Shirim khadoshim* (1861), had appeared. Thereafter his fame grew as a wedding bard, a chanting moralist who sermonized while he entertained and improvised appropriate verses during different stages of the ceremony. His drama *Mekhiras Yosef*, written in 1872, anticipated the rise of the Yiddish theater under Abraham Goldfaden. The Russian pogroms of 1881 led him to advocate emigration. For BILU, the first pioneers who set out for Palestine, he composed in 1882 his most famous songs—*Die Sokhe*, *Die Blum*, and *Shivas Zion*. He himself fled to America in 1889, where he continued as a singer of social justice in the New World and as the sensitive interpreter of Jewish martyrdom in the Old World.

SOL LIPTZIN,
Professor of Germanic and Slavic Languages,
City College of the City University of New
York.

ZUNZ, tsōōnts, Leopold, German Jewish scholar; b. Detmold, Germany, Aug. 10, 1794; d. Berlin, March 17, 1886. He was the founder of the *Wissenschaft des Judentums* (science of Judaism), based on the application of modern scholarly research methods to the study of Jewish religion, history, ritual, and liturgy. His doctoral thesis *Etwas über die rabbinische Litteratur*, published in 1818, contained the outlines of what was at the time a completely new field of scholarly endeavor. In 1819 he became a cofounder of the Berlin Verein für Kultur und Wissenschaft der Juden and in 1823 editor of its journal. The society published his biography of Rashi, the medieval Bible and Talmud commentator. From 1826 to 1830 Zunz was head of the school of the Berlin Jewish Community, and from 1840 to 1850 principal of the Jewish Teachers' Seminary. His most significant book is *Die gottesdienstlichen Vorträge der Juden* (1832; *The Synagogical Lectures of the Jews*), considered to this day a classic work of research into the history of Jewish homiletics and exegesis. Among his other important works are a volume on the names of the Jews and several books on medieval Jewish liturgical poetry.

RAPHAEL PATAI,
Theodor Herzl Institute, New York City.

ZURBARÁN, thoor-bá-rán', Spanish painter; b. Fuente de Cantos, Estremadura, Spain, Nov. 7, 1598; d. Madrid, Aug. 27, 1664. Practically self-taught, except for an apprenticeship at 16 to a minor artificer of religious figures in Seville, Zurbarán nevertheless succeeded in becoming as a painter the mystic poet of the Counterreformation, as El Greco was its lyric dramatist. His major work (1629-1644), a contemplation of dissonances between the primal world of divine love and the elemental world of brute fact, begins with *St. Peter Nolasco Dreaming of a Heavenly Jerusalem* (Madrid); it includes *The Apotheosis of St. Thomas Aquinas* (1631; Seville), his most celebrated painting; *St. Hugh of Grenoble Visiting the Refectory* (1633; Seville); and *St. Francis Kneeling* (1639; London). In his late forties his considerable popularity yielded to Murillo's sentimental religiosities, and Zurbarán sacrificed his genius to do wholesale work for the vast South American market of church art, which frequently proved delinquent in payments. In 1658, deep in debt, he left Seville to join his friend Velázquez, who was court painter in Madrid.

Of Basque ancestry, Zurbarán combined a provincial mysticism with a fresh and direct observation of men and things, mindful of the hieratic intensity of Spain's most articulate and efficient saints, St. Ignatius of Loyola (*The Spiritual Exercises*) and St. Teresa of Ávila (*The Interior Castle*). His matchless paintings of monasticism rendered the internal and external aspects of the dedicated life in lateral movement, in contrast to the syncopated spirals of El Greco. He placed monks and saints "half in and half out of doors," in the manner that Gertrude Stein disposed St. Teresa in *Four Saints in Three Acts* (1934), or he had them "laterally be lined," like the Jesuit followers of St. Ignatius in the Stein opera. He insisted on setting the rough, earthy look of things, their *bodegón* (tavern still life) values, in counterpoint to a sober architecture of form and a Venetian resonance of color. In his tenebrist canvases, shapes are at once settled to stay and ready to go. He is imperious with vermilion, blue, and gold, with rose and orange and manifold white; austere with Spanish blue-gray and blue-green hues; and sturdy with the blue-red slate of Spanish earth. Like Goya and Manet two centuries later, like Henri Rousseau and Picasso in the 20th century, he used the technique of applying colors at full intensity in order to achieve an archaic strength and plainness.

Zurbarán, like Michelangelo da Caravaggio, filled his pictures with darkness rather than with light, but he also added to the baroque a quality of profound meditation. In his portraits of starved and threadbare male saints, spirit assaults the sinews of the flesh; in his female saints, so elegant in silks and velvets, spirit redeems the ideals of the flesh. If the paintings of the male saints are prayers made palpable in the dark corners of desolation, the paintings of the female saints are like pagan temples transformed into Roman churches, such as Santa Maria sopra Minerva or Santa Maria in Cosmedin, once sacred to Mercury and Ceres. Examples of these paintings are the *St. Margaret* (1632; London), *St. Peter* (1633; Lisbon), *St. Simon* (1633; Lisbon), and *St. Apollonia* (1636; Paris).

In his work for the white-robed monastic orders Zurbarán, using impasted whites, achieved his subtlest inflections as a painter. The series of

scenes for the Carthusian monastery in Jerez (1637-1639; several in Cadiz Museum), the martyrdoms for the Mercedarian cloister in Seville (1636-1638; now scattered in private collections), and above all the 11 large and 10 small paintings for the Hieronymite monastery in Guadalupe (1638-1639) are accomplished in whites that are,

by turns, hard as stone, soft as pith, heavy as frost, and always deep as the solitude of his subjects, "alone with the Alone." Their miraculous: hush of whiteness, like a polar light, a cloud, an eagle feather, is a firm abstract of Zurbarán's art and mysticism. American museums with examples of his work include the Boston Fine Arts, Chicago Art Institute, Hartford Wadsworth Atheneum, New York Metropolitan, and San Diego Fine Arts. *The Holy House of Nazareth* (c. 1630) can be seen at the Museum of Art, Cleveland, Ohio; and one of his few portraits, the *Doctor of Laws* (c. 1658-1660), is in the Isabella Stewart Gardner Museum, Boston.

PHILIP RODDMAN.

ZÜRICH, tsü'rikh, canton, Switzerland, bounded on the north by Schaffhausen and the Rhine River, which constitutes the border with Germany, and by the cantons of Aargau on the west, Zug on the south, and Thurgau and St. Gallen on the east. The area is 668 square miles. The Lake of Zürich, which forms part of the southern boundary, reaches north into the canton; the city of Zürich, the cantonal capital, lies at its north end. The land surface of the canton is rolling, cut by valleys of rivers that drain northwest to the Rhine, and the maximum elevation is less than 4,000 feet. Corn and other cereals and fruit are grown in cultivated regions, and there are some wooded areas. Manufacturing, primarily of machinery and textiles, is concentrated principally in Zürich and Winterthur. There are hydroelectric plants along

A view of Zürich, showing the Limmat River, which flows through the city into the Lake of Zürich.

Authenticated News
International

the Rhine. The people are chiefly Protestant and German speaking, and their laws and customs are Germanic. In earliest times, the lake valley was a migration route and later an artery of trade, and the easy contours of the land encouraged settlement. Conquests by the city of Zürich created the modern canton. It was admitted to the Swiss Confederation in 1351 and after a 10-year separation during an alliance with Austria, was readmitted in 1450. A new democratic constitution, with town and country on an equal footing, was adopted in 1869. Pop. (1960) 952,304.

ZÜRICH, city, Switzerland, capital of Zürich Canton, at the north end of the Lake of Zürich, on both sides of the Limmat River and a tributary, the Sihl, 60 miles northeast of Bern. The largest city in Switzerland, cosmopolitan in character, it is the principal center of industry, trade, banking, and travel, and fosters a vigorous intellectual life in its educational and cultural institutions. Its setting is attractive, with wooded hills around the valley, and on clear days the snow-capped Alps are visible down the lake. The city is a blend of ancient and modern, with fine old houses on both sides of the Limmat, which leaves the lake here, and broad streets and plazas bordered by office buildings and shops in the newer sections. Residences cluster along the lake below the Utlberg, to the southwest, and the Zürichberg, to the east, while industry is concentrated in the northern part of the city. Manufactures include automobiles, radios, machinery, paper, woolen and silk textiles, chemicals, cement, canned products, beer, flour, and pastry. Printing and publishing are important. The Zürich International Airport is at Kloten, six miles from the city.

The University of Zürich and the Federal Institute of Technology draw many foreign students. The Swiss National Museum houses a distinctive collection of antiquities and historical material, and the Art Gallery is notable. The Protestant Cathedral, or Grossmünster, was built in the 11th to 13th century. St. Peter's Church and the Fraumünster date from the 13th century. In April is held the city's traditional festival, the *Sechseläuten*, with a procession of the guilds.

Lake dwellers, in pile-supported houses, were the earliest occupants of the city's site, and later there was a settlement of the Celtic Helvetii. The name is believed to derive from the Celtic *dur*,

meaning "water." Successive conquerors were the Romans (about 58 B.C.), the Alemanni (3d century A.D.), and the Franks, whose kings had a residence here. The medieval town became a free imperial city in 1218 and joined the Swiss Confederation in 1351. In the 16th century Zürich was the wellspring of the Swiss Reformation. Pop. (1960) 440,170.

ZÜRICH, Lake of, lake, Switzerland, bordered by the cantons of Zürich, Schwyz, and St. Gallen, about 25 miles long and up to 2½ miles wide, with an area of 34 square miles and a maximum depth of 469 feet. Near the east end a viaduct 1,017 yards long crosses the lake from Rapperswil on the north shore to Hurden on the south, carrying rail and road traffic. East of the causeway the lake is known as Obersee. At the east end the Linth River enters through the Linth Canal, which connects with the Lake of Wallenstadt. The Limmat River flows from the lake at the north end at the city of Zürich. Gentle hills covered with orchards, vineyards, and gardens surround the lake. Along the shore are many villages and villas and some industrial establishments. Southwest of Rapperswil lies the small island of Ufenau, where Ulrich von Hutten, satirical writer and supporter of Martin Luther, died in 1523 and is buried.

ZÜRICH, University of, an institution of higher learning in Zürich, Switzerland, founded in 1833. There are six faculties: divinity, law, medicine, veterinary medicine, arts, and science. Doctor's degrees are awarded, and a diploma (*Lizentiat*) is also obtainable in the faculties of law, arts, and science. The library contains about 1,200,000 volumes. There are some 60 student organizations, appealing to scientific, cultural, and social interests. Average annual enrollment is about 3,700.

ZUTPHEN, zút'fən (also ZUTFEN), town, the Netherlands, in Gelderland Province, in the northeastern part of the country, where the Berkel River meets the IJssel near the western end of the Twente Canal, 16 miles northeast of Arnhem. It is a dairy and lumber center, with some light manufacturing and plants processing meat and tobacco.

During the Middle Ages, when the IJssel was a trade artery between the Rhineland and the

North Sea, Zutphen was an important commercial center and a member of the Hanseatic League. Its commerce declined in the 16th century, when during the Dutch wars of independence it was twice captured by the Spaniards (1572, 1583) and its population massacred. The English poet and soldier, Sir Philip Sidney, was fatally wounded at Zutphen in 1586 while aiding the Dutch.

Zutphen is a town of winding streets and old gabled houses, with traces of its early fortifications remaining. The Gothic church of St. Walburga (Grote Kerk) was founded in 1105 and rebuilt after 1446. Its magnificently proportioned interior contains medieval frescoes, a baptismal font in copper (1527), and a 15th century Gothic chandelier. Adjacent is the library of the Grote Kerk; completed in 1564, it houses a collection of medieval books and manuscripts that are chained to reading desks as in the 16th century. The Stads wijnhuis, or city winehouse (1618-1627), is a reminder of Zutphen's former importance as an entrepôt for Rhenish wine export. Pop. (1957) 24,220.

ZUYDER ZEE. See **ZUIDER ZEE.**

ZWEIBRÜCKEN, tsvi'brük-ən, city, Germany, in the State of Rhineland-Palatinate, on the Schwarzbach River, 54 miles southwest of Mannheim. The name means "two bridges." The city has machine, textile, wood, and shoe industries, an agricultural college, and a famous library (Bibliotheca Bipontina) with valuable old manuscripts (see **BIPONT EDITIONS**). During World War II, Zweibrücken was 86 percent destroyed, including the baroque Ducal Castle (1720-1730) and the Late Gothic Alexander Church (1493-1507). It was chartered as a city in 1352 and was the capital of the Duchy of Pfalz-Zweibrücken from 1410 to 1799. After World War II the city was included in the Federal Republic of Germany (West Germany). Pop. (1961) 32,900.

ZWEIG, tsvīkh, **Arnold**, German novelist and dramatist: b. Glogau (Pol. Głogów), Silesia, Nov. 10, 1887. He became known as a novelist with his sensitive *Novellen um Claudia* (1912; Eng. tr., *Claudia*, 1930) and as a dramatist with his *Ritualmord in Ungarn* (1914), revised as *Die Sendung Semaels* (1918). His World War I experiences in northern France and on the Russian front found expression in his cycle of prose epics *Der Streit um den Sergeanten Grischa* (1927; Eng. tr., *The Case of Sergeant Grischa*, 1927), *Junge Frau von 1914* (1931; Eng. tr., *Young Woman of 1914*, 1932), *Erziehung vor Verdun* (1935; Eng. tr., *Education Before Verdun*, 1936), *Einsetzung eines Königs* (1937; Eng. tr., *The Crowning of a King*, 1938), and *Die Feuerpause* (1954; *Armistice*). Most influential was the first, which was translated into many languages and paved the way for the still greater vogue of Erich Maria Remarque's war novels. The central character is an inarticulate, simple-minded Russian prisoner of war whose unimportant life and mistaken end challenged the entire Prussian system of administering justice.

An early adherent of Zionism, Zweig recorded his observations of the Jewish scene in the essays in *Galiban* (1927) and *Bilanz der deutschen Judenheit* (1934; Eng. tr., *Insulted and Exiled*, 1937) and in the novel *De Vriendt kehrt heim* (1932; Eng. tr., *De Vriendt Goes Home*, 1933). He was exiled from his Berlin home in 1933 be-

cause of his Jewish origin and settled in Haifa, Palestine. There, despite failing eyesight, he completed *Das Beil von Wandsbeck* (1946; Eng. tr., *The Axe of Wandsbeck*, 1947), a novel depicting Nazi terrorism. He was unable to adjust to Palestinian realities, however, during the strife-torn years that preceded Israel's independence, and returned to East Berlin in 1948. There he served as president of the Academy of Arts in 1949-1952. He died in East Berlin on Nov. 26, 1968.

Zweig's later works include *Five Romances* (1959); a volume of poems, *Jahresringe* (1963); and *Essays I and II* (1959, 1967). He was awarded the Lenin Peace Prize in 1958.

of German Literature."

ZWEIG, Stefan, Austrian writer: b. Vienna, Austria, Nov. 28, 1881; d. Petrópolis, Brazil, Feb. 23, 1942. Offspring of a patrician Jewish family, he was educated at the universities of Berlin and Vienna and began his career with the lyric volumes *Silberne Saiten* (1901) and *Die frühen Kränze* (1907). Travels in Africa, Asia, and America gave him world perspective. In the circle of the Belgian poet Émile Verhaeren, whom he translated into German, he came in contact with the literary elite of western Europe and projected for himself the role of the "good European," the sympathetic intermediary between the cultures and great personalities of the Continent. He drew upon Hellenic sources for his first drama *Tersites* (1907) and upon Biblical sources for his pacifist play *Jeremias* (1917), which warned against the folly of war and comforted the defeated. His short stories followed the contemporary tradition of "Young Vienna" and were especially influenced by Arthur Schnitzler and Sigmund Freud.

Zweig reached the height of popularity with his biographies and cultural essays. His studies of Dostoyevsky and Tolstoy made the Russian soul more intelligible to the West. In Romain Rolland, Honoré Balzac, Stendhal, Joseph Fouché, and Marie Antoinette he sought to interpret the French soul. In other studies he appraised sympathetically the achievements of diverse peoples and ages. He adapted Ben Jonson's *Volpone* for contemporary audiences and wrote opera librettos for Richard Strauss. Deprived of his home in Salzburg and forced into exile because of his Jewish origin, he was unable to establish new roots and committed suicide in Brazil. His autobiography *Die Welt von Gestern* (1941; Eng. tr., *The World of Yesterday*, 1943) affords keen in-

Stefan Zweig

Brown Brothers

sight into his personality and the European culture of his generation.

SOL LITZIN.

ZWICKAU, tsvik'ou, city, Germany, on the Zwickauer Mulde River, 40 miles south of Leipzig. Its industry is based on rich coalfields nearby. There is also manufacturing of small motor cars, textile goods, dyes, chemical products, and ceramics. Zwickau has an Institute of Technology with a special Department of Mining. Its historic buildings include the Church of St. Mary (Marienkirche), dedicated in 1118, altered in the Late Gothic style in 1505–1537, and containing a painting of Christ by Lucas Cranach the Elder; St. Catherine's Church (Katharinenkirche), begun in 1212 and rebuilt in Late Gothic style; the City Hall (Rathaus), of the 15th century; and the Late Gothic Gewandhaus (Clothworkers' Hall), built in 1522–1536, part of which has been converted into a theater. The Oberstein Castle (1565–1585) has been turned into a penitentiary.

Zwickau was first mentioned in 1118 and was a free imperial city from 1290 until 1323, when it was taken over by the margraves of Meissen. It was famous for its silver mines after 1470, and for its Latin college. The Anabaptist movement of the German Reformation was founded by Thomas Münzer in Zwickau in 1520 (see ANABAPTISTS). The city was the birthplace of the composer Robert Schumann (1810–1856). After World War II Zwickau was included in the Karl-Marx-Stadt district of East Germany. Pop (1979 est.) 123,475.

ZWINGLI, tsving'lē, Ulrich (or Huldreich), first Protestant reformer of Switzerland; b. Wildhaus, St. Gallen Canton, Switzerland, Jan. 1, 1484; d. Kappel am Albis, Zürich Canton, Oct. 11, 1531. The third of eight sons of a comparatively well-to-do bailiff, he was designated by his father at an early age for a career in the church. He studied in Basel, Bern, and Vienna and completed his training in the arts and in theology at Basel (1502–1506), where he obtained the degree of M.A. He was already a persuaded humanist when in 1506 he was called upon to serve as parish priest of Glarus. There Zwingli turned to Biblical studies, reading the New Testament in Greek and carried on a valued correspondence with Erasmus. He gradually came to regard himself as an Erasmian.

He also began to think that the church should be reformed by a restoration of its original order. Yet he was a faithful churchman, loyal to the pope. As such he served as chaplain to the

young men of Glarus who had engaged as mercenaries for the pope in defense of northern Italy against the French, and was present at the victory of Novara in 1513 and the defeat of Marignano in 1515.

In 1516 Zwingli became preacher in the convent of Einsiedeln, then as now a celebrated place of pilgrimage, and began to give public expression to his ideas of reform of the church upon those points in which he believed it had departed from the primitive teaching. He gained considerable fame as a pulpit orator, so that in 1518 the chapter of the Grossmünster (cathedral) of Zürich invited him to become the people's priest (preacher) there. He assumed his new duties in January 1519 and delivered a series of sermons in which he expounded seriatim entire books of the New Testament, beginning with the Gospel according to Matthew, hoping to instill in his hearers the desire for a reform of the church and the common life according to the pattern of the New Testament. A little later, he began to object to the efforts of foreign agents to secure popular support for the recruitment of Switzerland's young men as mercenaries, and did not hesitate to inveigh against papal policies in this connection. In December 1518 he came under the influence of Martin Luther's early writings and the next year became a partisan of Luther's cause, both in respect to the new understanding of the Gospel in terms of trusting faith in the divine promise of forgiveness and in respect to the criticism of the papacy as an enemy of Christ.

Reformation in Zürich.—Under Zwingli's leadership, Zürich gradually became a second center of the Reformation, next to Wittenberg. This was possible only because Zwingli had secured the government's support for his enterprise. In 1520 the Zürich Council published a decree ordering that the Holy Scriptures should be taught "without human additions." In 1522 Zwingli began to abolish Roman Catholic ceremonies and wrote a treatise against fasting.

The government issued a call for a "disputation," a public discussion by theologians and churchmen, to test the truth of Zwingli's teachings. Zwingli prepared 67 *Schlussreden*, or proofs, in which he set forth his program for the reform of the church. On Jan. 29, 1523, the disputation took place, with Johannes Faber, vicar-general of the bishop of Constance, as the most prominent Roman Catholic representative. Faber refused to discuss any of Zwingli's propositions except the last, which denied the supreme authority of the hierarchy of the church. The Council decreed that Zwingli had not been convicted of error. On Oct. 26–28, 1523, a second disputation was held, as a consequence of which the Roman Catholic order in Zürich was gradually abolished. The monasteries were closed; ecclesiastical funds and properties were assigned to educational purposes and poor relief; and jurisdiction over marriage and divorce was assigned to a special court. By Easter 1525 the Mass and all other Roman Catholic sacraments and ceremonies were abolished and replaced by a preaching service and the simple observance of the sacraments of Baptism and the Lord's Supper according to the pattern of the New Testament.

Zwingli interpreted the Lord's Supper as a memorial feast, by the observance of which Christian believers, assembled as a local congregation, affirm their faith in Christ and renew their fealty to him. He denied the real presence of Christ in

Ulrich Zwingli

The Bettmann Archive

the bread and wine of the Eucharist and rejected the doctrine of transubstantiation. He affirmed a spiritual presence of Christ in terms of the sixth chapter of the Gospel of John. Zwingli set forth the theological reasons for all these innovations in his main theological work, characteristically entitled *Commentarius de vera et falsa religione* (1525; Commentary on True and False Religion). His doctrine was marked by a distinctive emphasis on the sovereignty of God, in connection with which he tended to view the Bible as the "Word of God" in a legalistic way. Moreover, he taught the doctrine of predestination as the basis and source of salvation, and he interpreted all forms of life as manifestations of God's providence.

Opposition to Zwingli. Zwingli encountered opposition from several quarters—from the Anabaptists, the Lutherans, and the Roman Catholics. The Anabaptists, who came publicly to the fore in Zürich for the first time late in January 1525, were originally followers of Zwingli, but they felt it necessary to part company with him because of his advocacy of a theocratic church order; they regarded his alliance with the political authorities of Zürich as irreconcilable with Christian teachings. Another controversy in which he became involved was due to the fact that his conception of the Lord's Supper called forth vehement opposition on the part of Luther, who, though rejecting transubstantiation, ardently believed in the real presence of Christ in the elements of the Lord's Supper. In the interest of forming a united evangelical front against the Roman Church and her political defenders, especially the Habsburgs, a colloquy was arranged at Marburg on Oct. 1–3, 1529, under the auspices of Philip, landgrave of Hesse. Luther, Zwingli, and the other Protestant theologians present readily agreed on the main Christian doctrines but found it impossible to achieve a common mind on the Lord's Supper.

The third major conflict in which Zwingli was involved was with the Roman Church and especially with its defenders in Switzerland. The five oldest cantons of the Swiss Federation, the so-called Forest (rural) Cantons, adhered strictly to Roman Catholicism and objected to the spread of the Reformation in the urban cantons. Under the leadership of Zwingli, Zürich imposed political and economic sanctions on the old cantons, and in the fall of 1531 they made a surprise attack on the city. Zwingli went to battle as a chaplain with the Zürich soldiers and was struck down in the fighting at Kappel am Albis, in Zurich Canton, on Oct. 11, 1531. His cause was taken up by his followers, and his work was carried on by his successor, Heinrich Bullinger.

ZITTERION, tsvit'ər-i-ən (from Ger. *zitter*, hybrid, + *ion*), an electrically neutral organic molecule that has a positive charge at one end and a negative charge at the other. A zwitterion, also called dipolar ion, hybrid ion, or amphion, thus has an electric dipole moment. Amino acids and proteins often exist in the form of zwitterions.

One of the simplest examples is the amino acid known as glycine, $\text{NH}_2\text{—CH}_2\text{—COOH}$. In aqueous solution the —COOH (carboxyl) group at one end of the glycine molecule dissociates: $\text{COOH} \rightarrow \text{CO}_2^- + \text{H}^+$. At the other end of the molecule the —NH_2 (amino) group acquires a hydrogen ion: $\text{NH}_2 + \text{H}^+ \rightarrow \text{NH}_3^+$. This results in the zwitterion $^+\text{NH}_3\text{—CH}_2\text{—CO}_2^-$. In the crystalline form of glycine the hydrogen of the carboxyl group is transferred to the amino group, so that the zwitterion also exists in the solid state. The dipole moments of zwitterions can be measured with appropriate equipment.

ZWOLLE, zvól'ə, town, the Netherlands, capital of Overijssel Province, in the north central part of the country, at the junction of the Zwartewater River and Overijssel Canal, 18 miles north of Deventer. It is a market town and railway and highway junction, and produces chemicals, metalware, clothing, edible fats, and dairy products.

Although the town dates from 1040 and received its charter in 1233, it did not become commercially important until the beginning of the 16th century. It was a leading Dutch stronghold during the wars of independence (1568–1648), but its defenses were destroyed in 1674 by the bishops of Münster and Cologne, allies of Louis XIV of France. The old star-shaped fortifications have been converted into parks, outlined by canals that occupy the moats.

During the Middle Ages, Zwolle was a cultural center, with famous convents and a celebrated school. On nearby Agnietenberg was a monastery where Thomas a Kempis (q.v.) lived from 1407 until his death. Many 15th and 16th century buildings have survived, among them the Gothic Grote Kerk (cathedral), the town hall, and the Sassenpoort, a high gateway with four octagonal towers. Pop. (1980) 82,190.

ZWORYKIN, zwôr'i-kin, Vladimir Kosma (1889–1982), Russian-American engineer. He was born in Murom, Russia, on July 30, 1889. As a student at the Institute of Technology in Petrograd (Leningrad), he became fascinated with the possibility of creating a practical television system. After the Bolshevik Revolution in Russia, he moved to the United States in 1919 and became a citizen in 1924. After some years with the Westinghouse company, Zworykin became a research scientist for the Radio Corporation of America (RCA) in 1929. He is the inventor of the iconoscope, the first practical "pickup" tube for television, and he directed the research that led to the development of the kinescope. He was also instrumental in perfecting the electron microscope, one of the most powerful tools of medical and biological research. In 1957 he patented a device that utilizes ultraviolet light and television to permit a color picture of living cells in action to be thrown upon a screen, opening new possibilities for biological research. He retired as director of electronics research for RCA in 1954 with the title of honorary vice president and continued to serve as a consultant. In 1966 he was awarded the National Medal of Science. He died in Princeton, N.J., on July 29, 1982.
